

THE
JOURNAL OF HORTICULTURE,
COTTAGE GARDENER,

AND
COUNTRY GENTLEMAN.

A MAGAZINE OF GARDENING, RURAL AND DOMESTIC ECONOMY, BOTANY AND
NATURAL HISTORY.

CONDUCTED BY

GEORGE W. JOHNSON, F.R.H.S., AND ROBERT HOGG, LL.D.

THE FRUIT AND KITCHEN GARDENS, by Mr. J. Robson,
Gardener to Viscount Holmesdale, M.P., Linton Park; and Mr.
T. Weaver, Gardener to the Warden of Winchester College.

THE FLOWER GARDEN, by Mr. G. Abbey, Stansty Hall; and
Mr. J. Wills, Gardener at Huntroyde Park, Burnley.

STOVE, GREENHOUSE, and WINDOW GARDEN, by Mr. R. Fish,
Gardener, Putteridge Bury, near Luton.

FLORISTS' FLOWERS AND FLORICULTURE, by the Rev. H. H.
Dombrain.

GARDENING CALENDAR, by Mr. William Keene.

POULTRY-KEEPING, by Mr. J. Baily, Rev. W. W. Wingfield,
E. Hewitt, Esq., and other well-known contributors.

BEE-KEEPING, by H. Taylor, Esq.; T. W. Woodbury, Esq.;
"E. & W.;" and Mr. S. Bevan Fox.

HOUSEHOLD ARTS, by the Authoress of "My Flowers," and
others.

TO OUR READERS.

WE have seen a ballad, whether a plagiarism of "Chevy Chase," or "Chevy Chase" a plagiarism of it, we leave to your determination—for you will recollect how often the ancients have robbed and forestalled us—saying things we should have said, and doing things we should have done, had they not thrust themselves in before us. The ballad begins thus—

" God prosper long our noble Queen,
Our flowers, and fruits, and all,
A Show of which was lately seen,
Called ' International.'
Sir Wentworth, sturdy knight, was there ;
Sir Daniel, brisk was he ;
And Moore, and Hogg, and Masters too,
Each busy as a bee."

The ballad then in detail, fuller than this brief page will admit, proceeds to enumerate the floral forces marshalled under various leaders—

" Proud Orchids led by Veitch, were there,
And Roses, led by Paul ;
Azaleas by Turner—but
We cannot name them all."

The bard then changes the scene to the Guildhall, describes the feast, and goes on to observe—

" The banquet o'er—the guests all gone—
The servitors away—
And aching heads bemoaned next morn
What stomachs did that day."

The ballad does not, as might be expected, there close, but goes on to record a conversation that took place when all was quiet between Gog and Magog. The latter was unable to make out who the guests were.

" Lean men they were, and men of sense,
With appetites so small ;
Some German talk'd, and some talk'd French—
Aldermanic not at all."

Gog, however—evidently a better informed Giant, and certainly a good judge—enlightens his brother, and explains who everybody was. Amongst others

" THE COTTAGE GARDENER was here—
Or GARDENERS I should say :
Its staff 's a legion world-wide spread,
And its Editors are tway."

Gog then pays us compliments which would turn our ink red to print, concluding, as we will, with this mingling of the true and the prophetic—

" Our masters read it—almost all :
'Tis Copeland's ' Tuesday's treat ;'
And Mechi has it yearly down
In his fam'd ' balance-sheet.'
He says, ' It 's better ev'ry year,
Its volumes thirty-four ;
And, Cumming being once more wrong,
They 'll be as many more.' "

INDEX.

ABERDEEN POULTRY SHOW, 36, 58
Acacias—for pot-culture, 229; pubescens not flowering, 316; dealbata unhealthy, 353
Achillea Clavenna, 389
Achilleas—seedlings, 13; culture, 41
Acrida odoratum spotted, 316
Aschyranthus splendens, culture of, 353
Air-giving, 149, 407
Alocasia metallica culture, 333
Allotment gardening, prize for, 286
Amaryllis seedlings, 12
Amaranthus tricolor, 289
American plants exhibited, 432, 434
Amherstia nobilis, 219, 240; flowering, 161
Ammonia water in vinery, 424
Anacochilus Domini, 153
Andalusian fowls, 176
Annals—for border, 72; a few good, 177; sowing, 207; to bloom in August, 263; half-bardy, sowing, 315
Antennaria margaritacea and **tomentosa**, 389
Antipodes, horticultural exhibition at, 405
Ants—banishing, 139; in orchard-house, 248; black, to drive away, 355; in flower-pots, 446
Aphelexis culture, 139
Aphis, brown, destroying, 331
Apples—trees insected, 73; cutting for grafting, 132; in orchards, 357; fruit gathered in January, 85; pips sowing, 91; stocks for, 124; list of, 132; Calville Blanche, 140; Newtown and Paradise Pippins, 228; Pommier de Paradis as a stock, 124, 255; in Pear stocks, 264; merits of stocks for, 269; in French Paradise, 370
Apricots—pruning, 316; not fruiting, 370
Aquatic plants for out of doors, 386
Arctotis argentea, 389
Artemisia argentea, 389
Artichokes, 462
Ash—training a weeping, 207; Black, 366
Asparagus—heads, 51; salt for, 296; for London market, 133; culture, 204
Asters in pots, 445
Aucuba—japonica fruited as a dinner-table plant, 27; berries, sowing, 113; japonica variegata, 125
Auriculas, 123; Gem and King of the Crimson, 440
Aylesbury drakes, distinguishing, 120
Azaleas—watering foliage, 12; list of, 95; growing prematurely, 133; new hybrid, 100; repotting, 264; thrives on, 264; management of, in a room, 409; after blooming, 444; at the International Horticultural Exhibition, 454; cuttings, 462

BALA-POOL, 247
Balkan, hints on culture of, 339
Bank, Roses and Laurels on, 32
Banquet at the Guildhall, 401
Bantams—overfed, 40; breeding Sebright, 20; Game, 35, 134, 153, 172, 191, 209, 230; with Cochins, 266; Russian, with Fringe Coors, 300; rearing Black, 374; falling back wards, 388
Barley-meal as food for fowls, 412
Barometer, a natural, 454
Baskets on a lawn, 273
Basswood, 366
Batemanda grandiflora, 257

Bath and West of England Society's Poultry Show, 416, 434
Bauhinia tomentosa glabra, 125
Beds—planting circular, 9; plants for, 353
Bedding out, 207; plants, wintering, 85; notes on, 257
Bedding plants, white, 870
Bees—"B. & W.'s" apiary, honey harvest, 19; dysentery, pollen-gathering on Christmas-day, feeding rescued, 20; foul brood, 39; dysentery, Ligurians crossed with black, crown-boards, cleaning floor-board, 40; foul brood, 59; winter ventilation, dysentery, 60; "B. & W.'s" apiary in 1865, 80; apiarian notes, 81; dropsy in, driving, mouldy combs, 82; queen encasements, 36; Ligurians, stand, aspect, 38; reciprocal attacks, queen encasements, 120; pollen-gathering in Scotland, 135; apiarian notes, 136; Woodbury hive, house, 136; hive-making, night excursions, 156; frame-hives, foul brood in America, cure for dysentery, 157; fountains, pollen gathering, flowers, hiving, 158; apiarian notes, 175; driving without reversing, dropsy in, uniting stocks, 176; hives making, 191; Ligurian, honey harvest, opening a Woodbury hive, spring feeding, dysentery, 192; in American cities, Ligurians, supers and collaterals, wintering, longevity, 211; transferring Woodbury hives, common and Ligurian in one apiary, 212; comparative longevity, Woodbury hives, 235; feeding hives for profit, altering a Nutt's hive, how we introduced Italians without losing them, 234; preventing swarming, removing stocks, 250; improved frame, 265; changing a Nutt's to a bar hive, Ligurians in Palestine, 266; in Palestine, hunger swarm, dysentery, 281; feeding and shifting, 282; longevity of Ligurian and black, improved frame hives, catching, titmice, 282; their recollection, 299; improved frame hive, managing Ligurian, preventing swarms escaping, prosperous, which is the best hive? 300; burying a hive, removing by rail, 320; in Holy Land, fertile workers, combs broken down, 355; tomtit, improved frame hive, ceased working, cleaning, 336; swarming, immunity of, the tomtit a foe to, early swarms, frame hives, Ligurian, mistaking a hive, 356; rymenal a substitute for pollen? 373; novitiate in keeping, frame hives, guide combs, 374; Ligurian, tomtits eaters of, early swarm, 388; "The Apiary, or Bees, Bee Hives, and Bee Culture," apparatus eating, do swarms ever issue before drones appear? 411; wintered in the uncomb-hive, 412; artificial swarms, hardness of Ligurian, early swarms, treble swarm, tomtits, 428; supers and swarming, retaining, supers after swarming, 448; artificial swarms, strengthening stocks, my apiary, 465; preventing drone-breeding, cutting out combs, 466; queen removed in a snapper, removing from a wall, weight of swarms, care in driving, 485; management of supers, apertures eating, apertensions concerning, Ligurians & black, 486

Beginners, hints to, 71
Begonias—baccata, 67; for winter flowering, 170; not flowering, 317; leaf-propagating, 370; geranioides, 440
Belladonna Lily, turning out, 279
Beverly Poultry Show, 426
Bingley Hall, first impressions of, 34, 54
Birmingham—awards, 14; Columbarian and Bird Show, 174; Rose Show, 455
Blackbirds—rearing by hand, 336; a talking, 427; musical, 466
Blossoms, siding in fertilising, 230
Boilers, 106, 166, 325, 333; heating two houses from a tubular, 53; upright tubular, 184
Boia immortel, 151
Botanic (Royal) Society's Shows, 220, 272, 306, 369, 434
Botany, its advantages to horticulture, 400; and horticulture, the advantages of their association, 401
Botanical Congress Essays, 436, 452
Bougainvillea speciosa culture, 317
Bouquet, Princess Mary's, 451
Box-edging planting, 94
Brahmas, 234, 250; and Hamburgs, a cross between, 176; breathing with difficulty, 466
Breeding poultry, 212
Bridgesia spicata bardy, 54
Broccoli—seed, obtaining pure, 325; stocks, 443
Bruzansia suaveolens—culture, 317; buds falling, 445
Buckwheat, 234; for fowls, 82; sowing, 916
Bull forcing, 10, 20
Bull-dog, "King Dick," death of, 427
Bullfinches, rearing young, 486
Bulls, new plants at, 339
Butter—pale in winter, 98; yellow in winter, 158; fckleness of, 212
Buttermilk for Figs, 120

CABBAGE AND DITTO, 424
Caladiums, aphides on, 277
Calathea Veitchii, 125
Calceolarias—culture of herbaceous, 4; cuttings, 93, 316; not striking, 263
Calico substitute for glass, 333
Camassia esculenta culture, 386
Camellias—culture, 53, 159; buds and leaves falling, 73; leaves spotted, 74; large standard, 140; out of doors, 183; flowers poor, 223; potting, 247; leaves browned, 263; repotting, 264; Nonpareil, 440
Canaries—Goldfinch male breeding, 136; dying, 158, 212; pecking the cage wires, 212
Canes, 438
Cannanica, 371
Cardinal, food for, 856
Carnations, transplanting, 54
Ceanothus pruning, 446
Cedar, white, 366; of Goa, 370
Cedronella canariensis, 317
Celery on damp soil, 132; liquid manure for, 379; planting, 460
Centaurea, 349
Cerastium tomentosum and **Biebersteini**, 859
Ceropegia sororia, 865
Chamber under glass structure, 112
Chamaeranthemum Leycehii var. **virgata**, 125
Cherries, 490; grub-eaten, 278; netting for, 317; at Canterbury, New Zealand, 344

Chelanthos odora culture, 346
Chickens—marking, 234, 418; hatching, 234; dying, 282; during cold weather, 374
Chimney, one for two houses, 249
Chimonanthus fragrans in pots, 152
Chrysanthemums—Iona, John Salter, 125; Pompone, 257; new, 359
Church, beating a, 247
Churn, zinc in, 282
Chierarias—without petals, 72; seedlings, 170; attacked by aphides, 279; culture, 337; maritime culture, 266, 389
Chireester Poultry Show, 387, 410
Citron trees unhealthy, 32
Clay soil, improving, 32
Cleodendron Thomsons culture, 132
Clanthus Danpieri, var. **marginata**, 67
Cochin-Chinas—cock's comb, 20; culture books in, deficient in size, 39; culture-booked, 59, 80, 119; excrescence in comb, 82; scaly legged, 212; black, 212; Buff, 234; not laying, 300; pullet nesting 374; eggs unferile, 412
Cockatoo picking its feathers, 443
Cocks, deficiency of, 300
Cocoa-nut fibre, 218; exhaustion of supply, 343; refuse, 462; as a mulch, 333, 371
Coleus Verschaffelti for bedding, 278
Coltsfoot, destroying, 370
Columbarian Society's Exhibition, 79
Compass, trimming, 39, 80
Compasses, beam, 259
Compost for flower garden, 455
Congress, Botanical, 397; M. De Candolle's address, 398
Conservatories—at Kew and Chatsworth, 53; management, 54; plants for back wall of, 85, 353; plants for piers and walls of, 229; climbera for, 481
Cork tree, transplanting, 11
Cork and South of Ireland Poultry Show, 38
Cevent Garden Market, 11, 52, 59, 71, 111, 121, 159, 169, 187, 205, 227, 247, 262, 277, 295, 316, 332, 353, 370, 386, 408, 424, 445, 461, 481; measures at, 72
Cramp in fowls, 20
Cream Cheese, 336
Creve Cœur—fowls, 334; chickens, 443
Crocus sparrow-eaten, 72
Cropping, out-door and double, 225
Crops of fowls swollen, 388
Croquet ground, top-dressing, 132
Crossing fowls, when taint ceases, 192
Crystal Palace—Bird Show, 155, 174; Spring Flower Show, 220; Show, 361; Rose Show, 474
Cuba, 440
Cucumbers—constructing pit for, 13; in hot-water pit, 73; plants decaying, 73; soil for, 94; in a frame, 151; leaves injured, 152; for exhibition, 206; culture, 220, 251, 293, 385, 423; culture and house, 257, 263, 346; leaves injured, 370; thick-ended, 378; bones for winter, 291; diseased, 425; roots diseased, 462; dying at ends, 462
Cucumis dudaim, 143
Cupressus Lawsoniana, 440
Currants, Black, wild, 367
Custard Apple, 370
Cuthus's show of spring flowers, 239
Cuttings—botted for, 112; removing leaves from, 229; propagating by, 262; frame for, 316

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 41.7°; and its night temperature 29.9°. The greatest heat was 57°, on the 3rd, 1869; and the lowest cold 4°, on the 2nd, 1854. The greatest fall of rain was 0.86 inch.

A HAPPY NEW YEAR!

It is with many persons a custom to watch out the year, to relinquish in a friendly way the departing guest, and to greet cheerily and trustfully the new comer.

Although I had experienced a rather fatiguing day, I was determined thus to act. Undeterred by the reiterated arguments and warnings of my better half, who remarked, "What folly! Why, you know you 'll be asleep in a few minutes! You are as tired now as you can be!" I waved her away, my determination was unalterable. I would hear the old year rung out, or at least sit up till the time when that ceremony takes place, and so I only replied—

"Ring out, wild bells, to the wild sky,
The flying cloud, the frosty light;
The year is dying in the night.
Ring out, wild bells, and let him die."

And yet, to tell the strict truth, it was useless waiting for our village bells to ring out, as we have but three, and one of those is cracked; so wisely we do not ring in the new year, fearing that if we commenced the operation we might frighten him away altogether.

Left to myself, the house was soon quiet. Silence and night are the times for visions. How many persons in company together have ever seen a ghost? The fact is that these supernatural beings agree with the proverb, "Two are company; three, none," and they prefer making their visits to single gentlemen and ladies—not necessarily bachelors and spinsters, but a state of single blessedness, whether of long or short duration, appears necessary to enable us mortals to make their personal acquaintance.

Determined to resist any attacks of "Nature's sweet restorer," I had ordered coffee, and indulged in a strong cup of the refreshing beverage; I soon was hard at work, pen in hand, indulging in some stave to be inflicted first on "our Editors," and, by their sanction, on the readers of "our Journal." My pen ran fast and furiously. I could hardly believe my eyes, but the hands of the clock marked 11.45 p.m.! Was it possible? Well, the pile of manuscript showed I had not been idle, and my watch agreeing as to time, I rested my head on my hand, intending to meditate away the remaining moments of the year. I was soon lost in a reverie. New friends, alas! too frequently usurp the place of the old; the rising deity is worshipped I would not, however, be so ungrateful to my expiring friend; he had been the bearer to me of many mercies, and as these rapidly flitted through my brain, I trust I felt grateful to the Giver of all good; A.D. 1865 would be in my diary a year of mercies and pleasant memory. And now, whether the weird influence of the near approach

of the first small hours of the new year, or the expiring moments of the old, or whether these were striving for the mastery I cannot determine, but visions appeared and vanished before my mental sight with great rapidity. Remember, I was not asleep! Mrs. "Y. B. A. Z." might have been certain I was; nay, she would have brought forward the closed eye and the heavy regular breathing as conclusive evidence of her view of the case; but every one knows how conducive to sound meditation is that closure of the lids, which separates us from the material world, and allows our thoughts free scope. It is, perhaps, often mistaken for sleep; but who, I ask, is the best judge—the person looking on the closed eye, or the unconscious person so absorbed in thought? Let common sense determine. As I have already remarked, I did not, although I might have felt disposed, intend to go to sleep—of course not! therefore Mrs. "Y. B. A. Z.'s" theory must go for what it is worth!

As I had been writing for "our Journal," it was natural that my meditations should be on the same subject. I reflected on the eagerness with which I hailed the weekly issue, not *weekly*, mind you, for none of us are disposed to think lightly of anything in which we ourselves sometimes bear a part, however insignificant. Besides, was it not *our* Journal? I seized the last Number, and scanned its contents, and I became identified with the various contributors, and was fairly, I presume, under some mesmeric influence. I was in a part of the country new to me, surrounded by busy workers, and I fancied myself metamorphosed into "DEVONSHIRE BLE-KEEPER," and I was dismal and desponding under a visitation of foul brood, but perseverance rendered my apary again flourishing and contented; yet as I looked at this longed-for result, I saw on the table before me a small bell-glass, hermetically sealed, containing a curious substance; it was labelled, "The last trace of foul brood. Lower, there it is." Then I was no longer the "DEVONSHIRE BLE-KEEPER," but "FILIX-POMINA," scrambling after some rare specimen of Fern high aloft, a treasure I had long coveted, to wit— Well, I do not doubt but that I could find some suitable Fern name that would do duty, but botanical names are a somewhat tender point with me, and I forbear. I have a painful recollection of losing caste in my younger days. Veronica heccalunga is one of the few botanical names that fastened itself on my memory. The name, alas! was only there, and in me it had no connection with any plant, yet being, as the old woman said of Mesopotamia, such a comforting word, it often served me for reply when appealed to for the name of any plant. Failing this reply, I generally coined some word, making it a *sine qua non* that it should contain four syllables. On one occasion, when out with several friends, who were aware of my penchant for Veronica, the question arose, What was the name of that little plant in the brook? I was referred to. It was a moment pregnant with my botanical fate! it was the tide in my history, which I failed to avail myself of. Had I but continued constant to Veronica I might ever after, maintaining a discreet and convenient silence, have passed for a botanical authority, perhaps even for a genius. *Miserabile dictum*, I coined a word,

instead of applying my stock name. Ah! the evening's reference to a botanical work, came like a "Withering" blast on my botanical knowledge; it proved that even my stock plant was unknown to me! Excuse me, then, if I forbore to hazard any Fern name, it was present, and I knew it; for was I not "FLUX-ROMINA?" I struggled on to grasp my trophy, but just as success appeared certain, the scene shifted, the rocks seemed divided into compartments, most of them tenanted by some living specimen. I was in a poultry show alone, "the monarch of all I surveyed;" in fact, I was Judge—a book of names and numbers in my hand, instead of the much-coveted Fern, which was "gone from my gaze." I paced up and down, settled the merits of the various rivals, gave in my decisions, and the public were admitted. Soon I found myself surrounded on all sides by malcontents, vainly endeavouring to answer a dozen at once. I begged to be allowed reference to my numbers, the list appeared different. I became confused, and was only recovered by a voice exclaiming, "That is not the Judge, but the gentleman who judges the Judge, and criticises birds and committee, that's 'WILSON'S RECTOR.'" I felt he was quite correct, I smiled, and passed through the crowd; and my list of numbers was the printed catalogue, with my remarks in pencil, for "our Journal." Referring again to my catalogue, a metamorphosis had occurred; it looked more like a petition, very numerously and, as the county paper would say, influentially signed; my identity with "our Chaplain" became very doubtful. Manifestly I was now a railway director, and the petition was that of poultry exhibitors, praying to be relieved in some degree from the expenses attendant on their journeys. Cogitating what reply to make, I was on the point of speaking, when, glancing at the petition, I found it to be the last Number of the 1865 series of "our Journal," and I seemed to be the proprietor! Ah! this was vastly too good to be true! I wonder it had not roused me. I feel certain that if Mrs. "Y. B. A. Z.'s" theory of sleep was correct, it must have done so! I turned over the pages, glanced at the long rows of advertisements, which seemed bent on crowding out the other portions of the work, and, hesitatingly, I asked myself, "Must we increase its size?" This is a step requiring great consideration. To alter the form of an old friend is sometimes to lose him altogether. The difficulty was great, but I felt that something must be done if they maintained the same rate of increase. In the height of my dilemma as to the settlement of this knotty point the strangest sensation overpowered me. Every one has heard of the Siamese twins, well, I felt in a measure like them; I was united to somebody, but, unlike the twins, we were intent on different portions of the same subject. Gradually I became sensible that my twin brother and I were "our Editors." Other editors usurp the editorial plural; we, from our duality, were entitled to it. Seated on our high official thrones in the dark, dingy, smoky 141, Fleet Street, we mused over the new-year Number, determined that out of our metropolitan darkness we would throw light and sunshine over the world. We reflected gratefully on the new friends of the past year, and then on our success. Suddenly we became aware of the presence of a large number of contributors outside our editorial sanctum, anxious to testify to us their kindly feeling and their unabated interest in our periodical. To me individually it seemed very pleasant to be introduced to the various characters. I noticed plainly "D., Dial," with new Rose catalogues of 1865 in his hand. Strangely enough, as his eye fell on some of the names, his hand moved, as if writing, and the names of various Roses were blotted out, and the stock seemed to be sold already. "RESISTO BACCHARI," again, with a present of Peaches and Strawberries; how produced now was the my toy, but then he makes adverse circumstances bend to his will; the last bunch of Roses, too, was in his hand. The thought presented itself, How will they flourish under this new regime? "FLUX-ROMINA," too, came back from Rome on purpose, "ALICE" and "FLUX-ROMINA" also; and the boxed cases showed that they would have something to say in 1866. Many others, too, in the floral department all seemed to say to us, "FORWARDS AND ONWARDS." As representatives of the other portions, there was "OUR CHAPLAIN," with his warm-hearted greeting, and catalogues innumerable of 1866 under his arm, and I wondered at the impertinence of such ante-printing; but then he is privileged; then Mr. HEWITT with a lot of notes supplementary of the "Standard of Excellence," and B. P. BARNY with remedies for all kinds of diseases, and "ECONOMY," "ORD" and "YOUNG COCHRAN," "BURNING," and positively an "IMPRISONED TURKEY," but with plumage quite uninjured, and looking quite contented and happy. On one side there was "DEVONSHIRE

"BEE-KEEPER" looking as though he had never had to do battle with foul brood, and the Scotch bee-keepers revelling in their heather, and then the alphabet seemed all sixes and sevens, A refused any longer to concert with B, but had singled out some distant member, and they were so closely united, they might always have been so. A similar fit had seized the other letters. Overpowered by this unexpected demonstration, we rose simultaneously, and expressed our gratitude at meeting so many of our friendly contributors, and assured them of our earnest endeavour to render "our Journal" worthy their support, adding that their warm-hearted kindly greeting would go far towards making the new year happy and prosperous. We closed with reciprocating their good wishes, we trusted that the new year would prove to each and all a Happy New Year. Scarcely had the words passed our lips, when we were conscious that some other person wished to enter, and our eye caught that of a stranger of unprepossessing appearance, who pushed forward and politely presented us with a parcel. Removing the envelope it contained an Apple, labelled "Apple of Discord." We replied he must have mistaken his destination, that our endeavours were exerted to increase and extend harmony and good feeling, our lives spent in sowing broadcast over the world the love of all God's creatures, and that we desired, that through the works of creation the love of human beings might be directed up to Nature's God, who was Himself the God of harmony, peace, and love; and lastly, that our hearts were set on making the new year a truly happy year to all, but especially to all our kind friends and contributors. We have just expressed these sentiments, we intend to stand or fall by them; we, therefore, assure you that in the pages of "our Journal," no such fruit will ever be discussed. Seeing his error, he was retiring, leaving, however, the objectionable offering on our desk; we, therefore, as gently as our excited feelings would permit tossed the Apple after him. As it fell to the ground, a loud explosion, which dispersed all our friends, proved how base were the intentions. The report recalled me to my own little world, and I found it was

"Midnight,
And the clock-wre striking the hour."

The Old Year had passed away, the New Year with all its hopes and anxieties was entering the threshold. My coffee-cup was no longer on the table, but in fragments at the foot of the opposite wall, and the marvel was, How did it get there? Moreover, on my foot-cap, where I had commenced my meditations, there was now a most curious hieroglyphic, which might have passed for the signature of some Chinese or Persian contributor; whilst the previous writing was shaky and uncertain, and I, who had figured in those few moments as the representative of so many distinguished persons, found that although thoroughly endorsing all "our Editors' kindly wishes for the New Year," yet I was neither our respected Editors, nor the lucky proprietors, but simply that unknown quantity—Y. B. A. Z.

REMOVING AND PLANTING FRUIT TREES.

To describe the system which I adopt, and the cause of my adopting it, it will be necessary for me to revert to the scenes of my early childhood, and to touch upon the Apple-tree nurseries in the neighbourhood of Chard, in Somersetshire. Two miles to the south-west of Chard, on the main road to Axminster and Honiton, is situated the pleasant little village called South Chard. In this village there lived a family named Dean, famed for the cultivation of young Apple trees. Here many acres of the Apples suitable for cider-making were grown, and the quantity of trees sold by this family every year to persons far and near, proved how well their trees were appreciated. The clean straight stem, the well-regulated head, and the mass of beautiful, clean, fibrous roots, added to the confidence reposed in the raisers, that the kinds were what they were represented to be, gained at once for them a ready sale. Samples of the trees were exhibited in the market towns in the first week in October, and through the planting season. It is now many years since I saw these neat and well-kept nurseries; but well do I remember when a boy, lingering near them to admire the luxuriant growth and symmetry of the trees, and the exact distance apart at which they were planted, for stand which way you would the trees appeared in rows as straight as an arrow.

In describing the mode of cultivating the Apple tree adopted by Messrs. Dean, I must be guided entirely by memory, for I have not seen the nurseries nor their kind-hearted proprietors since I was a boy, but the lesson I then learnt by watching the

operations in progress, when chance took me that way, have never been forgotten. They have been a never-failing guide to me ever since I have been capable of thinking for myself; and whenever anything in the varied practice of the garden in connection with fruit trees engaged my attention, what I saw when a boy comes fresh before my mind.

The sort of land which the Messrs. Dean selected for their new plantations was a piece of old pasture, which, I may remark, in that neighbourhood is deep, rich, and very favourable for the cultivation of the Apple. The land, after being well manured, was dug a good spit deep, turning the grass all to the bottom. The young stocks were then planted about 15 or 18 inches apart in the rows, and 3 feet between the rows. This operation was generally performed early in October, and the stocks would be well established by the following March, when they were grafted close to the ground. During the following season they would throw up strong shoots, and strong posts were then driven in at intervals up the row, stout strings fastened to them, and to these the young shoots were tied, so as to prevent their being injured by wind, &c. In the autumn after being pruned, a large quantity of furze was spread all over the ground, covering the young trees to a depth of 2 feet or more up their stems. They were then cut back to 6 feet 6 inches in height. At this height from the ground the heads were formed, the stem being kept clear of all shoots; and in two years from this time the trees were perfect models, and fit for the orchards. By this time, too, the furze had become completely decayed, and most of it was appropriated by the thousands of small fibrous roots which the tree had been induced by the furze to emit from its collar. The tendency of the tree to send its roots deep down into the soil was thus prevented; and the genial moisture kept on the surface by the furze, and the warmth of the atmosphere above, all had a tendency to attract the roots upwards. When the trees were taken up they presented a perfect mass of beautiful roots, not one strong tap root was there to be seen. This will illustrate the advantages to be gained by mulching fruit trees with furze.

In the removal and planting of trees of any kind, care must be taken—

1st, To keep at a proper distance from the tree when digging around it. If it is a large tree that has to be removed, it is necessary to dig a trench about 2 feet wide, and 2 feet deep, more or less, according to the depth of the roots, and about 4 feet from the bole of the tree all round. The soil should then be regularly but carefully worked out from amongst the roots with a fork, and the roots tied up as the operation is carried on. As the roots are placed out of the way the soil must be thrown out of the trench. This must be continued till the roots have all been secured, and enough soil taken away to allow of the tree being removed, but on no account should it be twisted about before the roots have all been properly loosened. If these have been carefully preserved from injury there is no necessity for removing a large quantity of soil with the tree; the attempt to do this often causes very serious injury, for the weight becomes unmanageable, and the tree is often put down after scuffling along with it a few yards, sometimes not very easily. By the time the tree reaches its destination most of the soil will have been shaken from the roots, and these will have been very much damaged, which is a loss, and a great drawback.

2nd, The proper time for removing fruit trees, such as Apples, Pears, Peaches, Plums, Nectarines, &c., when it can be done without injury to the crop of fruit which the trees may have on them at the time, is before the sap begins to recede. This will be the first week in October, or they may be removed in the third week of September, if the weather is not too dry at the time; and even if this should be case, if some green branches of any kind are stuck in and around the trees, and the syringe freely used about them two or three times daily, they will suffer no injury.

3rd, I now come to one of the most important points in connection with the planting of the tree. Never dig a deep hole to plant it in, but rather plant it on the surface after breaking this up with a spade. After the tree has been placed in the position it is to occupy, the roots should be carefully straightened out all round, and any that may have been injured should be shortened back with a sharp knife; some fine soil should be at hand, this should be sprinkled evenly amongst the roots so that all the small apertures may be well filled up, using plenty of water at the same time, and the tree should be frequently moved to and fro until the roots have become firmly imbedded in the soil. A bank should then be thrown up just at

the extremity of the roots, to keep the water from running away from the tree; this should be on a level with the collar, or if it is a little higher it will be no worse. Several potsful of water may then be thrown about the tree, and holes made from the surface down amongst the roots. The water will by these means settle the soil nicely about the roots; more fine soil and water should then be put round, and the water standing on the surface will soon show when all the vacant spaces about the roots are filled up. The tree should then be left, and after the next to be removed has undergone a similar process the water will have gradually soaked away through the soil, leaving the latter well settled about the roots. More soil should then be banked up around the tree, which must also be well secured to prevent its being blown about by high winds.

For securing large trees I generally drive four strong stakes into the ground, east, west, north, and south, and after they have been firmly driven in I fasten the trees to them; round the stem, however, must be put a good stout collar made of some soft material, such as an old guano bag, in order to prevent the ropes from injuring the bark. Some of the branches should also be cut out if the tree is large, so that the roots may not have too much work to do. If all go on well these will soon be at work, and the tree will draw sufficient nourishment from them to enable it to stand the winter without suffering any ill effects from its removal. If it is well mulched so that the frost cannot penetrate so deep as its roots, they will be active all through the winter. One of the great advantages to be gained by removing fruit trees in this way is, that there is no fear of sacrificing the crop of fruit. In the following year, if they are carefully managed, they will produce fruit nearly if not quite as fine as they would have done had they not been moved.

One of the great advantages gained by planting on the surface is this: The sun has more power on the roots; these consequently become well ripened, and the tree, instead of drawing up more sap than it can make use of at once, draws it gradually, and equally distributes it to its numerous branches, so that it performs its functions with greater regularity. The tree also grows less luxuriantly, and consequently matures both root and branch as it grows; all the small branches and spurs are covered with fruit-buds; and instead of the roots going down they will be spreading near the surface. When the tree is planted in a hole made for it to a depth of perhaps 2 feet or more (and in many cases the hole is made even deeper than that), a foot or more of good soil is probably put into the bottom of the hole; but this is the worst plan that could be adopted, because it encourages the roots downwards. The first roots that take hold of the good soil in the bottom of the hole soon become tap roots, then away they strike still further down into the clay, or whatever the bottom is composed of. These roots throw up sap faster than the tree can dispose of it: hence the long unripened shoots which must yearly be cut away, gradually hastening the tree to its decay. We see it year after year making rapid growth, but no fruit is produced. After a time the tree decays, and is replaced by another, which in the course of time follows in its wake.—J. WILLS.

FORCED RHUBARB ON CHRISTMAS-DAY.

HAVING observed some remarks made by Mr. Fish in your Journal, at page 508, respecting Rhubarb-forcing, I wish to state my experience in forcing this vegetable.

In the first place, then, I may say that I sent in two good dishes on the 22nd inst., and had some ready four or five days previous to that, about which time, I presume, Mr. Fish wrote his article, so that, I think, mine must have been ready a week before his. I have had plenty of it since. The roots, which are three or four years old, were transplanted into rich soil last March (they had been previously grown in poor soil), and were taken into the Mushroom-house on the 25th of November, the temperature being from 60° to 65°. Some light rich soil was put round them, and they were syringed daily, which caused them to commence growing at once.

I have formerly endeavoured to have Rhubarb at Christmas by introducing it into a temperature of 65°, afterwards gradually increasing the heat to 75° and 80°, but with somewhat indifferent success. I therefore conclude that Rhubarb can be accelerated with a greater degree of certainty with a uniform temperature of from 60° to 65° than by subjecting it to one 10° or 15° higher; indeed, I think that the temperature above recommended and darkness are two most essential points in Rhubarb

forcing. I beg to add that this communication is by no means intended as a disparagement of Mr. Fish, as his is by far too wise a head to learn anything from me; but I thought it might be useful to those who may experience a little difficulty in obtaining a dishon Christmas-day.—R. F., *Liverpool*.

HERBACEOUS CALCEOLARIA CULTURE.

In order to have fine plants to flower in May and June, the seed should be sown in July in the following manner:—Take a common seed-pan with plenty of holes in the bottom, fill the pan rather more than half full of drainage, and upon this place a thin layer of fresh moss, then fill up the remaining space with a compost of leaf-mould, leaf soil, a very little peat and sand, well mixed, but not sifted. Some of the roughest parts of the compost should be placed at the bottom over the drainage; 1½ inch of soil is quite depth enough for the seed. Cover the soil with a very thin layer of sand, give a good watering through a fine rose, and let the pan stand for two or three hours to drain; then sow the seed, taking great care to distribute it equally over the surface. Sometimes the seed is sown all in patches, and the young plants come up so thickly that they cannot succeed as they otherwise would.

After sowing the seed, press them in gently with a piece of slate or other smooth surface; then give the slightest possible covering of dry sand, set the pan aside, and give a very gentle bedewing either with a very fine rose or syringe. Select the coldest and most shady part of the garden; cover the pan with a piece of glass, and the whole with a large hand-glass. Keep the atmosphere of the hand-glass damp and cold by daily sprinklings all round the pan in dry hot weather; the soil in the pan rarely needs any water from the time the seed is sown till the seedlings begin to come up, providing all about the pan is kept damp and the sun totally excluded. It is usually about nine days before the young plants begin to show themselves, longer if the seed is more than one year old, and as soon as they are fairly up the piece of glass laid over the pan may be removed, but the hand-glass should remain as it is for a fortnight, after which time it should be tilted so as to admit plenty of air, and in a little time it may be taken off altogether, but, in case of heavy rain, it will be necessary to replace it to prevent the plants being washed out.

As soon as the seedlings can well be handled they should be pricked out, about 1½ inch apart, in pans prepared as for sowing the seed, only not using quite so much drainage. After this replace them in their old quarters, and sprinkle them every evening through a fine rose to encourage growth. When they have become nice little sturdy plants they should be potted off singly in well-drained pots, again placed out of doors, and kept there as long as the weather will permit. They should, however, be so placed that they can be covered from the heavy rains which sometimes occur in September and early in October; they will also be benefited by more light as the season declines.

When housed the plants should be placed as near the glass as possible in a cold airy situation, either in the greenhouse or cold pit. They can hardly be kept too cold, providing damp air can be dispelled and frost excluded. Keep down green fly by frequent fumigation, which, however, should be very cautiously done; fumigate slightly and often rather than strongly and seldom. I have been disgusted before now, after fumigation, at finding half the leaves looking as though they had been scalded by hot water. They will not bear the smoke so strong as the leaves of the generality of plants. Shift the plants as they require it, never allowing them to become too much pot-bound. I always shift just when the roots will keep the drainage from falling about when the plants are turned out of the pot. When growing fast, and in a healthy condition, they like a liberal supply of water, which should be clear rain water.

In the spring, from March till the end of April, the plants are best kept in a frame set upon cinder ashes; thus placed, kept free from green fly, and screened from easterly winds, they usually make rapid progress. In these months slightly shade from the mid-day sun, and give them a gentle sprinkling with the syringe at shutting-up time; in sunny weather they seem to glory in a little moisture, and in the morning they will be covered with little dew-drops, which always indicate health.

When about to throw up their flower stems they should be removed to the place where they are intended to bloom, taking

great care to keep down green fly, and paying attention to shading. If the plants are strong, which I presume them to be, it will be no slight task to tie them out properly—a task that always gives me great pleasure. The sticks should all be painted green, although I have been, and am now, obliged to use them unpainted. When the flower-stalks are rising a little very weak manure may be given twice a week, but withhold it while the plants are in bloom, at which time they should be kept well shaded, otherwise the flowers will soon drop, but if, on the contrary, due attention be paid to shading, these will last a long time. Allow all the air possible on all occasions when the thermometer rises to 40; they dislike fire heat.—CHARLES EDWARDS.

SOMETHING MORE ABOUT ROSES.

THE late Mr. Beaton was right in the main in preferring Roses on their own roots, and in supposing, for I do not recollect his having proved it, that the Manetti stock was a medium for getting them in that form. By comparing the facts furnished by contributors, and by actual observation in different parts of the country on the growth of Roses in different soils, I believe the truth, as far as yet ascertained, amounts to this:—That Roses flourish on their own roots in a greater variety of soils than in any other form; that they do best on the Manetti stock in light soils, where sands of later formations predominate; and that they do well on the Briar (*Rosa canina*), where the Briar is found to grow most luxuriantly in its wild state, as on stiff chalky land, and some clays. Assuming these data as approximating reality, we can readily account for the preference given by so many cultivators to Roses on their own roots, for the Manetti being selected by others, and for the disappointment frequently expressed by purchasers of Roses on the Briar, because these have been transplanted into soils less adapted to the stock than that from which it was taken before the Rose was budded on it. If "COUNTRY CURATE" is growing Roses in all these forms, he will, before long, certainly find out which will be the best suited to his situation, and had he stated what kind of soil he is growing them in it would have rendered his inquiry a little easier to discuss.

The readers of this Journal are already aware of my advocacy of the Manetti stock, a lengthy defence of it would, therefore, be a needless repetition. The soil here is very light and of good depth, and being on a slight eminence is naturally well drained, the subsoil is the green ferruginous sand found in connection with the chalk system. I have at present in the garden about one thousand Roses in all forms, budded, grafted, on Briars high and low, and on their own roots. As I have stated above, the soil is of the kind in which I have always found the Manetti stock preferred; hence, I soon discovered the evident superiority of that stock for propagation to any other method, and that, too, as a medium for getting Roses on their own roots. Roses planted out in a soil like mine on their own roots, are very long in becoming strong, and vigorous enough to withstand all the vicissitudes of the climate—not so with well-budded Manetti plants, in nine cases out of ten they make strong shoots the first year, and in the second the flowers are satisfactory.

The theory of "COUNTRY CURATE" appears feasible enough, and may be worth a trial. As the Manetti will bear moving at almost any time in the year, I should recommend an earlier month than November for removing the patch of bark which he believes would be instrumental in hastening the formation of roots at the junction of stock and bud. If the trial be made at the end of September, or the beginning of October, the chance of causing a development of roots in the same autumn would be as probable as in the succeeding spring and summer.

There is a greater distinction between grafted Manettis and budded ones than many people would at first be inclined to believe. My experience thus far shows that Manetti stocks grafted under glass with artificial heat, useful as the plan is for securing a rapid propagation of new varieties, have drawbacks when planted out of doors. In the first season they are very liable to mildew, make little growth, and produce few flowers, and it is not till the second or third year that they become useful plants. I have also found that they do not readily throw out rootlets at the point of union. With budded Manetti stocks the case is different, provided they are budded as low as possible and with the stock in the open ground. If

budded early in the season, a plant is formed at once which should be removed in the autumn; and planted in such a soil as mine, the bud should not be less than 4 inches below the surface. I think "COUNTRY CURATE" will find, that if he plant deeply enough roots will be formed much more rapidly than when the junction is too near the surface; care must, of course, be taken that the root of the stock is not buried in wet cold soil, which will be very likely to cause the death of the plant. If Manetti stocks are budded late in the season, it is better to leave the bud dormant all the winter. This is done by deferring till the following February or March the cutting off any of the stock into which the bud is inserted. In severe winters some casualties may occur in late budding.

In October last I examined the roots of about fifty of my oldest plants, now grown strong. In most of the budded plants of more than three years old, roots had been formed upon the stems, springing from the point of union and that part of the first shoot below the surface. In the grafted plants which were bought, plants of the then new kinds, and propagated under glass, no such roots had been formed, although it is quite probable that they will be produced. Not wishing to remove the plants, I cannot say whether the stocks of those plants which have roots formed from the Rose are dead or not. I cut off several stems with roots on them and transplanted them to another place. As "COUNTRY CURATE" would probably like to know what kinds have formed roots of their own, in the way above described, I subjoin the list:—Général Jacqueminot, Jules Margottin, Caroline de Sansal, Cecile de Chabrilant, Senateur Vaisse, Duc De Cazes, Princesse Mathilde, Triomphe d'Amiens, La Ville de St. Denis, Triomphe de Paris, Cardinal Patrizzi, Louise Odier, Eugène Appert, François Arago, Empereur de Maroc, and Louise Carique.—ADOLPHUS H. KENT, *Blechningley, Redhill, Surrey.*

POTATOES.

I AM obliged to "UPWARDS AND ONWARDS" for his article at page 485. Apples and Potatoes are the most valuable of fruits and vegetables, because they can be cooked in more ways than any other.

As regards Potatoes, with me a dinner cannot be excellent without a good mealy Potato. The Potato lists will soon be as burdened with sorts as the Rose catalogues. Of course each new sort is said to be the best early, mid-season, or late Potato known. The difficulty is selection. Moreover, much depends on the taste of a person, the soil, culture, and seasons. As regards resistance of, or escape from the Potato disease, I do not believe that any sort can be said to be thoroughly defiant. The earliest ripeners are as a class the most defiant. I believe that the disease has outwitted everybody; it certainly has upset all my calculations. I have known sorts much stricken one year give the soundest Potatoes the next year, and *vice versa*. Till we find out the nature of the disease we shall never perhaps find the cure or prevention. Digging Potatoes before they are ripe is a great folly; you will lose just as many by it, and you will spoil what otherwise would have been good. They will be watery or waxy, the latter is to my taste the more offensive.

I must here observe there is but one way to cook and serve up Potatoes—namely, to steam them, and send them up in their jackets. When they are "done" the steam must not be stopped down upon them, or they will be soddened. Out of the number of professed cooks how few can cook a Potato well! how few can roast a chicken or boil a leg of mutton as it ought to be done! Give me a duck or chicken roasted by a farmhouse cook; the maid knows nothing of "made" dishes, and hence she attends to and properly bastes these great luxuries.

Let me, however, turn to selection. Mr. Rivers's ideas of selection are that the Royal Ashleaf is the best to begin with, the Lapstones to go on with, and the Flukes to finish with. If I were to select a few only I would select the Royal Ashleaf to begin with, Fortyfolds, and an admirable Kidney Potato sent here by a Yorkshire friend, said to be raised from the Ashleaf and Lapstone, to go on with, and Salmon Kidneys to end with. The last are the best latest Potatoes that I have ever eaten; they require high cultivation, and prefer strong land. I fear that people estimate Potatoes by size and crop rather than quality and crop. What is the use of the crop if the quality is bad? The *qualitas vocis* means a fine name, the *qualitas rei* means a good thing. In how many instances have we been beguiled by the *qualitas vocis*! Be guided rather by the nature

of things than by their names. If a commodity is good I care not whether it be called Noblesse or Stump the World. The former is aristocratic, the latter democratic, or rather mundane.

The following are also first quality Potatoes:—Brookfruits, Early Mans, or Mauns, Dalmaboys, Flukes, Prizetake, Red Kidneys, and Silver Skins; the last are the nicest looking of all the Kidneys. These are good Potatoes, and good croppers:—Mona's Pride, Early Handsworth, Scotch Rocks, called here also Scotch Downs.

Taking this season up to the present time I have not had anything, for crop and quality, equal to the seedling Kidney raised from the Ashleaf and Lapstone. Its formation is strictly "renal."

As regards planting, I think Kidney Potatoes, especially those that have mole's eyes, should be planted shallow, and should not be planted till the eyes have started. They should not be cut, or cut very much. I think that in dry seasons if Potatoes were watered they would ripen earlier, and be safer from the disease. I some years ago watered my Royal Ashleafs just as I water my Roses, and they had not one diseased tuber. Potatoes keep better, and are better flavoured, when dug after rain.—W. F. RADCLIFFE, *Tarrant Rushton.*

GARDENERS' WAGES.

THE education of gardeners is a question that has been freely discussed, and its importance I must admit. Education is very necessary in order that the employed may give satisfaction to the employer; for what a great pleasure it must be for a lady or gentleman to walk through the plant-houses accompanied by an intelligent gardener who can give a descriptive account of each plant that may be noticed. Yet this is expected from a class of men worse paid than many labourers. Take for instance one of hundreds of cases. A lad wishes to become a gardener; the first consideration, as a matter of course, is to find him a place in a first-class establishment, which can generally be managed by paying a premium, say £10, more or less at times, to the head gardener, the lad receiving 8s. or 10s. per week for three, four, or five years. His duties for the first twelve months will be to attend to the fires, wash pots, and occasionally clean plants in the houses. From that he gradually ascends the ladder step by step, by being called to the potting-bench, tying plants, and assisting the foreman in the ventilation of the several houses. I will suppose his age now to be twenty. After serving five years he seeks and obtains a situation as under-foreman, at the advanced rate of 15s. per week. This situation he holds for a like time, taking notes of everything of importance carried on, taxing his memory with the names of thousands of plants, their distinct treatment, &c. From this he obtains a foreman's place as a finish off, at 18s. per week. He holds this until he is nearly thirty years of age, and often till later in life, before he can succeed in obtaining a head gardener's place. Many gentlemen object to engage a gardener who has not had the responsible charge of a place previously. I need not mention, that during the whole of the sixteen years passed, he has been studying the practical and theoretical branches of gardening, and out of his scanty pittance he must deny himself almost the necessaries of life to purchase books to gain the requisite knowledge of his profession. Should he after all these years succeed in obtaining a situation as head gardener, it will depend on his being free from incumbrance. At the rate of 30s. per week he may think himself at the top of the tree as regards wages.

Now, I ask your opinion, Are gardeners sufficiently remunerated? They are expected to know a portion of many branches of science, and they work hard all through the sunny part of their lifetime, both in mind and body, making old men of themselves almost before they are young ones. There are very few that have had much to do under glass, who do not know something about rheumatism, brought on by working sometimes in a temperature of from 70° to 80° for hours, and then turning out to cover up the frames, or something of that sort, with the thermometer registering 30°. Gardeners have a great many years of uphill work before they can acquire anything like a general knowledge of their profession. Then there is the responsibility and consequent anxiety day and even night, that is, should they have the superintendence of much glass. Many a gardener, I am sure, could bear testimony that during the forcing season, what with over-anxiety and fear lest anything should go wrong, a sleepless night often falls to his lot. The best of us are liable to failures sometimes, with

no allowance made for them. There is, also, a tendency on the part of some gentlemen to dictate to the gardener, and require him to do things in direct opposition to his views, and they will not listen to any objection which he may raise, or take any of the responsibility from him.

I trust that I may live to see the day when gardeners as a class will be better remunerated, their acquisitions appreciated, and their cottages more comfortably built.—W. E. J.

The most of the matters to which you allude have already received a good deal of attention in our columns. Much of the hardships of which you complain would be chiefly of use, if they could be brought under the notice of those young lads and youths intending to be gardeners. Then, if influenced by these hardships, there should be fewer aspirants after gardening, the very scarcity would insure better remuneration for those who are well qualified, from having passed through a series of regular instruction. Now, any one who can dig and mow may call himself a gardener, and such men offer their services at such a low figure as to keep down the general run of wages, and gentlemen and ladies are slow to find out the difference between a good workman and a man of science and education. We have frequently stated, that gardening, even now, chiefly offers an inducement to the sons of labourers and humble mechanics, who, by perseverance, self-denial, and self-culture, may thus rise themselves in the social scale. It holds out no inducement to the intelligent well-to-do middle classes, unless they depend on the poetry and romance of the employment as a good part of their remuneration for hard work with head and hands. We think it is well this should be clearly understood. Employers of gardeners will ever do as they like. They will give better wages when they cannot obtain cheaper gardeners. They will give higher wages, and require higher qualifications, when they find, as many are now doing, that one man well paid will be more economical for them than another man underpaid.

We will now glance at a few complaints, and but glance. First, There is no necessity for a five years' apprenticeship, and even so many years afterwards, before taking any kind of a place. A man will learn more, even in a small place, superintending everything, than he is likely to do as an under gardener with the charge of one department. Second, We showed lately that the wages of under gardeners are not so much inferior to those of mechanics, when constant employment, and the hope of bettering their position are taken into account. Third, The custom of gentlemen wishing to have a man who has been in a situation before, is not confined to gardening; it holds good as to all positions of trust and responsibility; but it should show the importance of getting into a situation early, though a small one, and thus obtaining a family character. Fourth, We know all about the self-denial, and it is often hard, and we sympathise with it all, and from what we see and hear, things are looking better than they did; but we must expect this self-denial in one shape or other. Make everything comfortable and you will have still a greater number attracted to enjoy the comfort, and thus, again, the supply will exceed the demand. Where all the young men even now go to, that are sent out from some places, as if they were struck like batches of bedding stuff, passes our comprehension. We do know that a great many leave gardening to look after itself, and try something else. Hold out greater inducements, and there will be still more applicants. Here is where the great dilemma and difficulty are to be found, and which stand in the way of the better remuneration which gardeners so much desire, and which will be obtained, as already hinted, when good gardeners are more appreciated. Fifth, There can be no doubt that working much in houses is unhealthy; but this could be much obviated if young men would clothe themselves sufficiently before rushing from a high temperature into a low one. Sixth, As to employers dictating to their gardeners, and having things done their own way, with that we cannot intermeddle. An old nurseryman told a gardener when a young man, "If an employer tells you to plant the branches of a tree in the ground and the roots in the air, do it. Calmly tell him you think it won't answer; but if he insists carry out his plans." Every employer has a right to decide how he will be served. There is a foolish soreness on this point amongst gardeners. They feel annoyed when they cannot do just as they like. When a plan is proposed which you feel sure will not answer, state your objections respectfully, but give the plan every justice; then, however, the employer must take the responsibility of failure or success. This is a delicate point, but a little firmness and integrity in carrying out the proposed plan, will generally be

sufficient to absolve the gardener if the plan should fail. Responsibility can only be associated with the power to regulate. Lastly, The difficulty that a gardener with a large family has in obtaining a good place, is both true and sad; but the difficulty is not so great as it was. Gentlemen are beginning to see that there is as much necessity for a gardener having a house suited to a family, as any, nay more than any other outdoor servant. They are also finding out that men with families are less given to change. We hope the word incumbrance will cease to be associated with "the olive plants" that gather round the gardener's table. Every addition is generally a fresh pledge to renewed exertion and industry. Gardeners, in fact, ought always to be out-door servants. As well give a man the punishment of Tantalus at once, as place a spruce young fellow in a housekeeper's room with a number of well-dressed ladies' maids and other female servants, and give him clearly to understand that no married gardener will ever be kept there.

THE above answer to "W. E. J." was in print when we received a long letter from "AN UNDER GARDENER" on low wages, miserable lodgings, &c., very well written, but to the most of which, we are sorry to say, the above is all the answer we can give. We will note the following in addition:—

First, The alleged disfavour with which such matters are received. The best answer to such an allegation is what we and others have been permitted to write in these pages for years, and we might even refer to what is said of bothies in the Christmas Number, and, above all, to what is so well said by that gardener's friend, and, we believe, every man's well-wisher, our worthy coadjutor the "WILTSHIRE RECTOR." At the same time nothing would be gained by a more frequent repetition of the same complaints.

Secondly, we are quite as glad as "AN UNDER GARDENER" can be of the rise of wages for the gardeners employed in the London nurseries, as, unfortunately, the low wages there acted as a sort of guide for the wages given to under gardeners in the country, a trifle more per week, and lodging, being too often deemed amply sufficient. This is particularly pleasing just now when everything, except bread, is so high-priced.

It would be out of place to enter into the consideration of the whole system of young gardeners being temporarily employed in a nursery. We may, however, let out the secret that, but for patronage and pleasing patrons, the system of employing young men in nurseries for short periods, even at low wages, is too often a loss to the nurseryman—so much so, that in some of our large nurseries a young gardener cannot obtain admission except as a great favour to some large customer, and some of the greatest of the London nurserymen have told us that it would suit them better to have regular good workmen, acquainted with their work, at good wages, as, by the time the young gardener was becoming useful, he was off to a place, and the constant changing, even with good foremen, was always a source of trouble. Looked at in this light, the nurserymen were less to be blamed for low wages when the nursery was merely considered a sort of house of refuge.

Thirdly, As to head gardeners being chiefly to blame for low wages and miserable lodging-places, we fear that "AN UNDER GARDENER" will not be convinced to the contrary until he finds, when a master gardener, that his representations will be less effectual than he now imagines they would be. No doubt there are head gardeners who, if pretty comfortable themselves, are very careless about the comforts of those beneath them; but there are many others who leave no stone unturned in order to forward the interests of all with whom they are connected, and many often do much with wealthy kind-hearted employers. But there are many others, to our knowledge, who are equally anxious to promote the comfort of their men, and have missed no opportunity of doing so by their timely representations, and yet have done all in vain. Is it to be wondered at that a lady or gentleman who will part with a gardener who pleases and suits in every way for the sake of five or ten pounds a-year, will refuse to give an under gardener a shilling or two extra per week? We can recollect of many instances in which gardeners, by representing they could not find an under gardener for a less sum, have been allowed to give that sum to one or two, but then they had to take labourers for lower wages instead of young gardeners, so that the labour account should not be raised. On the whole, a head gardener may often do much; but, on the other hand, however much he may feel, and however much he may try, he will find himself eribbed and confined wherever a greater expenditure is

involved. Kind-hearted employers there will always be, and who must have people comfortable about them; but there are plenty of others who, provided they can obtain what they want, will obtain that in the most economical manner, and very regardless of the circumstances of those who contribute to their comforts. We have hopes in the ever-increasing numbers of the truly beneficent as well as benevolent, but our chief hopes are in the lessening of the number of those who take to gardening as a trade or profession, and the more thorough grounding of these in the practice and science of their art. Meanwhile, we would wish to impress on intending pupils, and the parents of these pupils, that future success must be looked for in general through processes of self-denial.—R. F.]

MR. SYMONS' RECORD OF BRITISH RAINFALL.

It is well known to all who take an interest in meteorological matters, that Mr. Symons, of Camden Town, London, has for some years published in a tabular form a statement of the rainfall, as furnished him by correspondents from all parts of the kingdom; nevertheless, there may be some who have not heard of such a record, and have yet kept a register of the amount of rain which has fallen in their district. Should there be any such, they will do a service to the public by furnishing Mr. Symons with the rainfall of the past year as soon as convenient. Mr. Symons has invited such contributions through the London newspapers, and also through many provincial ones, giving the names of those observers who have hitherto furnished him with the desired information, and their respective districts.

Although the number of stations in the United Kingdom at which the rainfall is observed is now upwards of one thousand, yet there is still room for more, and Mr. Symons solicits an increase. The mode of keeping such registers is much simplified, as compared with what it was many years ago, and the expense of the apparatus has been reduced, so that I believe a very good rain-gauge can now be had for 10s. 6d., and in some cases for less than that. Mr. Symons' pamphlet gives some useful information on important meteorological events, and tables comparing the rainfall of one season with that of others are made out in an intelligible form. One thing, however, he has wisely refrained from, and that is, making predictions as to the weather. Some may, perhaps, ask, What then is the use of meteorological observations, if they are not to enable us to form some idea of coming events? To such I may say, What is the use of historical or chronological records of any kind, but to transmit to posterity what the past has been? Besides, records of rainfall in different districts afford an interesting study on the causes which contribute to such a result. Some districts amongst the Cumberland hills are found to receive more than six times as much rain as the general average of the kingdom, and it is quite possible, and, in fact, very likely, that the wettest point has not yet been favoured with a rain-gauge, or its rainfall recorded. Now, however, that men of science are turning their attention to the matter, I trust that these "out-of-the-way places," will be duly represented. Mr. Symons also invites those living near to others who already contribute reports, to send their registry likewise. Mr. Symons' address is 136, Camden Road, London, N., and printed forms for entry will be supplied by him when necessary.

I imagine that when the returns of rainfall for the kingdom are made out for this year, greater differences than usual will be found between the returns of certain districts when compared with others. On the whole, however, I think it will be admitted that the season has been a fine one, and the mildness of the autumn remarkable. Not many yards from where I now write, Nasturtiums are in flower, and quite unprotected; certainly they suffered a little from some frosts in the middle of November, and the continued dull weather has deprived them of that luxuriance which they exhibited in September and October; still they are green and fresh, and nothing in the garden is more susceptible of frost. Geraniums which have not been taken up are fresh also; but so they were up to the 17th of December, 1860; and although we are now a few days past the time when frost commenced in that memorable year, I can hazard no opinion as to the likelihood in the present winter of another such frost as that which occurred in 1860. Leaving that to the weather prophets we must content ourselves with recording the past, and although other phenomena than the amount of rainfall may be registered by those who

carry their researches further into meteorological matters, Mr. Symons only requires the monthly rainfall and number of days on which rain fell, and those who have the means of supplying such information will be doubly rewarded by the knowledge that they have contributed to a subject which is fast becoming one of national importance, and one from which they as well as others will reap the benefit.—J. Robson.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE December Meeting of this Society was held on the 4th ult.—The President, F. Pascoe, Esq., F.L.S., &c., in the chair. A very interesting collection of insects made in British Burma, by Lieut. Beauva, was exhibited; amongst which were many fine species of Euphea, and some new Hesperidae, also some rare and new Coleoptera, including a remarkable Tortoise Beetle of the genus Prioptera. Another collection, chiefly of Butterflies and Moths, in a very perfect state of preservation, made in the neighbourhood of Santa Martha, in Venezuela, by the late Mr. Bouchard, was also exhibited by Mr. S. Stevens. The excellent manner in which these specimens had been captured and preserved caused additional regret at the untimely decease of Mr. Bouchard. A mutilated specimen of the rare *Goliathus Drurii*, Westwood, being the only insect saved by M. Du Chailu, in his hasty retreat from the interior of Western Tropical Africa, and brought home in his waistcoat pocket, was also exhibited by Mr. Stevens.

Mr. Stanton exhibited some remarkably dark brown varieties of the common Moth, *Tinea cloacella*, reared from larvae found feeding under the bark of dead Birch trees at Llangollen, by Mr. Gregson.

Mr. F. Smith exhibited specimens of the Sawfly, *Croesus septentrionalis*, which he had found in the larva state on the 20th of August last. They had spun up in their cocoons in four or five days, and the perfect insects appeared a month later, thus varying from the ordinary habit of the family of lying unchanged within the cocoon during the whole of the winter. Mr. McLachlan, however, suggested that it was possible that there were two broods in the year, as he had taken the perfect insect at Loch Ramoch, in June. Mr. Smith also exhibited some specimens of the "Bugon," a large greasy-bodied species of Moth belonging to the genus *Agrotis*, which is eaten by the aborigines of New Holland in considerable numbers, and which had been forwarded by Mr. George Bennett, author of "Wanderings in New South Wales," to Dr. Gray, of the British Museum.

Some conversation took place as to the noises asserted to be made by the Death Watch, *Atropis pulsatorius*, the general opinion being that the common impression as to their origin was erroneous.

Mr. McLachlan read a memoir on the varieties of *Stirpa sacarina*, recently reared in this country, with observations on the causes and extent of the different variations to which the species of Lepidopterous insects in this country are subject.

Professor Westwood read descriptions of some new species of Longicorn Beetles belonging to the genus *Cantharocnemis*, but forming different sub-genera, and for which he proposed a series of uniform sub-generic names, in order to avoid the inconvenience resulting from the modern system of division, in which almost every species was raised to a distinct generic rank.

The Rev. J. Greene exhibited specimens of the newly-described British Moth, *Acidalia mancinella*.

Some further notes on the Euprestidae of New Holland, by Mr. C. A. Wilson, of Adelaide, were also read; likewise the description of a new species of Papilio, from one of the small islands of the Pacific Ocean, by Mr. G. Sempér, of Altona.

A fine series of drawings of the insects of North America, destructive to the Cotton, Orange, Lime, Potato, &c., intended for publication, was exhibited by Mr. Moore.

TODMORDEN BOTANICAL SOCIETY, December 4th.—On the table were the new and beautiful *Pteris serrulata cristata*; also *Scelopendrium vulgare polycausis angustum*, and *S. vulgare Malecomsoni*, the latter a splendid form, something like a gigantic *cristatum*, only that the fronds are of normal length and width from base to apex. A communication was read from Mr. T. Pritchard, of Erynyffynnon, North Wales, announcing his discovery near that place of the rare *Asplenium trichomanes incisum triangulare* (M), as well as several other rare Ferns, small specimens of some of which were laid before the meeting. Amongst them we observed a very beautiful form of the Lady Fern, belonging to the plumosum group.

HOUSE SEWAGE.

AN answer to correspondents on the above subject in your Journal of the 5th ult. rather surprised me. I have a cemented cesspool into which the waterclosets and sinks of three houses are drained; within a couple of yards I have a simple filter thus:—Two tar-barrels are sunk vertically in the ground, the upper one having both ends removed, and the lower one having a bottom pierced with holes; a layer of cinders weighted with a perforated slate, a drain underneath to connect with the cess-

pool, and a small pump complete the filter. The liquid has been liberally used to the fruit trees, Currants, young hedges, &c., by myself and neighbours during the past two summers, and we think with good effect, particularly to the Pears and Apples. The soil is light, rather sandy, resting on red sandstone, and during the late droughts I consider that the fruit was not only saved, but increased in size by the frequent application of the filtered sewage.

The gardens have only been formed three years. The trees in mine are trained as espaliers, and have borne much better crops than the standards in my neighbours' gardens, although the trees were all planted at the same time. I pinch in the espaliers very closely.

I think it would be a great boon to many of your readers if you or some of your contributors would discuss this subject. In how many cases in the country the house sewage runs to waste in an open ditch, or poisons the ground around the cess-pools, whilst every particle of manure has to be brought from a distance! Is there not any filtering medium that would take up the valuable products? Peat charcoal I would try, but where is it to be had? Soil will not allow the liquid to percolate quickly enough. Quicklime clears the liquid, but has no effect on the smell, and I am told that the deposit is spoiled as a manure. Sulphuric acid destroys the smell, and I believe the product is valuable, but would not the expense be great?—N. I. B.

[We not only have gone into the consideration of house sewage as a fertiliser very fully, but have collected what we wrote on that and other fertilisers into a book, "Manures, or Muck for the Many," which you can have free by post from our office for four postage stamps. What we said at page 469 had reference to the inquirer's particular case.

The flowers were too faded to be recognised; but under the best of circumstances, unless a Chrysanthemum is very remarkable, it would be very difficult to recognise it from a single flower, the varieties are so very numerous.]

A LARGE VINE.

On the seacoast, midway between Tyre and Sidon, is a very ancient Mulberry garden, surrounded by some enormous Olive trees, whose hollow trunks attest their great antiquity. By the garden side stands a cool fountain, fed by one of the mountain streams, so welcome to the traveller for his noontide rest when travelling through that thirsty land. After resting awhile at this pleasant spot, we rambled through the garden of Mulberry trees, partly for the sake of taking the fruit, but more with the intent of learning something about the rearing of silkworms, which was there in full operation. Whilst admiring the great size of the fine old Mulberry trees, I happened to notice the bark of a tree which appeared so Vine-like in its

character that I stopped to examine it, and, to my surprise, found that it was really a Vine of most enormous dimensions; it rose by two main stems, and fairly rested upon six or eight of the large Mulberry trees around. I measured the two stems a few inches above the ground; the larger one was 50 1/2 inches in circumference, the smaller 40 inches. I endeavoured to trace out the area covered by its branches, but could not obtain an exact measurement, for the branches had rambled most irregularly. It had a splendid crop of very large bunches of Grapes then, but in an early stage of growth, and I was told that it is a black variety. My impression is that it is one of the largest Vines in the world, and it would well repay a visit to "Ein-el-Kanterah," for that is the name of the spot, if it be sought for by any of your readers, whose rambling propensities may carry them along that seashore.—W. WASELYN.

PLANTING A CIRCULAR BED.

I HAVE a circular bed 11 feet in diameter, which I meditate planting next year as follows; but should like your opinion as to its worth, and also to guide me in the planting of the same as to the proper distance apart in the rows, as well as plant from plant in the rows:—

- 1.—Variegated Arabis.
- 2.—Variegated Sage.
- 3.—Variegated Euphorbia.
- 4.—Iresine Herbstii.
- 5.—Centaura candidissima, with three plants of Perilla in the centre.

As you will at once see it is meant for a bed of foliage. Would *Dactylis glomerata variegata* be better in No. 3?—SEASERT.

[We do not think your arrangement would look well. Having the three variegated plants together is bad taste. Had we a similar bed to plant, and if the position is a sheltered one, we should arrange the planting as follows, beginning from the centre:—

- 1.—Three good plants of *Canna discolor*; these would occupy about 2 feet.
- 2.—2 feet of *Cineraria maritima*.
- 3.—Ditto *Amaranthus melancholicus ruber*.
- 4.—Ditto *Centaura candidissima*.
- 5.—Ditto *Iresine Herbstii*.
- 6.—1 foot of *Cerastium Biebersteinii*.

The plants may be about 9 inches apart each way, taking care to plant them alternately, and putting the tallest plants towards the centre, and at the same time keep each circle to its proper width. The *Cerastium* should be planted rather closer than the others; from 4 to 6 inches apart would be a good distance for it. If the bed is on grass the above arrangement would look well. We have to apologise for accidentally overlooking this query and answer.]

FLOWER GARDEN PLAN.

THE enclosed set of beds occupy the top of a terrace about 40 feet wide, and are principally seen from another terrace about 5 feet above it. Two-thirds of the beds I laid out last

winter; the remainder, or from figures 7 and 6 to the right, I have just completed, and intend planting them as marked, but should feel much obliged for your opinion before that time

- | | | |
|--|--|---|
| <p>1 1. Centre of bed, <i>Heliotropes</i>; next a row of <i>Perilla</i>; then another of <i>Prince of Orange Calceolara</i>, the whole edged with <i>Bijou Geranium</i>.</p> | <p>2 2 2. <i>Christine Geranium</i>.
3 3. <i>Blue Lobelia</i> (speciosa), edged with <i>Lady Plymouth Geranium</i>.
4 4 8 8. <i>Purple King Verbena</i>.</p> | <p>5 5 9 9. <i>Aurea floribunda Calceolar</i>
6 6. <i>Tom Thumb Geranium</i>
7 7. <i>Manglesh Geranium</i>.</p> |
|--|--|---|

comes. I may mention that our soil is light, and that we are exposed to most, or all the storms and sun that there may be, so that the bedding plants generally do not grow tall but bloom most profusely.—R. D. T.

[According to the system of planting we could not improve

what you propose, and we have no doubt that it will look well. In another season we should be tempted to make your centre panelling row the centre, and then make the two sides the exact counterpart of each other. Your planting will look very well. We presume the plan is on gravel.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the weather continues much the same, the operations recommended to be performed in the past month should be proceeded with. *Cauliflowers*, if the autumn sowing failed, it will be advisable to sow in a box, which may be placed in a forcing-house, and when the plants are of sufficient size prick them out in a frame on a slight hotbed. *Celery*, trenches should now be dug out, so that they may receive the benefit of frost; in spring *Cauliflowers* may be planted in them, and dwarf Peas or Lettuce between, and these crops will be off by the time the trenches are wanted. *Cucumbers*, a seed-bed should now be made to raise young plants for the hotbeds, a one-light box is generally of sufficient size for this purpose; after the bed is made, and the heat is up, the dung should be forked up every other morning to the depth of a foot, until the burning heat has subsided. *Dwarf Kidney Beans*, earth-up as they advance in growth, never allow them to grow to too great a height before this is done; water them before earthing-up if they are at all dry. *Potatoes*, if young ones are wanted very early, some Early Frame, or any of its varieties, may be planted in a slight hotbed; if it is not convenient to plant them immediately, they may be laid in a forcing-house till they begin to shoot. *Radishes*, a second crop may now be sown in a similar situation to the last—that is, on a slight hotbed. Dung should now be prepared for forcing the various culinary vegetables which are required early; a considerable quantity of leaves may be used with it.

FRUIT GARDEN.

The work of trenching, draining, preparing borders for fruit trees, pruning, nailing, and dressing the ground may be proceeded with. Fruit trees may be removed and planted, but take care to keep the frost from the roots of newly-planted trees.

FLOWER GARDEN.

The absence of frost from the ground has permitted of a variety of work in this department being carried on. Borders not cleaned and dressed should at once be finished. Recently-removed plants should be protected. In the pinetum a little protection may be afforded to Pines of doubtful hardiness. We repeat these instructions, assuming that the weather has cheated some of us into forgetfulness of winter, whose approach is unusually delayed. We have still *Verbenas* in flower, and *Pelargoniums* uninjured in the open ground. *Dahlia* roots should be occasionally examined in order to counteract the effects of damp, &c. Where a quantity of young plants is required it will be requisite to put the roots to work by forcing them in a gentle hotbed or pit. Abundance of air is necessary to *Carnations* and *Picotees* in frames; for when kept in a confined atmosphere mildew is certain to be engendered. *Pansies*, which during the past fine weather have begun to move, should be carefully protected in the event of severe weather, as they will be much more susceptible of injury. Carefully exclude frost from the beds of *Tulips*. Those who have not obtained the necessary number of *Ranunculuses* to make up their beds ought to do so without delay, as the period of planting, the middle of February, will soon be here. If the beds have not been already formed, perhaps the simplest and best way is to excavate the soil 2 feet deep, put in 6 inches of decayed cowdung, covering this with maiden turfy loam to the depth of 12 inches or more, the remaining 6 inches to be equal parts loam, leaf soil, and sand thoroughly incorporated.

GREENHOUSE AND CONSERVATORY.

About 40° is a good temperature for the conservatory, when not attached to sitting-rooms, and used only for the purpose of wintering large specimens without plants in blossom; but where a supply of stove plants in bloom is constantly kept up from a forcing-pit, which is essentially necessary to every good conservatory in winter, the heat most suitable is 45° by night, raising it to 55° in the day. *Cinerarias*, which are great ornaments in this house in winter, are thirsty plants, and should be well attended to with water. They are also liable to the attacks of insects, and unless they are looked after they will soon establish these among other plants. *Chinese Primroses* are also very ornamental here; although they grow well near the glass, they do best in shaded places. With regard to soil, two parts rough leaf mould, and one of well-decayed cowdung, with a little sand, suits them best, and in this they like plenty of moisture. *Camellias* will now be swelling their buds. Neglect in supplying water must be avoided, and attention should be given so that it is applied in proportion to the

activity of the growth of the plants. This remark applies equally to other plants. Remove flowers as soon as they become shabby. Stove plants will take no injury for a few days in this temperature, but hardwooded greenhouse plants, such as *Heaths*, should not remain more than a few days at a time in such a temperature. Prune, train, and clean the creepers on the rafters. The *Pelargoniums* intended for blooming in May, if not shifted already, must be removed into their blooming-pots immediately, using a free open soil. Late-blooming specimens must now be stopped, preparatory to being potted in the end of February, and young stock must be encouraged, so as to make the plants strong and healthy. Herbaceous *Calceolarias* will grow very rapidly for the next three months, and, therefore, must be encouraged and kept clean. Fumigate slightly once a-week or ten days, but be very cautious, or you will injure the foliage. Water when necessary, but not over the foliage.

STOVE.

Here the night temperature must not exceed 60°, and if it fall to 50° in severe weather, no harm will be done. Keep the atmosphere rather moist, especially if the weather is bright, and remove such plants as are inclined to start to the warmest part of the house. Some plants, such as *Stephanotis*, *Allamandas*, *Manettias*, *Dipladenias*, &c., may be pruned, trained, and started, if by a gentle bottom heat all the better, but those plants wanted for late blooming must be kept back for the present. Some persons keep their stove plants now and for the next six weeks quite at rest, and in that state a temperature of 55° is quite enough for them in cold weather. No more water is given at the roots than will keep the leaves from flagging. A high temperature and dry atmosphere are much more injurious to stove plants than any cold they can suffer in a temperature above 45°. *Orchids* should now be kept as cool and dry as they can bear for about six weeks, and in spring increase the heat as the season advances, but still withhold water till early in summer, and then give it only when the buds are ready to start. Young *Stanhopeas* are more difficult to flower than established plants, because they are more susceptible of changes of temperature and moisture. From this time to the beginning of May give as little water at the roots as is consistent with the health of the plants, and up to the middle of February 55° is the proper temperature. The atmosphere should not be drier than that for a collection of stove plants; therefore, where two houses do not exist, the coldest end of a stove is a good place to winter them in.

FORCING-PIT.

Remove the plants from here to the conservatory as fast as the flowers expand, and introduce others from the reserve for succession, placing them first at the cool end of the pit, so as to excite them gradually. A few *Pinks* and *Sweet Williams* may be started, and plenty of *Lily of the Valley*, *Sweet Briar*, and other sweet-scented plants. *Gardenias* must also be started, and as *Stephanotis* is a great favourite, a plant or two should be placed at the warmest end of the pit. Maintain a fresh, growing, moist temperature of from 60° to 65°, or 70° with sun heat, and give air, warmed before it reaches the plants, at every favourable opportunity. Syringe early on sunny days, and keep a moist atmosphere, unless the weather is very dull.

PITS AND FRAMES.

These must be protected in severe weather, and abundance of air should be given to *Mignonette* and *Violets* when the weather is favourable. The early-potted *Tulips* and *Hycinths* under tan will begin to draw, therefore, remove them to a cold pit. A batch of *Mignonette* for succession may be sown towards the end of the month. Keep the plants in these structures as hardy as possible, by fully exposing them in mild weather, but do not give them any more water than is absolutely necessary. Remove all decayed and decaying leaves, and keep the atmosphere in as healthy a state as possible.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

SOWN succession of *Kidney Beans*; potted young *Cucumbers*; spawned and earthed fresh piece of *Mushroom-bed*; put some droppings, with a portion of long litter made short by cutting it, in a shed dry; took up more *Rhubarb* and *Sea-kale* to place in the *Mushroom-house*; and, as the heat was declining too much, put a lot of fermenting material in the house to prevent the necessity of putting a fire on. The first beds are producing plentifully, and the old beds in the open

shed are still producing usefully. There are unmistakable signs that in many families Mushrooms are becoming as much an every-day affair as Parsley, and it is a sad thing to be short of the latter. Whenever scarcity is threatened it is a good plan to fill some pots and boxes, and place in the houses, or fill a frame or part of a frame with it, with a little gentle heat under it. It is advisable to have one of these moles to fall back upon, as respects Sorrel, Fennel, Tarragon, Burnet, Chervil, and especially Mint, as, after Asparagus comes in, Mint is often wanted, and lamb, however great the delicacy, is nothing without it in the estimation of a connoisseur. Mint is a particular thing in some places, with us it lives only a short time, unless fresh plantations are frequently made.

It is well to notice, that in taking fermenting materials into a Mushroom-house, for first producing heat and then getting prepared for forming a bed, besides the annoyance of extra steam, to which reference was made lately, there is the possibility of taking in slugs and snails, and mice with the litter, which is not so likely to be the case if the material has been prepared, well heated, and thus dried in a shed. The heating makes these insects start, and therefore, though we thus lose a portion of the enriching power of the dung, we gain in more freedom from vermin. We have not yet noticed the nibbling of mice, but several bonnet-headed Mushrooms have been holed by snails. These may be trapped with greased cabbage leaves, and, better still, by a little brewer's grains laid in a heap; but the most effectual mode is to take a candle and lantern, and look over the beds and walls any time from ten o'clock at night to three o'clock in the morning. The snail seems to know instinctively the darkest and quietest hours. We have never seen them so large as in a Mushroom-house. We have taken some that looked like small adders, and almost as beautifully spotted. Such soon render useless a lot of Mushrooms if allowed to have their way.

As occasion offered, went on stirring the ground amongst young crops. Gave plenty of air to young Radishes, but they scarcely move in the dull foggy weather. We would have proceeded with slight hotbeds, but the hurricane took away most of our tree leaves, and until the shooting is over we must not go near the covers. A good stock of tree leaves is a great acquisition for a garden, as their mild heat enables us to bring many things forward; but for them we should have been at a standstill in all departments, as, without their aid, the dung from three or four horses would scarcely have sufficed for Mushrooms, let alone the wants of the kitchen and flower gardens.

We have as yet done little digging or trenching. In general we like the surface to be frosted first; but in such a mild season as this we would not have waited for this, if a press of other work and alterations had not caused the delay. All stiff clay soils, whether merely turned up one spit deep, or two or three spits in depth, would be the better of being ridged up in furrows, and the clearer these furrows show the mark of the spade the more will the frost act upon them in shattering them to pieces. In light soils it is better to leave the surface rough but flat, as, if ridged up, the soil would get too fine, and there would be a want of firm holding power for the plants. For gardening-purposes the soil cannot be too deep; and the shallowest soil will soon be deepened if, in trenching, the subsoil is broken either with spade or pick, left where it was at first, and at the next trenching a little of it is brought up and incorporated with the staple. It is wonderful how a thin hungry soil may thus be deepened and improved, especially if there is a good rubbish-heap of decaying vegetable matter to go to. Such rubbish-heaps of all refuse vegetable matter will be greatly improved if short grass from lawns and a little litter be placed below them in summer and mixed with them, and a little earth be thrown over all. The grass, &c., will cause the whole to ferment kindly, and the earth will keep in all the fertilising gases. Wherever dung is scarce much must depend on the goodness of the rubbish heap, and everything that will rot and decay should be carefully husbanded there, except seed weeds, or what will be best disposed of in the charring and burning heap. Many of the remains of vegetables would come in useful at the farm for pigs, &c., to nibble at, and at least amuse themselves; and when dung can be had in return, a fair exchange is all right; but when it is supposed that it is waste to let manure from the farm find its way into the garden, then every bit of vegetable should be kept in the rot-heap to help to produce other vegetables. When spent quarters are to be cleared, it is not a bad plan to dig them, or rather trench them down, and then they rot and give off their manuring properties slowly; but in this case they often prove a feeding place for gardeners' enemies in

the ground, and in general it will be found preferable to rot them in the rubbish heap, kept covered with earth whenever there is an escape of gases, in other words, whenever there is the heat from active decomposition, and the heap will be all the more valuable from this heating and earth-covering. A part of the heap already decayed may be used for throwing on the surface; a little salt and lime will also be useful if added to the heap; and so for all soils not abounding in calcareous matter would be all kinds of lime rubbish. On chalky soils the application of calcareous matter in any shape is generally of little avail; but there are many places where strong loam is resting on clay, and a great depth of chalk below the clay, and in such cases the bringing up the chalk and surface-dressing with it is often of great advantage. If spread on the ground before frost it will generally be shattered and broken enough.

FRUIT GARDEN.

Merely a repetition of previous weeks; have shut up the Peach-house, and put a little fire on just to move the plants gently. For temperature in various houses, see memoranda of a fortnight ago.

ORNAMENTAL DEPARTMENT.

The chief trouble has been to keep damp from late-struck Geraniums, and other bedding plants in cold frames and pits. For several reasons, the chief anxiety not to disfigure fine beds and borders, our cuttings were unusually late this season, and the damping of the foliage has been rather troublesome in cold pits and frames. It is better every way to place them in a house where a little fire heat can be used. No greater mistake can exist than the supposition that gardeners can have their own way in this respect, even in "very tidy places." Such a mode has suited us hitherto, and "We want no change" is often the reply to plans that have cost consideration and trouble. That is no reason why every one should not try to obtain what would be the most suitable, as exemplified in the letter and plan of a Cucumber-house, given by Mr. O'Donnell at page 524. Such a house is far before a lean-to pit. If mostly above the ground level, and fully half of the sides of glass, it would be better still. One advantage of the plan given is that the beds are the width of the paths from the sides, and therefore receive more light from the roof in winter. The lobby and double door are a great advantage, especially in winter. But, notwithstanding all these advantages being made apparent, many, very many, must do what they can with flat lean-to pits, or, perhaps, still flatter frames. Unless greatly elevated at the back, no common frame or pit with the same inclination receives any direct light, or rays from the sun, for nearly half the width in front. More light, and the chance of giving a little help from fire heat, are of great advantage for most ornamental plants that are grown in pots.

In such places, and in all houses kept cool, no watering should be given unless absolutely required. The moisture in the air has generally been sufficient where no great amount of artificial heat was given. *Bulbs* that have now filled their pots with roots may be gradually forced, but the heat should be raised by degrees—say Hyacinths beginning at 45°, and rising in ten days to 55° and 60°; Tulips not quite so much; and Crocuses should seldom be above 50° with artificial heat if it is desired to have the colours bright. Narcissus will stand as much heat as Hyacinths, but when coming into bloom the temperature should be gradually lowered before they are taken to the greenhouse or window. Hyacinths when showing their bloom-stalks will often be better of a pot or a paper funnel placed over them, to draw up the stems, to give the florets room; but in all cases as the bloom opens the plants should have all the light possible. Placing them in the middle of the room, on the top of the mantel-shelf, or on sideboards, is an act of cruelty which, if the poor bulbs could speak, they would soon tell us all about. Hardy shrubs brought forward in heat should have the temperature gradually reduced before they are taken into a much colder place; and all shrubs that are to be forced should also be brought on by degrees, as subjecting them to a high temperature at once is apt to start the flower-buds prematurely and cause them to drop, whilst it gives an extra stimulus to wood-buds to start into shoots.

The weather has been everything that is desirable for greenhouse plants; even the most sensitive of the hardwooded ones could take all the mild air that could be given them if there was enough of fire heat in foggy days to keep the air in motion. Extra heat otherwise is to be avoided, as the mild temperature has encouraged growth, whilst there has been little sun to consolidate the growth.

Now is a good time to cut in many stove climbers, as Allamandas, Stephanotis, Passifloras, &c., and to shake out and report those previously pruned, and now showing their fresh shoots. Cuttings may now be made of Euphorbias, Poinsettias, &c., to be grown on for next autumn and winter. Most stove plants that have been at rest in winter, as Clerodendrons, may also be pruned back to a few buds of last year's shoots, and as soon as the buds burst the plants should be shifted into smaller pots, be benefited with a little bottom-heat, and receive another shift as soon as the pots are full of roots. Care should be taken that Ixoras are now free of scale and green fly, and they will be much benefited if the pots are plunged in a mild sweet heat of from 75° to 80°, the top heat averaging from 60° to 65°. As time permitted went on with potting Mosses, Ferns, &c., getting a lot in small pots, so as to form parts of vases of flowers in-doors, &c.

Most of our work for the week has been moving Rhododendrons and other evergreens, and fresh turving some borders, which it is considered we should be better without. Where much heavy work with evergreens is required to be done, it would be economy to have a stout low-wheeled little truck for the purpose. In laying turf, and moving turf to be relayed, much time and labour are wasted if the turf is not taken up in pieces pretty uniform in width and thickness. Inattention to these little matters makes a great difference in the amount of work that can be done in a day, and even careful men, and good at taking up turf, need to be reminded of it. At this season of the year many men will attempt to lay turf by standing and stooping—a rare stoop for a tall young man; but where a regular job has to be gone about, turving cannot be satisfactorily done by a man working in such a stooping position. The importance of a dry day, and the ground moderately dry, will be seen from the circumstance that the workman ought to be on the unturfed ground, and on his knees when at work. A kneepad should protect his knees, and a moveable pad be used for his legs. Every piece of turf should be put down properly in its place—a matter easily done if the turves are uniform in thickness, but which requires a good deal of packing if the turves are not equal in thickness. If the turves are not left level and well packed, no beating or rolling afterwards will ever make a smooth level lawn. Of course all old ground that used to be dug must be thoroughly beaten before turving, and even then most likely it will fall in the course of years. Where much turving is done, and the ground requires much levelling and regulating previously, the simplest plan is to use a number of lines of cord, stretched at the proper sweep and level, and then the workmen have only to turf up to the lines. In making banks of a regular uniform slope, a good plan is to have one line stretched firmly for the edge of the top, and another for the edge at the bottom, and a heavy rod of the requisite length moving between the two lines will secure a uniform slope all throughout.

As to evergreens, we may mention that Rhododendrons will not flourish in a soil abounding in calcareous matter. In almost every other soil they will grow if enriched with rotten leaf mould. In our soil our only chance is to turn down the loam and turn up the clay, and plant in clay, and a little leaf mould and sand. They will not look at our stiff loam, which has a good portion of calcareous matter in it. After all they generally do best in such soils as the native Heaths delight in; but they do well in heavyish loam, in rich sandy loam, and, in fact, in any loam we have met with free of calcareous matter.

A falling barometer is giving us warning that ere long we shall be able to bring up our leeway in house-work of all kinds. Hitherto the weather has been too favourable for outdoor work to do more in-doors than what was absolutely essential.—R. F.

TRADE CATALOGUE RECEIVED.

William Pontey, Huddersfield.—List of Forest and Ornamental Trees, Shrubs, &c.

COVENT GARDEN MARKET.—DECEMBER 30.

SUPPLIES are well kept up and prices maintained, Pines and Grapes both being slightly in advance of last week. Pears are becoming comparatively scarce, and are confined to Winter Nelis, Ne Plus Meuris, Colmars, and Glou Morceau. Large quantities of Potatoes are on hand.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOK (*T. T. Isleworth*).—You can have "In-door Gardening" and "Out-door Gardening" for Is. 6d. each at our office. The early Pea you refer to was Dickson's Early Favorite.

MULCHING ROSES (*M. H.*).—Half-rotten dung will be better for mulching Roses than that in a state of fermentation.

NESPOLI DI JAPONI CULTURE (*An Irish Subscriber*).—We believe it to be the Loquat, *Mespilus* (*Eriobotrya*) japonica, and it is not so fine either in Italy or Malta as it is in India, because the climate is not so suitable. However, we sent your inquiry to "J. H.," and this is his reply:—"It is not the Loquat, but what is commonly called the Maltese Medlar. I raised my plants from seed out of some fruit bought of a fruiterer in Oxford Street. I have tried grafting without success, but I have fruited a plant in three years by growing it in the stove in summer, keeping it in a greenhouse in winter, and taking it out of the pot and cutting the tap root every year. It is very liable to the attacks of insects of almost every sort, although it would not so appear from the leaf. The flower is large and fragrant, and the fruit is of a yellow colour, with four very large seeds inside, and of rather an insipid flavour. I cannot succeed in grafting it on any stock, and it is not worth the trouble except for the blossom. It should have plenty of heat, air, and moisture in summer, and complete rest in winter; frost injures it, however, much. It will fruit in 12-inch pots. It is called, I believe, 'Nespoli di japoni' by the Italians, but it is not at all equal to the true Loquat. It should not be watered with manure water at all, or it will not bear; by cutting the tap roots it will bear in three years."

PELARGONIUMS AND FUCHSIAS NOT BLOOMING (*A Subscriber*).—From what you state we think that all that your plants require to make them bloom more profusely, is a more plentiful supply of air, poorer soil, less pot room, and to be kept cool, close to the glass, and without shade.

MANURE FOR FLOWER-BEDS (*Idem*).—It would do them good, but put it a foot below the surface, and the roots will find it. In consequence of this deep rooting the plants will be enabled to withstand drought. If mixed with the soil manure is apt to make the plants run to leaf, and we, therefore, recommend putting it a foot below the surface, or covering the beds early in July with 2 or 3 inches of very short manure. The effect in both cases is much alike, although the mode of action is different, for in the first case the roots are induced to go deep down, and are, therefore, not so liable to suffer from drought, whilst in the other evaporation is to a great extent prevented, and, at the same time, the soil is enriched by the rains washing into it the fertilising agents of the manure. A dressing of leaf mould dug in now would make the soil sufficiently rich for planting in.

HRAVIEST BUNCH OF GRAPES (A Subscriber).—The weight in a given space depends upon the closeness of the berries to each other. The statement is Speechley's own.

DESTROYING WORMS ON LAWN (A Constant Reader).—Put a stone of lime in a hogshead, and pour in forty gallons of water. Stir well up, and allow the liquid to stand forty-eight hours. Roll the lawn well, and during showery weather, the evening before it is watered with the clear lime water, and apply this from a rose watering-pot. The worms will either be killed or brought to the surface, and the lawn should be swept with a broom, and the worms carried away. Success, especially at this season, depends on giving the ground a thorough soaking of lime water. It may be necessary to repeat the watering at intervals of a fortnight or three weeks.

FORMING A FERNERY OF TREE STUMPS (E. P.).—Your north-west aspect will be sufficiently shaded for the majority of hardy Ferns to do well. The shade of the large trees will prevent any danger of their being scorched. We should begin by throwing up a bank of loose rubbish against the wall, and if more stones than soil all the better. This mound, or bank, we would have equal in height to the wall, all but 3 feet, and as wide at bottom as it is high, forming it, however, in an irregular serpentine fashion. At the base of the bank lay a row of tree stumps, and fill up the interstices with soil, which may consist of peat and loam in equal parts, or failing the peat, the top soil from a wood from which the leaves are never removed but allowed to rot. Lay another tier of stumps and then fill up with soil, and so on. Work the soil into the vacant spaces as you proceed, instead of first making the rottery and then filling in the interstices, leaving the parts beneath the stumps hollow. Build up firmly, with a straight face in some parts as if it were a wall, in others sloping, and in some parts much wider than in others, and as tree stumps are more easily placed than rock stones, we should certainly have the doorway formed of the stumps placed one upon the other, and the other end, or exit, open. On the other side for next the rottery against the wall should be a path 4 feet wide, the stumps should be placed so as to correspond with the side next the wall, and this part may be of any width, height, or form desired. The main points to be attended to are to build up the rottery firmly, to fill the openings with soil, and to make its appearance as bold and rugged as possible. The stumps for the most part should be about half buried in the soil, some almost entirely hidden, others entirely bare, and all firmly placed. In addition to filling up the hollows as the stumps are laid, the whole should be gone over afterwards, and any openings where Ferns are to be planted should have soil placed in them. All the commoner kinds of British and hardy exotic Ferns would do fairly. Of these we can only name a few—viz.:—*Lastrea Filix-mas* and varieties, *Osmunda regalis*, *Lastrea oreopteris*, *L. recurva*, *L. dilatata*, and *L. spinosa*; *Polypodium vulgare* and varieties, *P. dryopteris*, and *P. phegopteris*; *Poly-stichum lobatum* and varieties, and *P. angulare*; *Scopodendrium vulgare* and varieties; *Asplenium adnatum nigrum*, *A. trichomanes* and varieties, *A. viride*; *Allosorus crispus*; *Dicellaena* spicant and varieties; *Cystopteris fragilis*, *dentata*, and *Dickiana*; and *Athyrium Filix-femina* in great variety. Of exotic Ferns may be mentioned *Lastrea intermedia* and *L. marginalis*; *Polystichum proliferum*, *P. pungens*, and *P. acrostichoides*; *Struthiopteris germanica* and *S. pennsylvanica*; *Oncola sen-bilis*; *Osmunda interrupta* (Claytoniana), *O. spectabilis*, *O. cinnamomea*, and *O. gracilis*; and *Cystopteris bulbifera*. All require a plentiful supply of water in summer.

WATERING OVERHEAD AZALEAS AND HEATHS (Elizabeth).—Watering the plants overhead through the rose of a large watering-pot would not do any great harm to Azaleas placed out of doors in summer, if the water was not given to excess, and only on the evenings of hot days. The night dew and rain are quite sufficient for Azaleas after the buds have set, and for Heaths watering overhead is more or less injurious. We conclude that the plants were watered overhead only, and had no water or an insufficient amount of it at the root, which, with the pots exposed to the sun, would account for the plants dying. Or it may be that the soil in the pots has been so soddened as to cause the fibres to perish, as those of Azaleas, Heaths, and all hard-wooded plants will do if the plants are potted so that the water drains to not from the collar, and if it regularly given without regard to their requirements. The soil in which they are grown should never be allowed to become so dry as to affect the foliage, and, on the other hand, it should not be so regularly watered as to be very wet. The right condition is between the two extremes. There is no work published on the culture of Azaleas. Any information which you specially wish we shall be glad to furnish.

PROPAGATING HARDY FERNS FROM SPORES (B. W. W.).—Choose a pot which a bell-glass will just fit within the rim, place a large crock over the hole, half fill the pot with smaller pieces, and on them place half an inch of moss; then fill the pot to the rim with the following mixture—viz.:—sandstone broken in all sizes from that of a grain to a hazel nut, sandy fibrous peat, and yellow fibrous loam, of each equal parts, adding to the whole one-sixth of silver sand. Put over the surface a very small quantity of sifted soil, and make it firm by pressing it with the hand. Put on the bell-glass, and if it fit closely on the soil it is all right. Remove it, and stand the pot in a pan in a rather shady but not dark part of the greenhouse, for what is wanted is a diffused, though not a strong light. Give a good watering all over the surface through a fine-rosed watering-pot, filling the pan with water. Now, take the frond with the spore-cases open, and holding it over the pot, rub it with the hand on the under side and a kind of brown or yellow dust will fall on the soil. You may scrape the spore-cases from the back of the fronds, but if the dust fall so as to make the soil brown or yellow, it is enough. Press the surface gently with the hand and put on the bell-glass, taking care that it touch the soil all round. Keep the pan, or saucer, full of water, and give none on the surface except it become dry, which it never ought to do, nor will it if sufficiently shaded and the saucer be kept full of water. When the surface becomes green tilt the bell-glass a little on one side at night, and as the soil becomes greener tilt it higher, giving a gentle watering now and then to keep the surface from becoming dry. When the plants have made two or three fronds gradually remove the bell-glass, and pot off the Ferns when they can be handled safely. The pots may be placed outside exposed to frost, but then the vegetation of the spores will not be so speedy and certain as when the pots are placed in the greenhouse.

ROSES GERANIUMS (E. J.). Roses with much over the roots should not have any liquid manure until they commence growth in the spring. We do not think that Scarlet Geraniums cut down and covered with ashes would survive the winter. If they did they would be weak and flower late.

PERFECTANTIA SPINOSA CULTURE (S. Horner).—The greatest drawback to blooming this plant is keeping it in too close and warm an atmosphere. It requires a cool airy situation in a light house, a fair amount of pot room, and perfect drainage. Your plant, we should think, requires potting, which may be done from the present time up to March, and for so large a plant, a 15 or 18-inch pot would not be too large. A compost of good hazel or yellow loam suits this plant, that from rotted turves being the best, and it then needs no manure; add, however, one-third of well-reduced leaf mould, and a free admixture of sharp sand. Drain the pot thoroughly, and pot with the neck or collar rather high in the centre of the pot. Keep the plant well watered whilst growing, and at other times moist. It requires about as much water as a *Camellia*. Ace is all that is wanted to make it flower more profusely.

SEEDLING GERANIUMS, AMARYLLISES, AND ACHIMENES (A Subscriber, J. H.). Gloxinias and Achimenes flower the same year the seed is sown. If sown early, say in February or March, on a heated and grown on in the bed, with liberal treatment they will flower in autumn, but better in the second year. It usually requires three years to bloom seedling Amaryllises, and then the treatment must be such as will encourage growth.

TRANSPLANTING A COLEK TREE (G. S. A.).—It is usual for this and every other kind of forest tree to form a tap root, but as yours would be a transplanted tree when planted, there is no danger to be feared on that account. It is only when seedling trees are allowed to grow up where sown that there is danger to be experienced from the tap root. We have moved trees much larger than yours, by taking out a trench a yard from the stem and 2 feet deep, cutting off all the roots we came across, and working under the ball at that depth, cutting all roots towards the centre of the ball. This we did in September, and in the following September we moved the tree, meanwhile filling up the trench. In this way we have within a year transplanted trees with a good ball and an abundance of fibres, although we had otherwise no prospect of doing so. We should try to remove the tree in March with a ball, and if we found that there was no possibility of doing so, we would fill up the trench again and wait another year. It is of no use attempting to move trees of this kind unless they have a good ball with plenty of fibres in it, and, at the same time, there is no necessity to leave a quantity of loose soil above the roots.

TEMPERATURE FOR FERNS AND FANCY PELARGONIUMS (Henry Higgins).—Maiden-hair, Gold, Silver, and other Ferns is not definite enough for us to tell you the temperature required; but you say they are greenhouse Ferns. Now, there is no Gold Fern that we are acquainted with except *Gymnogramma ochracea*, and only one Silver—viz., *Gymnogramma tartarea*, that will do in a greenhouse, and then the house must seldom be allowed to have a temperature of less than 45°. The others require a temperature of 55° from fire heat in winter, but the thermometer may occasionally read as low as 50° without injury to the plants. The Maiden-hair will winter safely in a temperature of from 40° to 45° from fire heat, which is also suitable for all the greenhouse kinds. By day the thermometer should read 5° higher on dull days, 10° when they are cloudy with clear intervals, and 15° with air, on bright days. Fancy Pelargoniums require a temperature of from 40° to 45° from fire heat, with an increase by day as before mentioned, affording them abundance of air, light, and a rather dry atmosphere.

STAGE FOR GREENHOUSE (A Country Clergyman). We should have a shelf about the front 18 inches wide, and also at the end from the doorway; it may either be of stone or of laths. This will, of course, be over the pipes or flue, and should be on a level with the bottom of the front wall-plate. Allow 3 feet for a pathway from the front shelf, and have a stage of wood at the back, the first shelf 9 inches from floor, and the others receding towards the back, and 9 inches above each other; the last shelf should be 4 feet from the glass. Your stage will thus have seven shelves, the first 7 inches broad, and the others an inch wider progressively upwards until the fifth is reached, when those above it need be no wider. The shelves should be inch red deal, or they may be formed of laths 1½ inch by 1 inch. It would improve the appearance if the end of the stage facing the doorway were made to rise from the pathway in the same way as along the back.

BOOKS (H.).—The little book you have from our office, if you multiply the quantities by ten, will guide you sufficiently to aid your own good sense. There is no work of the kind you mention.

COIL-PLANTING VINES.—Mr. Rivers informs us, that the surface of the soil over the coil (see page 325), should be covered with "2 inches," not "10 inches" of rotten manure, as there stated, in order to encourage the buried part of the stem to emit roots rapidly.

ESPERIENE VINE.—*Tycho asks*—"Is it possible to obtain cuttings, or eyes, of the genuine Esperiene Vine mentioned by 'UPWARDS AND ONWARDS'?"

HEATING BY GAS.—*Tycho also asks*—"Can any one give me any information of an apparatus for heating greenhouses or rooms by gas, made by R. & W. Watson, or R. & W. Wilson, London?"

COLOURING FOR OLD FRUIT-TREE WALL (E. J.).—A bushel of lime flowered down, passed through a fine sieve, and with about two or more ounces of lampblack, or blue-black (the latter is the better), made into a paste and mixed with a sufficiency of water, passing all through a sieve, will make a nice colour, the white of the lime being toned down. If the walls are old and unsightly, it would be advisable to add a peck of fine grey sand and as much Roman cement. If much moss, &c., be on the wall, it would be as well to give a coat of the lime first. The drier and cleaner the wall when the wash is applied the better, and the longer will the colouring stand.

EDGING FOR BORDER (Surgeon, Half-pay).—We have found Thrift form a good edging where Box would not grow at all. Another very good edging plant is the small-leaved Ivy, common enough in hedgerows and woods. If you particularly wish for a plant-edging, we should advise you to try Thrift or Sea Pink, which makes a very close and tractable edging, and is, besides, very pretty when in bloom, green and grass-like at all seasons. Glass edging-tiles would be the most permanent and require no after-care, but they are rather expensive at first.

LYCHNIS SENSO.—W. S. wishes to know where this can be obtained.

COMMUNICATION (A Gardener Lad).—Write on one side only. Any sized paper, the thinner the less postage you have to pay. Do not fasten the leaves together, but number each page.

FAILURES (A. E. C.).—There are many things for which even the best gardeners are totally unable to render a reason, and we feel just in the same predicament as your gardener, and can give no reason from any description you give us. There has been no frost to injure such plants if the temperature had become reduced. The *Encelia* would have done better nearer 50° than 65°, but in from 60° to 65° the *Begonias* and *Cactus* ought to have done well. We have known some such effects from the soil being not soaked repeatedly with cold water in such dull weather, but that was not likely to be the case. Have you been painting the houses lately? Have you been lime-washing the walls with very hot lime, fresh? or have you had the pipes fresh painted, without allowing them to become well dried before much heat was applied? Even when lampblack and oil are used, a high temperature will throw off fumes that will injure most flowers, unless there is a great deal of air on. A rusty pipe is used at once. The matter is of so much importance that we shall be glad if some of our readers will give it their attention. There is no suspicion of poisoning the water? Or has anything deleterious found its way into the water? We have known an instance of a small stove from which the plants were removed in the morning, and all the walls and stages washed with fresh magnesian limestone and sulphur, and in a week the most of the leaves and flowers dropped.

VINES FROM EYES (Eques).—Vines may be raised from eyes in a coolinery or greenhouse. If you obtain the shoots now you may keep them with the lower ends stuck in moist but not wet soil, until the middle of February, then make the eyes, pot them, and place in the greenhouse, and keep the soil just moist until the shoots appear, when they are to be well supplied with water. You will see what was said on this subject at page 529 of our last Number.

TREES AND SHRUBS FROM SEEDS (Idem).—You can grow all the following from seed:—*Thuja occidentalis* and *orientalis*; *Cupressus macrocarpa*, *Lawsoniana*, *Goveniana*; *Larch*; *Lalurnum*; *Juniper*; *Red Cedar*; *Holly*; *Cedrus deodara*; *Pinus sylvestris*, *pinaster*, *halensis*; *Phillyrea angustifolia*; *Evergreen Oak*; *Enomyrus europæus*; *Strawberry Tree*; *Spanish Broom*; *Berberis Darwinii* and others; *Mountain Ash*; *Lilac*; *Laurel*, common and *Portugal*; *Laurustinus*; *Privet*; *Sweet Briar*; *Judas Tree*; *Chaste Tree*; *Bead Tree*; *Mahonia aquifolium*; *Lycocateria formosa*; *Cytisus spinosus* and *triflorus*; *Cryptomeria japonica*; *Araucaria imbricata*; *Calycanthus*; *Rhododendron*; *Azalea*; *Ailanthus glandulosa*; and *Rhamnus alaternus*. These are some that strike us at the moment, and there are many more which we do not now think of, and even if we did it would be of no use, for seeds of such plants are not always to be had, nor is it certain that they will grow when you have obtained them. Seeds of any tree or shrub which you can obtain fresh you may grow, and when you have procured them we shall be glad to assist you, if informed what they are.

LAYING DOWN A LAWN (A Constant Reader).—If you can obtain turf from a piece of ground where the grass is naturally short, close, and even in surface, and above all free from Daisies, Plantains, Dandelions, and other perennial weeds, then we should prefer employing turf to sowing a mixture of lawn grass seeds, for you would obtain a lawn at once; but if seeds are only to be had where you can get them, and not where you would like to have them from, then we would advise you to sow a mixture of lawn-grass seeds on your levelled piece of ground, taking care to have it free from perennial weeds, and in good tilth. Sow the seeds during the first showery weather in April. The seeds are best sown just before rain; after sowing, the ground should be gently raked over with a wooden rake and immediately well rolled, and for this the surface must be so dry as not to cling to the roller. By no means sow when the ground is wet, but, on the contrary, when it is in good working order. By July the grass will grow sufficiently to be fit to mow, afterwards cut it throughout the summer and autumn every three weeks, except in dry weather. The more it is rolled the more the grasses will tiller, and the firmer the lawn will be. If you were to give it a dressing of well-rotted manure in the following February or March, and brushed this in during showery weather in April it would vastly assist in forming a bottom, help to keep off moss, and insure a rapid growth, without which you cannot quickly obtain a close lawn. If you object to the manure, a dressing of soot will be less objectionable. During the second summer the lawn may be mown every ten days, and you will have a lawn of very fine grasses without the weeds usually found on those laid with sods, and it will not be liable to become mossy so soon as if turf were laid, but you must also bear in mind that it will not be so soft to walk upon. In a year you can have a good lawn by sowing a mixture of lawn grass seeds, and you can have one at once by laying turf. If you do not mind the appearance, and have an eye to ultimate effect, then we advise you to sow the ground, and if you can obtain good turf and do not mind the expense, then lay sods at once. Procuring and laying turf is much more expensive than sowing. Whatever you do, do not lay bad turf, nor sow a mixture of grass seeds unless suitable for the soil and situation.

GRAPE SHANKING (J. Mackenzie).—We should say the fault is partly owing to the roots of the Vines going so deep, and partly owing to over-cropping. With the Black Frontigan ripening so kindly without signs of shanking, we do not think that the fault is owing to the kind of Grape. The Golden Hamburg is tender in many places, and will not stand the same amount of direct sun as most other Grapes. The leaves are apt to be scorched, and that affects the fruit. If the Vine is farther from the glass, say from 18 to 24 inches, it will most likely answer better, and more especially when it has all the stock to itself instead of a part. The part of the pit might be examined as to the roots where the shanking is most prevalent; but we would be inclined to try what a thinner crop and watering whilst swelling would do. It would be well every way if the roots went no deeper than the 3 feet.

INSECTS (N.).—The white powdery covering on the Beech bark is the secretion, in vast quantities, of a waxy nature, from the bodies of countless individuals of a very small species of *Coccus*, whose history has not been thoroughly investigated. Scoring the bark may be of service, but scouring it would be much better.—W.

WEATHER WISDOM.—A correspondent, John Bryan, says, "Will 'X' state how a chart should be drawn out for keeping the necessary notes recommended by him at page 525? Then, as to the instruments required; this is the greatest difficulty, for they are very expensive. There are some barometers cheap enough, but I should like to know if they are to be depended on. Will 'X' tell me which is the best kind, and what would be the lowest price for one that could be depended upon?"

HEATING FROM BOILER BY THE BACK OF KITCHEN FIRE (W. M.).—We are not quite sure that we understand the description of the boiler, but if it is 12 or 14 inches long, and 9 inches deep, and we presume much the same in width, and set behind a kitchen fire, with fire applied chiefly to one side, then we do not think it would be sufficient to keep the frost out of an open glazed orchard-house 74 feet long by 12 feet wide, 11 feet high at back, and 5 feet in front, if the pipes from the boiler must pass through the wall and be placed in the house 2½ feet from the floor. If the boiler could be heated below as well as on the side, and the fire could be confined against it at night, it ought to heat about 150 feet of four-inch pipe, and that would keep out all ordinary frost; but considering the height at which pipes must be placed, and also the size of the house, we think it would be more economical to have a stovehole and boiler for the purpose, so that you could have the pipes just above the floor-level and also near the front of the house. More piping will be required if they are placed near the back wall. We would advise trying the half of the house first, if you resolve on the kitchen boiler. It is much against the success of the plan that the boiler is so far above the greenhouse floor.

REMOVING A LARGE HOLLY (C. P.).—Were we sure of this mild weather continuing, we would move the twenty-foot-high Holly tree from the hedge-row directly, beginning with a trench 6 or 7 feet from the stem, working the soil from among the roots with a mattock and spade, carefully saving the roots, undermining and securing as large a ball as we could. The place should be well trenched where you propose planting, and the roots should be nicely laid out, packed securely, the ground mulched to keep out frost, and if severe frost should take place in spring, a little old hay or litter may be thrown lightly over the top, which will check evaporation and lessen the intensity of the frost, which would burn up and scald the trees from the want of root-action at first. In sunny days in April, and onwards in summer, a little water should be thrown over the plant in the middle of the day. If there should be signs of severe frost before you read this, you had better defer planting until the end of March. The safest plan of all, if you could defer the operation, would be to dig down a trench about 20 or 24 inches from the stem all round, cutting all the roots, and going deep enough to cut the most of the tap roots, make some holes in the ball, water these two or three times in spring and summer, fill up round the ball with fresh sandy soil and leaf mould, and in the end of September lift and plant. The outside of the ball will have new fibres formed.

GROWING FRUIT UNDER GLASS (J. R.).—We can give you no great encouragement as to growing Vines, Oranges, and other plants in the way you propose in your contemplated corridor, which is to be 40 feet long, 11 feet wide, and 8 feet high of opaque materials on each side, a flatish span-roof of glass, ends facing south and north. As Portland cement is what you are conversant with in your trade, we will at once allow that you are more qualified to judge of the sides of houses formed of wood standards 3 inches by 2 inches, 18 inches apart, and 8 feet above ground, with laths nailed outside, and plastered and rough cast with Portland cement and rough gravel, would be drier and warmer than brick, if brick was made with small joints. Besides, the bricks might be made waterproof outside with tar, and when thoroughly dried would give off no unpleasant or deleterious smell. We believe that the concrete walls might be made very pretty as you suggest, by making devices and figures with shells on the concrete; but we have no faith in your trees doing well trained against the standards inside, and with no light except what may come from the span-roof, 8 feet from the bottom of the trees. Vines, &c., would flourish chiefly after they grew up underneath the roof, but then if they grew thickly there, there would be no light for the plants below them. All plants on the floor would be drawn to the glass on the roof. What we would suggest for a 12 or a 14-foot-wide house, or even for one 11 feet wide, if you cannot have it wider, would be to have stronger posts, say 4 inches by 5, 5 feet apart, and 3 feet above ground, the intervening spaces being supported with such pieces as you propose, in order to carry out your plan of cementing; but in doing so we would leave openings in the side for ventilators—say six of them, 20 inches long and 15 deep; and from a stout rail morticed in at 3 feet from the ground, we would have the glass roof, meeting in the centre at the apex, 10 feet from the floor. What you planted at the sides, 15 inches from the wall, and trained some 15 inches from the glass would then do well, and you might ornament the inside with composite tables as you propose, and keep plants of any kind in pots. For such a house you would need one ventilator at the apex in the middle of the house, and a large space below the apex at each end should be made to open, and even the doors could stand open in very hot weather. The best mode of heating, if tender plants are to be kept, would be by hot water. If we know what you decide on, we shall be glad to advise you. Could you not put up a house against your living-house and decorate the back wall? Light is indispensable for plants.

CONSTRUCTING A CUCUMBER-PIT (Montgomery).—For a pit 9 feet wide, and 3 feet in height at front, 4 feet at back will be too low—that is, the glass will be too flat. Better raise it another foot, or else make the front 2½ feet. Suppose your sunk paths to be 2½ feet wide, the bed will be from 6 to 6½ feet wide, and for that bed you would require either two or three four-inch pipes for bottom heat, and if you wanted a higher temperature in winter, three four-inch pipes for top heat. You cannot do with less than two pipes for top heat. We have lately repeatedly stated the simplest mode for arranging the bottom pipes, covering them merely with clinkers before placing the soil, or the material for plunging cuttings.

NAMES OF PLANTS (Agnes).—1, *Cantua bicolor*; 2, *Eupatorium leucoides*; 3, *Sempervivum*? crushed and discoloured. (*Ignorant Inquirer*).—1, *Linum trigynum*; 2, *Maranta bicolor*; 3, *Coleus Verschaffeltii*; 4, *Dra- cæna ferrea*; 5, *Pilea muscosa*. (*A Constant Reader*).—1, *Gymnogramma cæna ferrea*; 2, a mere bit of some *Pteris*; 3, *Cyrtomium falcatum*; 4, one of *trichæra*; 5, *Polystichum angulare*. (*A Subscriber, Ballinacree*).—1, *Asplenium vars.* of *Polystichum angulare*. 2, *Adiantum nigrum*; 3 and 6, *A. trichomanes*; 4, *Adiantum capillus-Veneris*; 5, *Ceterach officinarum*; 7, a *Saxifraga*. (*W. W.*).—1, *Lastrea*, appears to be a narrow form of *L. dilatata*, but the specimen is imperfect; 2, *Lastrea Filix-mas*. (*Alpha, Acton*).—1, *Acrophorus hispidus*; 2, no fruit, probably *Lastrea decomposita*. (*G. E.*)—1, *Trichostomum fasciculatum*; 2, *Bryum ligulatum*; 3, *Hypnum rutabulum*; 4, *Hypnum alpestrum*; 5, *Equisetum limosum*; 6, *Trichostomum aculeatum*; 7, *Dicranum bryoides*; 8, *Tortula muralis* (?); 9, *Grimmia arctica*; 10, *Polytrichum undulatum*; 11, *Pontania antipyretica*; 12, *Bryum turbinatum*, or nutans; 13, *Bartramia arcuata*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the ten days ending December 30th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE BIRMINGHAM AWARDS.

WHEN persons attempt to stifle inquiry and repress investigation, it generally arises from a secret conviction that there are matters which will not bear the light, and from which it is the interest of parties connected with them to divert public attention. I was very forcibly impressed with this fact in reading the communication of "BRAHMA;" and your readers who have perused his letter with care must have been struck with the circumstance that, whilst he displays his familiarity with subjects and events quite foreign to the question, he has not adduced a single fact in support of the positions for which he contends. His letter is purely deprecatory. According to his representation, the gentlemen who exercised the office of judging at the late Show at Birmingham are such perfect paragons of wisdom and impartiality, that dissent from their decisions is sheer impertinence, and can only be accounted for on the supposition of its arising from disappointed parties, who, not being able to bear the defeat of their expectations, "make up by clamour what they lack in argument." After thus at one sweep disposing of the complaints of the dissentients, it might have been expected that "BRAHMA" would have avoided the same defect; instead of which, he has furnished a practical illustration that, to say the least, the clamour minus the argument is not all on one side. "BRAHMA," it is true, is lavish in his denunciations against those who do not bow with implicit submission to the awards of his clients, stigmatising them as men who "doubtless believe they have been hardly dealt by," but are not "so happily constituted, or so capable of cool judgment in their own matters, as to justify them in impugning the awards of experienced and honourable men" (of course, none of the dissentients have any claim to either honour or experience), or not "able to overcome evil passions and prejudices, and to act dispassionately, when smarting under disappointment," although he is charitable enough to hope that "when they cool down," they will become sensible of the enormity of their conduct, and be touched with a feeling of compunction for their misdeeds. But with all this vehemence in arraigning the conduct and motives of the other side (a vehemence somewhat, by the way, remarkable, if the disclaimer put in by "BRAHMA" to being an "exhibitor" means that he has no personal interest of any kind in the matter), where are his arguments? He is very facetious, again, on Solomon Eagle and Eastern Pashas, which may be all very witty, but unfortunately has no connection with the subject.

To bring the matter, however, more closely to an issue, should "BRAHMA" return again to the charge I beg his attention to the following questions: 1st, I wish him to explain the points of superiority in Admiral Hornby's Dorkings over those of Viscountess Holmesdale? 2nd, In what the qualifications of the Brown Red cock and the old Piles consisted, whereby they were entitled to the prizes respectively awarded to them? and 3rd, Why the Black Bantams which have been disqualified at a show held since, should at Birmingham have obtained the first prize? But as, according to "BRAHMA," he "attends few shows," he may not be aware of these facts. Were he, however, to visit more of these exhibitions, he would probably become acquainted with some facts of which he appears to be ignorant, or which at all events he ignores. He, for instance, would have learned that in the show held since that at Birmingham, the decisions at the latter not only in reference to

Black Bantams, but in Dorkings, Cochins, Game, and, indeed, in almost every other class, have been reversed. And had he been an exhibitor where fowls notoriously the worst carried off the palm from birds having greater claims, he might possibly have been as loud in his complaints as those whom he now censures.

Towards the close of his communication, however, he discloses what it is that has caused his ire. It is the Poultry Club, "the point of whose offending" is, that they have denounced the practices of the Birmingham Judges which he pronounces to be "in bad taste," and he charges them with "having no confidence in any judges but their own, and blaming the conduct of every show not subservient to their mandates." To say nothing of this being a pure libel on a body of gentlemen numbering among them, according to "BRAHMA's" admission, several "very honourable" men, how does this charge agree with the statement "BRAHMA" set out with, that the dissentients did not exceed some twenty, at most, clamorous individuals, who, by the pertinacity of their representations, make up for the paucity of their numbers? One statement contradicts the other, and both cannot be true. And then as to the excuses made for the Judges, through the multiplicity of their duties preventing their performing them with due care, I have only to say that the Judges ought to be held responsible for their decisions, and that if they undertake duties under circumstances which preclude the due performance of them, the blame rests on their shoulders. Whether from this cause or from incompetence, it is notorious that the decisions at Birmingham have caused very wide-spread dissatisfaction, and it is equally certain that unless it be brought under a different régime it will be superseded by other shows at which exhibitors may calculate on receiving more even-handed justice. —EXHIBITOR.

THE arguments by "BRAHMA," in THE JOURNAL OF HORTICULTURE, of December 19th, extort revival. This correspondent proceeds to say, "The truth is, the prizes at Birmingham Show are so important to all, and such a source of profit to many, that they cannot bear to lose." This statement by "BRAHMA" is quite incapable of dispute, still it must not be overlooked by amateurs, that though these remarks bear with all possible force as directed against exhibitors alone, it is surely at least equally severe and cutting, if applied to the interest of parties by whom poultry is supplied to competitors at Birmingham, for, as "BRAHMA" himself asserts, "such a source of profit to many, they cannot bear to lose." A truth, no doubt. It is evident that the triple anecdotes of the unpopular Pasha, Mr. Primrose, and Solomon Eagle, are shrewdly introduced by "BRAHMA," to serve as a kind of private back-way, by which this year's almost universal complaints of the decisions at Birmingham may be eluded or countercharmed.

"BRAHMA" states, "Four or five discontented in a large class congregate together, and loudly make their complaints." Had "BRAHMA" not purposely turned a deaf ear to such complaints at the Birmingham Show, he must have witnessed a striking illustration of his old proverb, "Let the losers laugh, for the winners are sure to do so;" for the winners at Birmingham, certainly in many instances, not only "laughed" in their sleeves, but blushed also at their unexpected and unmerited success, supporting their sincerity in so doing, by not only offering their own prize birds in barter for those in the same class that were unnoticed, but eventually a few sovereigns to boot, to induce still further the much-coveted exchange.

Such incongruities, wherever occurring, will always make losers laugh, and winners also; but it is the laugh of irony, distinct from approval. "BRAHMA" again spontaneously assures your readers, "he attends few shows, but has often remarked, when he has been at one, that the complaints heard all day long proceeded always from the same people." That "the complaints always proceed from the same people," when he has been at one show, is quite a mistake, so far as Birmingham is this year concerned, for numbers who have hitherto been among the greatest devotees of the Bingley Hall decisions, were ranked among the foremost to complain. "BRAHMA" also assures us, that "he is no exhibitor himself, and tries to stand aloof from all influence."

It would be most unjust and ungrateful not to give the fullest credit to this statement; for I believe not a single Birmingham exhibitor ever for a moment assumed "BRAHMA" was an exhibitor, any more than, as under the signature of "BRAHMA," they would conclude he was a fowl; but all are glad to learn "he tries to stand aloof from all influence," and is thus a supporter of—FAIR PLAY.

YOUR correspondent, "A COUNTRY CURATE," has not put the case so strongly as he might have done with regard to the totally inadequate number of judges engaged at Birmingham. It is generally understood that two of them took the Game and Game Bantam classes, and that the other three took the remainder. Now, if that were so, the gentlemen who judged the first-mentioned classes had to inspect fifty-five pens per hour, even allowing them nine hours of daylight, and no time for refreshment, but as, in point of fact, it is only light from 8 A.M. to 4 P.M.—that is to say, light enough properly to examine fowls in pens, it is evident that the Judges must have judged upwards of sixty pens per hour for eight hours, a rate of inspection which, considering the great competition at such a show, no two men living could fairly make, however competent they might be as poultry judges.

But what these gentlemen accomplished is as nothing compared with the astounding labours of the other three, for they, having had 1179 pens to judge, must have inspected—that is, "carefully examined," 147 pens per hour for eight hours without intermission. This gives about twenty-four seconds for a careful inspection of each pen. Need more be said? Can we wonder that the best pen of Cochins were unnoticed? Is it surprising that such a blunder as Mr. Fowler speaks of was made in the Goose class? Is it not perfectly amazing that these poor over-worked gentlemen managed to make a satisfactory award in any class? In short, is it to be wondered at that gentlemen who go to great expense in getting up fowls for exhibition, in paying entry fees and carriage of their birds, are indignant at the way in which they have been treated by the Birmingham Council?

I have nothing to say against the Judges individually; indeed, with the exception of Mr. Baily, whom I conscientiously believe to be a thoroughly upright man, they are all strangers to me. I cannot help thinking, however, that after what took place last year with regard to certain Game-fowl awards, the Birmingham Council would have used a wise discretion if they had substituted some other arbitrator for one of their Game-fowl judges. It was evident that there were ugly circumstances connected with the real ownership of the fowls, as to which the quarrel I refer to took place, which were never cleared up to the satisfaction of anybody, and I cannot think that under these circumstances the appointment of that gentleman to judge again this year, was calculated to inspire with confidence the supporters of the Birmingham Show.—P.

MANCHESTER EXHIBITION OF POULTRY AND PIGEONS.

THE Belle Vue Show, held annually at the Zoological Gardens, Manchester, by the Messrs. Jennison, becomes year by year more and more popular. On the present occasion the increase in the number of entries was beyond all precedent, and everything connected with this year's Show augurs well for even a still greater development in future years. That the Messrs. Jennison well deserve such success no one can dispute; for, being accustomed to the care of living specimens of their own in the gardens, the very first symptom of any kind of ailment in any of the valuable specimens temporarily committed to their management catches their well-practised eye, and we can ourselves, as eye-witnesses, testify to the fact that time, trouble, and expense, are not in any case spared to put all right again. We are quite sure that but for this commendable practice, more than one

pen of highly valuable poultry, received in a suffering condition at the doors, could not by any possibility have reached the owners again alive. We cannot forbear here to digress to suggest more careful management by the railway companies, during transit, of valuable exhibition poultry, as though such companies may be, of course, legally compelled to "pay for" any loss or damage occurring through the negligence of their officials to such poultry, it by no means follows that any pecuniary compensation places owners in the same position as though their poultry had remained uninjured; for, to our own knowledge, it has repeatedly occurred that the loss of poultry, brought together with great care and outlay, has involved the loss of very many pounds in prize money throughout the exhibition season, besides the absence of those far more covetable trophies of success, plate prizes. These remarks are suggested from the fact that two hampers of poultry were delivered at the exhibition with the inmates all killed, having evidently been worried to death during transit by a dog. The folly of placing strange dogs, even if chained, within reach of poultry baskets, the generosity of people would have thought evident to even the most obtuse railway official, but it appears that even this gross neglect can occur by rail to the great vexation of all parties concerned. Messrs. Jennison at once returned these unfortunate specimens with a letter detailing the miserable circumstances under which they came to hand, and we cannot but express the hope that the knowledge of these facts may surely tend to induce plans which will in future prevent the possibility of any such occurrences as consignments of exhibition fowls being worried to death by dogs taking place on the railway.

Our remarks on the Show must be general. In *Dorkings* the display was uniformly excellent, and throughout the whole of the classes decided improvement was manifest, even at the first glance. Lady Holmesdale was a heavy prize-taker, and the condition in which her ladyship's birds were exhibited was faultless. The class for single *Dorking* cocks was undoubtedly one of the best that has been seen at any exhibition for years past, nor was the class for pairs of hens of this breed less deserving. We may just cursorily notice that we observed some very good *Dorkings* and also *Cochins* that had been recently washed, managed so badly that the feathers, having dried, appeared as though absolutely pasted together, from the soap not having been cleaved away. This may prove, perhaps, a serviceable hint to owners practising future ablutions. It may be as well to mention that in washing *White Cochins* the use of soda in the water brings out that objectionable yellow tinge so observable, under bad management, in the hackles, saddles, and backs of the cocks, and which, once established, nothing but the production of new feathers can rectify. Of course in *Buff* or *Partridge-coloured* birds the effects are not observable, but as soda in all cases takes away the oil from the feathers, fowls so washed always become soon dirty again, besides assuming a dullness of plumage by no means calculated to add to their attractiveness. In *Cochins*, Captain Heaton had it almost all his own way, exhibiting his stock to great advantage. Some marvelously good specimens of *Buff Cochins* were also exhibited by Mr. Charles Jennison, but "not for competition," their owner observing most frankly that "nothing should induce him to compete for a prize at any show under his own management." It seemed a matter of regret to pass such birds unnoticed, but there was no alternative, and the honourable feeling suggestive of so much self-denial cannot fail to meet with the approval of those parties competing at Manchester. The class for *Cochin* cocks was most excellent.

In *Spanish* fowls the display was far beyond the average, and, as a whole, they were shown in first-rate feather.

In *Game* fowls the Show at Manchester was remarkably successful, and the condition of most of the pens so perfect as to leave but little margin for selection of prizes on that score. We regretted to see, however, many of the most striking pens at first sight imperfect in the feet, a fault altogether so inexcusable in *Game* fowls that every other perfection of quality cannot make up for it, nor justify their appearance in the prize list, consequently they were passed over.

The *Game Bantams* were so numerous as to make a principal feature of the Show, and so great was the competition that the prizes were far more broadly sown than customary. There were some exquisite *Game Bantam* hens shown; but we cannot guard exhibitors too strongly against showing hens with white ears—it is a fatal objection, and seems to be now assuming a far more general form than a few years back. By a little careful attention in mating the parent birds this objection is easily avoided, and just at this time the hint may therefore prove most opportune, as affecting the offspring of 1866. The *Sebright Bantams* seem quite failing as to quality and numbers all through the kingdom, but at the Manchester Show we noticed some excellent specimens of the *White Booted Bantams*, and also of those popular pets, the *Cochin Bantams*.

Mr. Jennison made his usual display of ornamental water fowls, exhibited in a state of health and plumage that takes every observer by surprise. They consisted of *Barnacle Geese*, *Brent Geese*, *Langling Geese*, *Pintails*, *Widgeon*, *Garganies*, *Shell Ducks*, *Teal*, and several pens of exquisitely-feathered *Carolina Ducks*.

The attendance of visitors was a complete success, as was the Show altogether. The Music Hall at Belle Vue Gardens is decidedly the best building in the kingdom at which poultry shows are now held. Although a thousand pens were shown, each one was on the same level tier, each lot of birds rejoiced in the same amount of light, and yet

there was room and to spare. In fact, the hall would, with but little extra management, accommodate fully two thousand pens, and yet leave the avenues double the width of those met with at our principal shows—a feature adding, in the present day, quite as much personal comfort to lady visitors as ample room for the public does to the multitude of the stock exhibited.

That the Manchester Show is taking very rapid strides to the front is a fact that this year's meeting demonstrates beyond contradiction; and most deservedly do the Messrs. Jemison hold their present popularity, for, courteous alike to every one, they are only too anxious to give every proper consideration to any hint that may be given them without favour, feeling, or party spirit, if offered them as suggestive of any future improvement in their meetings. Under such favourable circumstances, added to a prize schedule that will be again the subject of careful revision and extension as to future meetings, the Manchester Poultry Show cannot fail to fully sustain the reputation it now so worthily holds with all exhibitors of poultry and Pigeons.

SINGLE COCKS.

DORRINGS (Coloured).—First, Viscountess Holmesdale, Linton Park, Staplehurst, Kent. Second, H. Lingwood, Barking, Needham Market, Suffolk. Third, J. Elsworth. Fourth, A. Fenton, Crumble Hall, Rochdale. Highly Commended, W. Cople; Sir St. G. Gore, Bart., Hopton Hall, Warks-worth, Derbyshire; W. Farr, Patricroft, Manchester. Commended, T. Burgess, Burleydam, Whitechurch, Salop.

SPANISH.—First, H. Lane, Milk Street, Bristol. Second, A. Fenton, Crumble Hall, Rochdale. Third, D. Parsley, Bristol. Highly Commended, J. Hardie; N. Cook; W. Rouse, Park Street, Bristol; G. Bridle; E. Jones, Clifton. Commended, W. R. Bull, Newport Pagnell; E. Jones; A. Heath, Calne.

COCHIN-CHINA (Cinnamon and Buff).—First, Capt. H. Heaton, Lower Broughton, Manchester. Second, J. Nelson, Heaton Mersey, Manchester. Third, R. White, Ironhall Park, Sheffield. Fourth, G. Fell, Springfield, Warrington. Highly Commended, J. Nelson; H. Mapplebeck, Birmingham; H. Tomlinson, Balsall Heath Road, Birmingham; H. Bates, Yardley, near Birmingham. Commended, Capt. H. Heaton.

COCHIN-CHINA (Brown and Partridge-feathered).—First and Second, Capt. H. Heaton. Third, H. Bates, Vintage House, Yardley, near Birmingham. Highly Commended, J. Elliott, Leigh, near Manchester; Capt. H. Heaton; R. J. Wood, Chorley; J. Stephens, Walsall. Commended, E. Tudman, Ash Grove, Whitechurch, Salop.

COCHIN-CHINA (White).—First, R. Chase, Tyndall Street, Balsall Heath, Birmingham. Second, Rev. F. Taylor, Keastwick, Kirby Lonsdale. Highly Commended, Capt. H. Heaton.

BRAHMA POOTRA.—First, H. Lacy, Helden Bridge, Second, J. K. Fowler, Prebendal Farm, Aylesbury. Third, T. Statter, Stand, Manchester. Highly Commended, W. Hargreaves, Bacup, near Manchester.

POLISH.—First, E. Smith. Second, H. Beldon, Goltstock, Bingley. **GAME (Black-breasted Reds).**—First, M. W. Stobart, Second, E. C. Gilbert, Penkridge, Stafford. Third, C. W. Brierley, Middleton, near Manchester. Highly Commended, J. Hardie; Sir St. G. Gore, Bart. Commended, Sir St. G. Gore, Bart.

GAME (Brown and other Reds, except Black-breasted).—First, C. W. Brierley. Second, Sir St. G. Gore, Bart. Third, T. Statter, Stand, near Manchester. Highly Commended, J. Fletcher, Stoneclough. Commended, T. Burgess, Burleydam, Whitechurch.

GAME (except Black-breasted and other Reds).—First, J. Halsall, Ince, Wigan. Second, J. Fletcher. Third, Sir St. G. Gore, Bart. Highly Commended, P. Norbury.

HAMBURG (Black).—Prize, C. Sidwick, Keighley. Highly Commended, R. Battersby.

HAMBURG (Golden-pencilled).—First, T. Burns, Abram, near Wigan. Second, S. & R. Ashton, Mottram. Third, T. Wrigley, jun.

HAMBURG (Silver-pencilled).—First, Sir St. G. Gore, Bart. Second, J. Robinson.

HAMBURG (Golden-spangled).—First, N. Marlow, Denton. Second, J. Wright, Lysonby, Melton Mowbray. Third, W. Kershaw. Highly Commended, J. Mellor; Sir St. G. Gore, Bart. Commended, J. Mellor.

HAMBURG (Silver-spangled).—First, Rev. W. Serjeantson, Acton Burnell Rectory, Shrewsbury. Second, J. Fielding. Highly Commended, Sir St. G. Gore.

GAME BANTAMS.—First, R. Hawkeley, jun. Second, J. Crossland, jun., Wakefield. Third, A. Fenton.

DORRINGS (Coloured).—First, Viscountess Holmesdale. Second, T. Statter, Stand, near Manchester. Third, H. Lingwood, Barking, Needham Market. Fourth, Sir St. G. Gore, Bart., Hopton Hall, Derbyshire. **HENS.**—First, Viscountess Holmesdale. Second, Miss F. S. Arkwright, Etwell Hall, Derby. Third, W. Cople, Highly Commended, J. Holme, Knowsley, near Prescot; W. Harvey, Bacup, near Manchester. Commended, A. Fenton, Crumble Hall, Rochdale; Mrs. F. S. Arkwright; J. K. Fowler, Prebendal Farm, Aylesbury. **CHICKENS.**—First, Sir St. G. Gore, Bart. Second and Fourth, Viscountess Holmesdale. Third, J. Hardie. Highly Commended, C. Cork, Shoreham. Commended, A. Fenton; J. Longland, Grendon, Northampton; Miss Davies, Chester; J. G. Pearson. **PULLETS.**—First, Viscountess Holmesdale. Second and Third, Miss Davies, Chester. Highly Commended, J. G. Pearson. Commended, Mrs. Dale.

DORRINGS (White).—First, J. Robinson, Vole House, Garstang. Second, H. Lingwood, Lymington, near Exeter. Third, J. Robinson.

SPANISH.—First, Viscountess Holmesdale. Second, E. Jones, Clifton. Third, E. Brown. **HENS.**—First, E. Jones. Second, A. Fenton. Highly Commended, J. Thresh. Commended, P. H. Stevens; W. Harvey. **CHICKENS.**—First, Viscountess Holmesdale. Second, D. Parsley, Bristol. Third, Miss Davies, Chester. Highly Commended, E. Jones, Clifton. Commended, Lady L. de Pennant, Peirny Castle Bangor. **PULLETS.**—First, W. Rouse, Bristol. Second, E. Jones, Clifton.

COCHIN-CHINA (Cinnamon and Buff).—First, Capt. H. Heaton. Second, J. Cattell, Lime Villa, Edgbaston. Third, Capt. H. Heaton. Commended, H. Tomlinson, Balsall Heath Road, Birmingham; H. Bates. **HENS.**—First, J. Elliott, Leigh near Manchester. Second, H. Tomlinson. Third, Capt. H. Heaton. Highly Commended, Capt. H. Heaton; W. A. Taylor, Turner Street, Manchester; C. W. Brierley. Commended, G. Fell, Springfield, Warrington. **CHICKENS.**—First, H. Mapplebeck, Birmingham. Second, G. Fell. Third, J. Nelson, Heaton Mersey, near Manchester.

PULLETS.—First and Second, Capt. H. Heaton. Third, Rev. C. Spencer, College House, Atleborough. Highly Commended, A. Fenton, Rochdale; G. Fell; Rev. C. Spencer. Commended, Rev. C. Spencer.

COCHIN-CHINA (Brown and Partridge Feathered).—First, Capt. Heaton. Second, E. Tudman, Whitechurch, Salop. **HENS.**—First, Capt. H. Heaton. Second, J. Horrocks, Tonge, near Middleton. Highly Commended, E. Tudman. **CHICKENS.**—First, "Cactus." Second, Capt. H. Heaton. Third, J. Horrocks. Highly Commended, E. Tudman. **PULLETS.**—First, E. Tudman. Second, Capt. H. Heaton. Highly Commended, J. Horrocks; E. Smith, Middleton, near Manchester.

COCHIN-CHINA.—First, Rev. F. Taylor, Keastwick, Kirby Lonsdale. Second, F. W. Zarhorst, Belleville, Donnybrook, Ireland. Commended, G. Lamb.

BRAHMA POOTRA (Light).—**CHICKENS.**—First, E. Pigeon, Lymington, Exeter. Second, J. Clarke, Chiswick Mall. Commended, J. Pares, Chilton Hall, Chertsey.

BRAHMA POOTRA (Dark).—**CHICKENS.**—First, R. W. Royle, Oatthorn House, Bray. Second, T. Bonifet, Houghton Lane, Preston. Third, H. Lacy, Lacy House, near Helden Bridge. Highly Commended, H. Lacy; J. K. Fowler, Prebendal Farm, Aylesbury. Commended, C. Cork, Shoreham; F. Powell; T. Statter.

POLISH (any variety).—First, H. Beldon, Goltstock, Bingley, Yorkshire. Second, E. Smith, Tonge, near Middleton. Highly Commended, H. Carter, Uppertone, Holmfirth.

GAME (Black-breasted Reds).—First, M. W. Stobart, Middleton-One-row, Darlington. Second, J. Fletcher, Stoneclough, near Manchester. Third, S. Matthew, Chilton House, Stowmarket. Fourth, F. J. Astbury. **CHICKENS.**—First, J. H. Williams, Welshpool. Second, J. Halsall, Ince, near Wigan. Third, J. Holme, Knowsley, near Prescot. Fourth, H. Bertram.

GAME (Brown and other Reds, except Black-breasted).—First, J. Fletcher, Stoneclough, near Manchester. Second, J. Smith, Grantham. Third, T. West, St. Ann's, Eccleston, St. Helen's. **CHICKENS.**—First, W. Gamon, Thornton-le-Moors. Second, J. Linnell, Anstey, Coventry. Third, T. Statter. Fourth, R. Swift, Southwell, Notts.

GAME HENS (Black-breasted and other Reds).—First, E. Aylkroyd, Gillington Road, near Bradford. Second, Mrs. Hay, The Cottage, Sandbury, Derby. Third, J. Smith. Highly Commended, T. West. Commended, C. W. Brierley. **CHICKENS.**—First, Messrs. Parkinson & Field, Boulton-le-Fyde. Second, G. Clements, Birmingham. Third, T. Burgess, Burleydam, Whitechurch. Highly Commended, W. Gamon; J. B. Lucas. Commended, Mrs. Hay; J. Fletcher; J. Wood, Moat House, Wigan; H. Bertram.

GAME (Duckings and other Greys and Blues).—First, Sir St. G. Gore, Bart. Second, J. H. J. Hall. Third, E. Aylkroyd. **CHICKENS.**—First, J. Fletcher. Second, T. Wakefield, Golborne, Warrington. Third, R. Tate, Green Road, Leeds.

GAME (White and Piles).—First, J. Fletcher. Second, Sir St. G. Gore, Bart. **CHICKENS.**—First, J. Sunderland, Halifax. Second, T. West.

GAME HENS (except Black-breasted and other Reds).—First, J. Firth, Halifax. Second, Mrs. C. W. Brierley.

HAMBURG CHICKENS (Black).—First, R. F. Goodwin, Middleton. Second, J. Jackson, Bury. Highly Commended, R. Battersby; C. Sidwick; J. Mellor, Kitchenfold, Slaithwaite, Yorkshire.

HAMBURG (Golden-pencilled).—First, J. Smith. Second, F. Pittis, jun., Newport, Isle of Wight. **CHICKENS.**—First and Second, T. Wrigley, jun. Third, Sir St. G. Gore, Bart. Commended, F. Pittis, jun.; W. Farr, Patricroft, near Manchester.

HAMBURG CHICKENS (Silver-pencilled).—First, J. Robinson. Second, Sir St. G. Gore, Bart. Third, J. Fielding, Newchurch, near Manchester. Highly Commended, J. Lanceshire. Commended, A. K. Wood, Burnside, Kendal.

HAMBURG CHICKENS (Pencilled).—First, T. Wrigley, jun. Second, F. Pittis, jun. Commended, W. Pierce.

HAMBURG (Golden-spangled).—First, Sir St. G. Gore, Bart. Second, J. Buckley, Taunton, Ashton-under-Lyne. Third, J. Roe. Highly Commended, N. Marlow; W. Kershaw, Wood, near Manchester; W. Farr.

HAMBURG CHICKENS (Silver-spangled).—First and Third, J. Fielding. Second, Sir St. G. Gore, Bart. Highly Commended, J. Jackson; A. K. Wood. Commended, J. Lanceshire.

HAMBURG HENS (Spangled).—First, W. A. Hyde, Ashton-under-Lyne. Second, J. Fielding. Highly Commended, J. Roe; N. Marlow; J. Wright; A. K. Wood. **PULLETS.**—First, J. Andrews, Ashton-under-Lyne. Second, N. Marlow.

GAME BANTAMS (Black-breasted and other Reds).—**CHICKENS.**—First, Rev. G. Rayner, Brentwood, Essex. Second, J. Hilton. Third, J. W. Kellaway. Fourth, B. Parsons.

GAME BANTAMS (any other Variety).—**CHICKENS.**—First, R. Tate. Second, W. S. Forest, Greenhithe, Kent. Third, Mrs. C. W. Brierley.

BANTAMS (any Variety except Game).—First, T. Boncher, Birmingham (Buff Cochins). Second, C. W. Brierley. Third, Messrs. J. & A. Briggs, Rowden, near Leeds. Commended, P. W. Story (White-feathered Legged Bantams).

DUCKS (White Aylesbury).—First, J. K. Fowler, Prebendal Farm, Aylesbury. Second, E. Leech, Rochdale. Third, H. Jones.

DUCKS (Rouen).—First, Sir St. G. Gore, Bart. Second, A. Fenton. Third, T. Statter. Fourth, J. Holme.

DUCKS (Black East Indian).—First, Rev. W. Serjeantson, Shrewsbury. Second, T. Wadswley, Chester.

DUCKS (Any other Variety).—First, T. H. D. Bayley, Biggleswade, Beds. (Brown Call Ducks). Second, T. Statter (Wild Ducks).

ORNAMENTAL WATER FOWL.—First, Second, and Third, J. Jennison, Bellevue, Manchester.

GESE (White).—First, Messrs. J. & W. Rostron, Leven-hulme. Second, A. Fenton. Third, E. Shaw, Plus Wilmot, Oswestry.

TURKEYS.—First, E. Leech, Rochdale. Second, Mrs. A. Guy, Eaton, Grantham. Third, C. P. Ackers. **POLLS.**—First, J. Smith, Grantham. Second, E. Leech. Third, Miss Davies, Chester.

EXTRA STOCK.—First, E. Pigeon, Lymington, near Exeter (La Fleche). Second, W. Hargreaves, Dark Brahmans. Third, F. W. Zarhorst, Sultans. Highly Commended, Mrs. E. Haig (Magpie Turfans); W. Chadwick (Blue Andalusian).

PIGEONS.

POWERS.—First and Second, A. P. Leite, Oxford Road, Manchester.

POWERS (White).—First and Second, A. P. Leite.

POWERS (Black).—First, A. P. Leite. Second, C. Cole.

CARRIERS (Black).—Cock.—First, T. Colley, Sheffield. Second, A. P. Leite. Third, M. Hedley, Redhill, Surrey. Highly Commended, F. Else, Bayswater. *Hen.*—First, M. Hedley. Second and Highly Commended, A. P. Leite.

CARRIERS (any other Colour).—Cock.—First, T. Colley. Second, A. P. Leite. Third, F. Else. *Hen.*—First, A. P. Leite. Second, T. Colley. Commended, A. P. Leite.

CARRIERS (any other Colour).—First and Second, T. Barnes, Birmingham. Third, G. W. M. Dawson, Birmingham. Commended, F. Else.

DRAGONS.—First, J. Percival, Peckham Rye. Second, W. J. Corbridge. Third, F. Smith. Commended, G. Wood; T. H. Ridpath, Rusholme, Manchester.

JACOBS (any Colour).—First and Second, J. T. Lawrence, Moffat. Third, J. B. Pinder. Very Highly Commended, F. Esquilant. Highly Commended, J. T. Lawrence; T. H. Ridpath.

NUNS.—First, C. Bulpin, Bridgewater. Second, F. Else. Third, H. Yardley, Market Hall, Birmingham.

PIGEONS.—First and Second, T. D. Green, Safron Walden. Third, E. Pigeon. Commended, A. P. Leite.

BARBS.—First and Second, A. P. Leite. Third, M. Hedley, Redhill.

EBBS (any Colour).—First, E. M. Eggar, Manchester. Commended, W. Massey.

TURBITS.—First, H. Mapplebeck, Birmingham. Second, E. E. M. Roys, Greenhill, Rochdale.

OWLS.—First and Second, J. Fielding, jun. Third, A. P. Leite. Highly Commended, A. P. Leite.

TRUMPETERS.—First, A. P. Leite. Second, S. A. Taylor, Wheeler Street, Lozells, Birmingham. Third, F. Else.

FANTAILS.—First, F. Else. Second, H. Yardley. Highly Commended, F. Else.

ALMOND TUMBLERS.—First and Second, A. P. Leite. Third, E. M. Edgar. Highly Commended, J. Fielding, jun.

ALMOND TUMBLERS (bred in 1865).—First, J. Fielding, jun.

TUMBLERS (any other Variety).—First, L. Glassey, Rochdale. Second, A. P. Leite. Highly Commended, A. P. Leite. Commended, J. Percival.

BEARDS.—First and Second, W. H. C. Oates, Besthorpe, Newark.

BALDS.—First, F. Esquilant, Erixton. Second, F. B. Walker.

ANY OTHER VARIETY.—First, F. Broemel, Ludgwell, Kent (Siberian Toed Pigeons). Second, A. P. Leite (Laced Fantails). Third, A. P. Leite (Swiss Pigeons). Highly Commended, J. Dyson (White Crowned Pigeons, and Passenger Pigeons). Commended, Countess of Derby (Isabells); H. Yardley.

RABBITS.

BLACK AND WHITE.—First, E. V. Ridpath, Rusholme. Second, H. Handford, Wilford, Notts.

YELLOW AND WHITE.—First, W. Stelfox, Greenheys. Second, P. Eden.

TORTOISESHELL.—First, H. Handford. Second, E. V. Ridpath.

GREY AND WHITE.—First, A. Firth, Hyde, near Manchester. Second, G. F. Jones.

SELF-COLOUR.—First, W. Stelfox. Second, P. Eden.

HEAVIEST WEIGHT.—Prize, H. Handford.

FOREIGN RABBITS.—First, J. Buchanan, Port Vale, Hertford (Angora). Second, B. Robinson (Angora).

JUDGES.—Poultry: E. Hewitt, Esq., Eden Cottage, Sparkbrook, Birmingham, and R. Teebay, Esq., Fulwood, near Preston, judged the Dorkings, Spanish, Cochon-China, Brahma Pootra, Polish, and Hamburg classes; and W. B. Tegetmeier, Esq., Muswell Hill, London, and Mr. John Douglas, Clumber Park, Worksop, judged the Game Fowls, Ducks, Geese, Turkeys, Extra Stock, and Bantams. *Pigeons:* Harrison Weir, Esq., Peckham, London; Dr. Cottle, Cheltenham.

Rabbits: Mr. Edward Owen, London.

NORTH BRITISH COLUMBIAN SOCIETY'S SHOW.

THIS Society's seventh grand annual exhibition and competition of fancy Pigeons, open to all competitors, was held in the Trades' Hall, Glasgow, on the 22nd and 23rd of December. The entry numbered 450 pens from all parts of the United Kingdom, being an increase of upwards of 120 pens over the number exhibited last year. The Powder classes were the great feature of the Show; young birds being shown in pairs in six classes, for which a silver medal, or £2 2s., was offered, and mustering thirty-eight pens, while old birds, shown singly, numbered no less than 192 pens, and had fourteen classes allotted to them. The whole were exhibited in the capital circular pens belonging to the Society; each bird not only having the advantage of a small block of wood on which to perch, but the food and water being placed on the outside in the space between each pen, the comfort of the specimens was secured in every respect.

Another remarkable feature was that scarcely an inferior bird appeared, and there were not half a dozen bare-shinned or thinly-covered-limbed Powders in the whole collection. It will be seen by the prize list that the greater portion of the prizes in Powders were gained by fanciers across the Border, for, with the exception of Mr. Montgomery, of Belfast, a most formidable opponent, and who nobly held his own in such a severe competition, very few of the honours fell to English fanciers, and, to compete successfully with Scotchmen, English fanciers will have to bestir themselves. We may mention that Mr. Leite's birds were not sent. The entire arrangements of the Show were admirably carried out by the Committee and by Mr. Ruthven, the Hon. Secretary, who left nothing wanting for the comfort of the various specimens.

In the first class for the best pair of Black Pied *Porters*, a silver medal, or £2 2s., was offered by Mr. James Muir; the medal was awarded to an even pair belonging to Mr. Ure. Mr. Montgomery exhibited the best bird in the class, a very handsome cock, receiving

very high commendation, but the bird was very indifferently accompanied. For a pair of Whites, bred in 1865, Mr. Sanderson won the medal, presented by himself, with a stout pair, in a rather weak class. Young Blues were a better lot, Mr. Ure gaining the medal, presented by Mr. Geddes, with a capital pair, after a most severe contest with Mr. Ruthven, whose birds were very highly commended. In the similar class for young Reds the competition was keen, the cock in Mr. Montgomery's pen being remarkably fine. Mr. M'Farlane, however, secured Mr. Hawkins's medal with a capital, well-matched pair. Young Yellows were not numerous, but Mr. Frame's medal was won by an unusually good pair, which speedily changed ownership at £21. Young Meals were an average lot, good in style and symmetry, feather alone being the drawback; Mr. Moon securing Mr. Maclean's medal with good birds. Single Black cocks numbered eleven, and formed, perhaps, the best collection ever brought together; Mr. Montgomery's first-prize bird being exquisite in colour, very lengthy, and finely shaped, well deserving his position; the competition, however, was exceedingly close—indeed, at least half of the birds were worthy of prizes. White cocks were both numerous and of very great excellence, the champion cock at Glasgow last year again standing first, and although he was unquestionably clear of his competitors, being shown in marvellous condition, no less than seven other birds received notice, which they well merited. Blue cocks mustered twenty-seven, and were a slow of themselves, such as was never seen before, there being scarcely an inferior bird in the lot. Mr. Ure's first-prize bird was remarkable for fine symmetry, colour, and length, Mr. Lightbody's second-prize one having a slight advantage in length, but not being quite equal in shape. Mr. Stuart ran a very close third with a capital representative, and many of the others were well worthy of a position. Red cocks were a large entry, the prize birds being especially noticeable, but an improvement in colour would be a great desideratum. Mr. Wallace held his position of last year in a splendid class. Yellow cocks were very fine, and the first-prize Mealy cock was scarcely inferior to any other exhibited, except in colour. In Powder cocks, any other marking, a very good Checker and White Splash took the prizes. This class also contained a veritable 20-inch-feathered bird, a Blue and White Splash, but disproportionate in limb. Black hens were capital, and especially good in colour, as well as shape and length, most of the competitors deserving notice. White hens were also well represented, Mr. Sanderson winning first with a first-class hen, which was immediately claimed at £10 10s.; the competition was very good. Blue hens were very fine, Mr. Lightbody repeating his last year's victory with the same hen, a bird of immense length and fine style. Several hens deservedly received notice, but we thought the Judges rather sparing of their favours. Red hens were a nice lot, more particularly the placed birds. Yellow hens we thought decidedly the greatest improvement in the Show, the class being large, and fast approaching the standard of the other colours. Mr. Ure's wonderful hen again had the first position, and also gained Mr. Moon's silver medal for the best Powder in the Show. The classes for Mealy hens, and hens any other marking, each brought really first-class competitors, Mr. Ruthven's prize Mealy being speedily claimed.

For the best pair of Black *Carriers*, bred in 1865, Mr. Wallace offered a silver medal, and several good birds were sent, but some of the best were passed over as not answering the requirements of the class. Single Black Carrier cocks were very good; Mr. Colley, however, had an easy victory with an extraordinarily fine stout bird, while in the class for Black hens the same remarks are applicable to Mr. Else's splendid hen. Mr. Colley, however, won the oil portrait of the [most perfect] Carrier in the Exhibition with the Black cock. Young Dun Carriers were not very striking, and we fancied the relative sexes were not present in the best pen, which was passed over.

In *Short-faced Tumblers*, Mr. Fulton's first-prize Almonds and Black Mottles were particularly good, while Mr. Stuart's Kites and Agates, in the class allotted to them, were very fine.

Barbs were, as usual, only a weak class, Mr. Robinson's first-prize pair of Blacks completely outdistanced competition, and also gained the silver cup, value £5 5s., presented by a few English fanciers for the best pen in classes 23 to 31.

Pantouls were a capital class, the prizes being given to plain-headed birds; the first-prize pair were excellent in tail, and the second pair were remarkably small, and graceful in carriage.

Jacobins were an average lot, all colours being well shown.

In *Trumpeters* good Black Mottles were first, and Whites second; and in *Turbits* Mr. Thackray's medal pair were small, peaked-crowned Reds.

In *Owls*, Mr. Pickering's medal pair were particularly good foreign Whites, the best we have seen for some time, and good Blues (foreign) were second.

The prizes for Any other variety were awarded first to Swiss, second Blue Swallows, and third Blue Brunswicks.

EXTRA PRIZES.

Silver Cup, or £8.—G. Ure, Dundee.
Silver Cup, value £5 5s., for the best pen in classes 23 to 31 inclusive.—J. R. Robinson, Sunderland (Barbs).

Oil-painted Portrait of the most perfect Carrier in the Exhibition.—T. Colley, Sheffield.

Prize of Two Guineas, presented by James Haie, Esq., Glasgow, for the best pair of Owls.—R. Pickering, Carlisle.

Silver Medal, or £2 2s., presented by J. R. Rennards, Esq., for the best pair of Turbits.—J. Thackray, York.

Silver Medal, presented by William Moon, junr., Esq., Edinburgh, for the best Fowler hen, any colour.—G. Ure, Dundee (Yellow).

Silver Medal, or £2 2s, presented by James Muir, Esq., for the best pair of Black Pied Fowls, bred in 1865.—Medal, G. Ure, Dundee. Highly Commended, J. Grant, Corstorphine. Commended, W. Geddes, Glasgow.

Silver Medal, or £2 2s, presented by Matthew Sanderson, Esq., Edinburgh, for the best pair of White Fowls, bred in 1865.—Medal, M. Sanderson, Edinburgh. Highly Commended, R. H. Simpson, Newark. Commended, W. Moon, Edinburgh.

Silver Medal, or £2 2s, presented by John Geddes, Esq., for the best pair of Blue Pied Fowls, bred in 1865.—Medal, G. Ure, Dundee. Very Highly Commended, J. Ruthven, Glasgow. Highly Commended, T. Short, Glasgow; D. Stewart, Perth.

Silver Medal, or £2 2s, presented by Henry Hawkins, Esq., Belfast, for the best pair of Red Pied Fowls, bred in 1865.—Medal, J. M. Farlane, Tulleross, Glasgow. Very Highly Commended and Highly Commended, J. Montgomery, Belfast.

Silver Medal, or £2 2s, presented by J. H. Frame, Esq., Overton, for the best pair of Yellow Pied Fowls, bred in 1865.—Medal, G. Ure, Dundee. Highly Commended, G. Ure. Commended, T. H. Evans, London.

Silver Medal, or £2 2s, presented by George J. Maclean, Esq., Edinburgh, for the best pair Mealy Pied Fowls, bred in 1865.—Medal, W. Moon, Edinburgh. Very Highly Commended, G. W. Jeffrey, Ireland.

CLASS PRIZES, GIVEN BY THE SOCIETY.

POWTERS (Black).—First, J. Montgomery, Belfast. Second, G. Ure, Dundee. Third, M. Stuart, Glasgow. Highly Commended, J. Wallace, Glasgow; J. M. Farlane, Tulleross, Glasgow; J. Montgomery, Belfast.

POWTERS (White).—First, J. Montgomery, Belfast. Second and Third, J. Wallace, Glasgow. Very Highly Commended, M. Sanderson, Edinburgh; J. Ruthven, Glasgow; T. Short, Glasgow. Highly Commended, J. Thackray, York; R. Fulton, Deptford.

POWTERS (Blue).—First, G. Ure, Dundee. Second, W. Lightbody, Glasgow. Third, M. Stuart, Glasgow. Very Highly Commended, J. Montgomery, Belfast; M. Stuart, Glasgow; J. Wallace, Glasgow; D. Stewart, Perth.

POWTERS (Red).—First, J. Wallace, Glasgow. Second and Third, J. Montgomery, Belfast. Very Highly Commended, W. Geddes, Glasgow. Highly Commended, J. Montgomery, Belfast. Commended, J. Muir, Glasgow.

POWTERS (Yellow).—First and Third, G. Ure, Dundee. Second, J. Wallace, Glasgow. Very Highly Commended, G. J. Samuels, Manchester.

POWTERS (Mealy).—First, J. Montgomery, Belfast. Second, M. Stuart, Glasgow. Highly Commended, M. Sanderson, Edinburgh; G. Maclean, Edinburgh; W. Lightbody, Glasgow.

POWTERS (Any other marking).—First, J. Montgomery, Belfast (Checker). Second, G. Ure, Dundee (Splash). Highly Commended, M. Stuart, Glasgow.

POWTERS (Black).—Hens.—First, B. Arbuckle, Parkhead. Second and Third, M. Stuart, Glasgow. Very Highly Commended, J. Montgomery, Belfast.

POWTERS (White).—Hens.—First, M. Sanderson, Edinburgh. Second, J. Montgomery, Belfast. Third, G. Ure, Dundee. Very Highly Commended, M. Sanderson, Edinburgh. Highly Commended, J. Wallace, Glasgow.

POWTERS (Blue).—Hens.—First, W. Lightbody, Glasgow. Second, M. Stuart, Glasgow. Third, J. Montgomery, Belfast. Highly Commended, J. Wallace, Glasgow; J. Montgomery, Belfast.

POWTERS (Red).—Hens.—First and Third, G. Ure, Dundee. Second, J. Montgomery, Belfast. Very Highly Commended, J. Mitchell, Glasgow. Highly Commended, E. E. M. Boyd, Greenhill, Rochdale.

POWTERS (Yellow).—Hens.—First, G. Ure, Dundee. Second, T. H. Evans, London. Third, J. Wallace, Glasgow. Very Highly Commended, J. Montgomery, Belfast; G. Ure, Dundee; R. Fulton, Deptford.

POWTERS (Mealy).—Hens.—First, J. Ruthven, Glasgow. Second, G. White, Paisley. Highly Commended, J. E. Spence, Musselburgh.

POWTERS (Any other marking).—Hens.—First, W. Lightbody, Glasgow (Checker). Second, W. Geddes, Glasgow (Checker). Highly Commended, M. Stuart, Glasgow (Yellow-barred).

EXTRA PRIZE.—Silver Medal, or £2 2s, presented by James Wallace, Esq., Glasgow, for the best pair of Black Carriers, bred in 1865.—Medal, H. Martin, Glasgow. Very Highly Commended, T. Colley, Sheffield.

CARRIERS (Black).—First, T. Colley, Sheffield. Second, H. Hawkins, Belfast. Third, F. Else, London. Very Highly Commended, J. Wallace, Glasgow; G. Ure, Dundee.

EXTRA PRIZE.—Silver Medal, or £2 2s, presented by Daniel Stewart, Esq., Perth, for the best pair of Dum Carriers, bred in 1865.—Medal, J. Wallace, Glasgow. Very Highly Commended, G. Ure, Dundee.

CARRIERS (Dum).—First, T. Colley, Sheffield. Second, H. Martin, Glasgow. Third, F. Else, London. Highly Commended, G. Ure, Dundee.

CARRIERS (Black).—First, F. Else, London. Second, J. Kyle, Glasgow. Third, J. Wallace, Glasgow. Very Highly Commended, G. Ure, Dundee. Highly Commended, S. Sanday, Notts.

CARRIERS (Dum).—First, F. Else, London. Second and Third, G. Ure, Dundee.

CARRIERS (Any other colour).—First and Second, T. Colley, Sheffield.

EXTRA PRIZE.—Silver Medal, or £2 2s, presented by Fred. Elze, Esq., London, for the best pair of Short-faced Albion Tumblers, bred in 1865.—Medal and Highly Commended, J. Wallace, Glasgow.

SHORT-FACED TUMBLERS (Albion face).—First, E. Hilton, London. Second, J. B. Robinson, Sunderland. Third and Highly Commended, J. Ford, London.

SHORT-FACED TUMBLERS (Bottles).—First, R. Fulton, Deptford. Second, W. R. C. Oates, Notts. Third, F. Else, London.

SHORT-FACED TUMBLERS (Agates, Kites, or Self colours).—First and Second, M. Stuart, Glasgow. Third and Agates. Third and Highly Commended, J. Ford, London. Self colours. Commended, J. Ruthven, Glasgow (Agates).

EXTRA PRIZE.—Silver Medal, or £2 2s, presented by James Montgomery, Esq., Belfast, for the best pair of Barbs, bred in 1865.—Medal, W. Power, Belfast (Black).

BARBS.—First and Cup, J. R. Robinson, Sunderland (Black). Second, J. R. Reynolds, Helensburgh. Highly Commended, S. Sanday, Notts (Red). J. Kyle, Glasgow (Black); G. White, Paisley.

BANTAMS.—First, F. Else, London. Second, J. R. Robinson, Sander-

land. Highly Commended, T. Moon, Edinburgh; J. Wallace, Glasgow; G. Steel, Ayr.

JACONINS.—First, J. Sharp, Johnston (Yellow). Second, R. Pickering, Carlisle. Very Highly Commended, W. Nelson, Johnstone. Highly Commended, J. R. Robinson, Sunderland; C. J. Samuels, Manchester.

EXTRA PRIZE.—Two Guinea, presented by William Power, Esq., Belfast, for the best pair of Trumpeters, bred in 1865.—Medal, J. Prentice, Glasgow.

TRUMPETERS.—First, J. R. Robinson, Sunderland. Second, W. H. C. Oates, Notts. Highly Commended, F. Else, London.

TROTTERS.—First, Silver Medal or £2 2s, J. Thackray, York (Red). Second, J. R. Robinson, Sunderland. Highly Commended, H. Yardley, Birmingham; J. R. Reynolds, Helensburgh.

OWLS.—First, Silver Medal or £2 2s, R. Pickering, Carlisle. Second, J. Fielding, junr., Rochdale (Blue). Highly Commended, F. Else, London; J. Fielding, junr., Rochdale (White).

NESS.—First, F. Else, London. Second, W. Nelson, Johnstone. Highly Commended, R. Pickering, Carlisle.

COMMON TROTTERS.—First, J. Percival, London (Yellow Mottled). Second and Highly Commended, J. Sephton, Preston.

ANY OTHER BREEDS.—First, E. Pigeon, near Exeter (Swiss). Second, J. Percival, London (Swallow). Third, H. Yardley, Birmingham.

JUMPS.—T. J. Charlton, Esq., Bradford; E. L. Corker, Esq., Croydon; J. Miller, Esq., Glasgow.

WENTWORTH WOODHOUSE POULTRY SHOW.

THIS took place on the 21st and 22nd ult., when the following prizes were awarded:—

BORINGS.—First, Hon. F. C. H. Hawke, Wormley Park, near Pontefract. Second, J. Hattfield, Cottingham, Hull. Highly Commended.—Hurt, W. Harvey, Sheffield. *Chickens.*—First, W. Harvey, Second, J. White, Warley, Northallerton. Highly Commended, H. Saville, Rufford Abbey, Ollerton, Notts; Hon. W. H. W. Fitzwilliam, Wentworth-Woodhouse, Rotherham. Commended, Hon. F. C. H. Hawke.

COCHIN-CHINAS (except White).—First, E. Yearlley, Wisewood, near Sheffield. Second, W. Dawson, Hopton Mirfield. Highly Commended, R. White, Broomhall Park, Sheffield. Commended, E. Bemrose, Derby; W. Harvey.

COCHIN-CHINAS (White).—Prize, W. Dawson, Hopton Mirfield.

COCHIN-CHINAS (Any variety).—*Chickens.*—First, W. Wood, Sheffield (Buff). Second, R. W. Boyle, Bray, Co. Wicklow (Buff). Highly Commended, W. Dawson (Buff); Lady M. Thompson, Sheriff Hutton Park, near York (Partridge).

GAME (Reds).—First, C. Challoner, Steely, Worksop. Second, G. Westholme, Sheffield. Highly Commended, Lady Milton, Osberton, Worksop; F. Sales, Crowle, Lincolnshire; W. Bentley, Scholes-in-Cleckheaton.

GAME (Any other variety).—First, F. Sales, Crowle, Lincolnshire (Duckwing Grey). Second, G. Westholme, Sheffield (Guns Red). *Chickens.*—First, C. Trivice, Thurgoland, near Sheffield. Second, C. Challoner, Steely, Worksop. Highly Commended, Lady Milton, Osberton, Worksop (Black Red); W. J. Cope, Barnsley. Commended, Hon. W. H. Fitzwilliam, Wentworth-Woodhouse, Rotherham (Black Red).

SPANISH.—First, W. Harvey, Sheffield. Second, Messrs. Burch and Boulter, Sheffield. *Chickens.*—First, J. Threlk, Bradford. Second, W. Harvey, Sheffield. Highly Commended, T. Greenwood, Dewsbury.

POLANDS.—First, W. Harvey, Sheffield. Second, W. Sylvester, Hampden View, Sheffield. Extra Prize, Mrs. J. M. Proctor, Highly Commended, Messrs. Binchcliffe & Moody, Liphall Bank, Holmfirth; Mrs. J. M. Proctor, Hull; W. Sylvester.

HAMBURGS (Pencilled).—First, E. Yearlley, Wisewood, near Sheffield (Golden-pencilled). Second, W. Froggatt, Walkley, Sheffield (Golden-pencilled). Highly Commended, B. Oates, Owlerton, Sheffield (Silver-pencilled); T. Crookes, Owlerton (Golden-pencilled).

HAMBURGS (Spangled).—First, Hon. W. C. W. Fitzwilliam, Wentworth-Woodhouse, Rotherham (Silver-spangled). Second, S. Noble, Strickland Gate, Kendal (Silver-spangled). Highly Commended, W. W. Nicholls, Sale, Cheshire (Golden-spangled); W. Harvey, Sheffield; J. F. Liversidge, Newark, Notts (Silver-spangled).

GAME BANTAMS.—First, Hon. T. W. Fitzwilliam. Second, R. Dodge, Sharrow View, Sheffield. Highly Commended, E. B. Postans, Brentwood; Hon. T. W. Fitzwilliam. Commended, Hon. T. W. Fitzwilliam.

BANTAMS (Any other variety).—First, W. J. Cope, Barnsley (Pekin Bantams). Second, H. Woods, Clifton Park, Mansfield (Black Bantams) Highly Commended, W. Taylor, Hunslet, Leeds (Black Bantams); H. Saville, Rufford Abbey, Ollerton, Notts (Japanese Siskies); J. Walker, Halifax (Gold-laced); E. Hutton, Pudsey, near Leeds (Black Bantams) Commended, W. Taylor (White Bantams).

BRAHMS.—First, R. W. Boyle, Bray, Co. Wicklow. Second, Hon. W. C. W. Fitzwilliam. Highly Commended, W. Harvey. Commended, Hon. T. W. Fitzwilliam.

SINGLE COCKS.

GAME.—First, G. Westholme, Sheffield. Second, C. Trivice, Thurgoland, near Sheffield. Highly Commended, T. H. Mings, Sheffield, near Halifax; C. Challoner, Worksop; F. Sales; Hon. W. H. W. Fitzwilliam.

BORINGS.—First, W. Harvey, Sheffield. Second, O. E. Cresswell, Harworth Rectory, Hounslow, Middlesex. Highly Commended, E. T. Kell, Wetherby; H. Saville; Hon. W. H. W. Fitzwilliam.

GAME BANTAMS.—First, E. B. Postans, Brentwood, Essex. Second, Hon. W. C. W. Fitzwilliam. Highly Commended, T. C. Harrison, Hull; R. Cooke, Stavely, Chesterfield.

ANY OTHER VARIETY NOT PREVIOUSLY MENTIONED.—First, W. Wood, Sheffield (Malays). Second, H. Saville, Ollerton, Notts (Black Hamburg), Highly Commended, J. Davies, Huddersfield (Siskies); C. Sedwick, Kettleby, Black, Handborough; Mrs. Hurt, Aldersley, Derby. Commended, Hon. W. Eden, Cawley, Doncaster (Cape Currs).

DUCKS (Aylesbury and Rouen).—First, Hon. W. H. W. Fitzwilliam (Aylesbury). Second, Hon. F. C. H. Hawke, Wormley Park, near Pontefract (Rouen). Highly Commended, R. Massey, Hooper, near Rotherham (Aylesbury); W. Taylor, Hunslet, Leeds.

SELLING CLASS—First, Hon. W. H. W. Fitzwilliam (Black Red Game).
Second, T. C. Harrison, Hull (Brown Call).

SWEEPSTAKES FOR SINGLE COCKS.

GAME.—First, C. Challoner, Steely, Workop. Second, W. H. W. Fitzwilliam. Highly Commended, G. Wostenholme; R. Dodge, Sharrow View-Sheffield.

DORRING.—Prize, Hon. W. H. W. Fitzwilliam. Highly Commended, Hon. W. C. W. Fitzwilliam.

JUDGE.—Mr. Douglas.

HECKMONDWIKE POULTRY SOCIETY'S SHOW.

The fourth annual meeting of the above Society was held on the 26th of December. The morning gave promise of a fine day, but towards noon a few drops of rain fell, and when the Show was opened a smart shower came on, which for a time put a stop to the attendance of visitors. In consequence of the Manchester Show being so close at hand, the pens exhibited were not so numerous as last year; but the quality of the birds compensated for any lack of numbers, and most of them were in fine feather. The *Game* classes were the most numerous, and in the Black-breasted and Brown Red classes some excellent birds were shown. The Duckwings were good, so were the Blacks. The classes for *Bantams* contained some very good birds. In the Red and Duckwing classes several birds changed owners. The Black cock in the first-prize pen was sold for £5. In the *Hamburgh* classes there was not a single entry, a most singular case, as in this neighbourhood it formerly was rare to see a cottager keep anything but a "Pheasant or a Chitteprat." The other classes contained some good birds, but the competition was confined to a few pens in each class.

GAME (Black-breasted Red).—First, J. Beetham, Girtinton. Second, J. Vickerman, Chickensley.

GAME (Brown Red).—First, H. C. Mason, Drighlington. Second, J. Hodgson, Ewling Old Lane. Highly Commended, J. Ineson, Staincliffe. Commended, P. Greenwood, Liversedge.

GAME (Duckwings and other Grey and Blue).—First, J. Fell, Adwalton. Second, J. Spedding, Chickensley.

GAME (White and Pile).—First, H. C. Mason. Second, W. Whiteley, Liversedge.

GAME (Black and Brassy-winged).—First, G. Noble, Staincliffe. Second, J. Walshaw, Heckmondwike. Highly Commended, J. Ineson.

GAME BANTAM (Red).—First, G. Noble. Second, J. Elam, Heckmondwike.

GAME BANTAM (Duckwing).—First, I. Goodall, Heckmondwike. Second, J. Elam.

BANTAM (Black).—First, J. Parker, Heckmondwike. Second, J. Brook, Heckmondwike.

SPANISH (Black).—First, T. Greenwood, Dewsbury. Second, W. Whiteley, COCHIN-CHINA (Any colour).—First, T. Suddick, Tong Street. Second, J. A. Briggs, Rawden.

BRAHMA FOOTRA.—First, J. Walshaw. Second, S. Halliday, Heckmondwike.

ANY OTHER DISTINCT BREED.—First, S. Halliday. Second, J. Holt, Heckmondwike.

GAME HEN (Any colour).—First, J. Vickerman, Chickensley. Second, J. A. Briggs. Highly Commended, H. C. Mason.

JUDGES.—Mr. J. W. Thompson, Southwram, and Mr. J. Crossland, Wakefield.

NEWPORT POULTRY SHOW.

I WAS sorry to see the poultry exhibited in baskets, many of which were not adapted to the inmates. Moreover, it is well known that baskets injure the tails of cocks very often. Can it be any injury of this kind that has made former exhibitors, as Vicountess Holmesdale and Mr. J. K. Fowler, unrepresented at the late show? Some wooden pens would be much better. Many of the baskets which I saw had nothing to prevent the cocks seeing each other, and I noticed two Polish exchanging civilities not calculated to improve their future chances of success in exhibition-rooms.—Y. B. A. Z.

THE DARLINGTON EXHIBITION.

My attention has been called to an error in the report of our late show which I shall be obliged to you if you will correct—viz., you state by a foot note that Mr. Wilson's cup Game cock was disqualified on account of having a tail feather spliced. This was not so. It was the Game cockerel exhibited by Mr. Charlton that was disqualified. You also state that Mr. Fletcher, of Manchester, won the silver cup for the most prizes. This is also an error. The cup was won by Mr. Beldon, of Bingley, who scored one more point than Mr. Fletcher. I shall be obliged by your correcting this also.—J. HOBGSON, *Hon. Sec.*

[We are very sorry that any mis-statement occurred, but our information came originally, we believe, from the Committee. We did not state that Mr. Fletcher had won, but that the award to him was disputed by Mr. Beldon, and was not decided—that is, when our report was written. We have heard from

Mr. Charlton also, who says, "At the Darlington Show I received the first prize for Game cockerel; and in the report in the Journal you have it that the first-prize cock belonging to Mr. Wilson was disqualified for having a sickle feather spliced in his tail. Now I am, as you may imagine, excessively annoyed to say that it is a mistake, and that it was my cockerel that was disqualified. I have been for some time suffering from a severe attack of bronchitis, and was utterly unable to attend to my fowls, and consequently they had to be seen to by the parties who breed and walk my birds. A month before, I saw the cockerel, and he was then all right, and I had not the slightest knowledge of the fraud—in fact, I was as ignorant of it as you could be. You can understand, then, my great annoyance at this unfortunate business."—Eds.]

A GOOD RESOLUTION FOR THE NEW YEAR.

RESOLVED BY AN AWAKENED COMMITTEE.—That after the first day of January, 1866, those magnificent specimens of the poultry yard denominated Turkeys, which at certain of our shows have, from some error on our part, not from any offence on theirs, been subjected to the pains and penalties of imprisonment, shall henceforth be provided with such accommodation as shall not only insure them liberty of person, but shall enable them to display those charms which have so long been hidden from public view.

"B. & W.'s" APIARY—HONEY HARVEST OF 1865.

As your correspondents are beginning to send you in the results of the year in respect to their honey harvest, &c., I am induced to forward to you my usual winter report. I may observe in general that it has not been more than an average year with me, perhaps somewhat below the average, but this is in part owing to the strong tendency to swarm which prevailed more or less during the whole season. However, I take it that this tendency to swarm is in itself indicative of the average character of the honey season, for when honey abounds and the bees are busy collecting it swarming is usually at a discount. All perceptible increase to the store of honey ceased in the first week in July, which is the earliest period I ever remember my bees to have ceased their labours. Ordinarily they add to their stores in more or less considerable quantities till about the second week in August. However, they resumed work at the end of September, and filled up their empty cells, even sealing up a good many. The honey collected thus late was very dark, and had a peculiar flavour which I never remember to have tasted before as collected from flowers. A good deal was collected from the ivy, and this may have helped to produce the flavour I speak of, but it certainly did not preponderate.

Altogether I have obtained 196½ lbs. of honey, of which I have sold £8 worth. This was the produce of twelve hives, four of them being swarms, and six of the remainder having given swarms, several even twice. The largest quantity obtained from any one hive was 32 lbs.

At the beginning of the year my hives stood thus, as compared with the status of my apiary June 14, 1864 (see JOURNAL OF HORTICULTURE of that date):—

BEE-HOUSE.		
A. Hybrid Italian queen. Born 1861. Rich and strong.	B. English stock. Queen of 1864. Very strong and rich.	C. Pure Italian queen. Born 1862. Very strong, and rich in honey.
D. Pure Italian queen. Bred out of C in 1864. Strong and rich.	E. Pure Italian queen. Bred out of C in 1864. Strong and rich.	F. English queen. Degenerated stock. In 1864 had a pure Italian queen; now has all black.
UNDER COVER.		
G. Pure Italian queen. Bred out of C in 1863. Strong and pretty rich.		
GARDEN.		
H. English queen, 1863. Strong and rich.	I. Pure Italian queen. Bred out of C in 1864. Tasmanian hive. Rich and strong.	

The condition of F puzzled me, because at the close of 1864 there were many beautifully-marked Italians, whereas I could not see a single one in the hive this spring. This led me to fear (otherwise there is no truth in the doctrine of partheno-

genesis as pertaining to bees), that my so-called "pure Italian" queen of c was really a hybrid. Other circumstances have convinced me of this, and Mr. Woodbury was of the same opinion when he paid me a visit in August last; but of this more presently, and yet I am not aware that I ever saw any Black English bees in c since it became Ligurianised three years ago; whilst the various young queens which I have raised during the last two seasons have produced a mixed race, in which the golden zones have largely displayed themselves. It is certain, however, that in no single instance has the doctrine of parthenogenesis demonstrated its truth in my apiary, although there were clouds of drones all this summer, bred by at least five (supposed) pure Italian queens, some of them, too, very distinctly marked, making the welkin ring with their noisy trumpeting. I confess to having been very much disappointed at the result of my painstaking labours in weeding out my English blood, which bids fair to prove the stoutest in the contest, and to remain master of the field. In justice to Mr. Woodbury I am bound to say that he has kindly supplied me with another queen, which I sincerely hope may turn out all that he and I could wish.—B. & W.

(To be continued.)

FEEDING RESCUED BEES.

I HAVE bought, in order to save them from the brimstone-pit, a small lot of bees, which only weighs 10 lbs. Last week I gave them a quart of syrup (2 lbs. of sugar in a pint and half of water) in a bottle through the top of the hive, and they have not taken it half down yet.—A. B. B. K.

[Your syrup appears to have scarcely a sufficient proportion of sugar. We use 3 lbs. of sugar to 2 lbs. water by weight. We do not know how you can accelerate matters so late in the season. If the contents of the bottle remain, as they should do, perfectly suspended, and do not drip into the hive, it need not be removed during the winter.]

BEE DYSENTERY.

As your correspondent "A. W." desires the opinions of apianians regarding dysentery in bees, I beg to submit the following as the result of my own experience. Bees in fine weather have little or no disease, foul brood excepted; it must, therefore, be in cold damp weather that we expect such. It is well known that they can raise or lower the temperature of their hives according to circumstances—in fact, that they are a kind of living fire which requires fuel in the shape of honey to keep it up. We will imagine the case of a hive not very strong in numbers: the bees are then obliged to feed more frequently than in one which is strong, for the purpose of keeping up that degree of heat which is essential to their health, and, consequently, when they have filled themselves with honey there is more perspiration, and there not being sufficient heat in them to send the steam off, it falls back and is condensed on and absorbed by them, disease and death being the result. We only look for this disease in cold weather, and in hives which are damp, as dry cold does not injure bees. How, then, can their safety be cared for? as even if there were a medicine for their cure, it could not be administered in such cases since it would only hasten the catastrophe. We must, then, keep as near to nature as possible by applying heat to restore them; and this requires time, because they must be let alone until the weather be such as to admit of their flying abroad. In such cases I choose the first fine day that I can, have some thick boards ready to place below the hives, having had them previously well heated, in fact as warm they can be without burning. When these are put under the hives they raise the temperature, setting the bees in motion, and when these come to the warm board it strengthens them greatly. They are then able to fly out and empty themselves. It is well to do this with all the hives, as the heat tends to dry up any moisture that may be in them.

I add the following for the benefit of "M. S." in regard to queens mating with drones. So late as the 2nd of September, (when I considered that all the black drones were slaughtered, at least they were so in our neighbourhood, and two weeks before that they had made a wholesale slaughter at the moors, and therefore thought there would be none but Ligurian ones living, which two hives had preserved), whilst watching a hive

* I also last year presented my esteemed friend with an Italian queen of unquestionable purity, but she, unfortunately, came to grief on her arrival.—A DEVONSHIRE BEE-KEEPER.

I saw the queen come out and fly for fifteen minutes before the hive; she then went in, but immediately came out again and joined a drone. I watched them till they came down to the roof of the house, but in a minute she returned again, when she again took flight, and this time she must have gone a long way off to choose for herself a husband, as she is now the breeder of hybrids, proving she had been wedded to a black.—A LANARKSHIRE BEE-KEEPER.

POLLEN-GATHERING ON CHRISTMAS-DAY.—Pollen was collected by my bees on the shortest day; but what is even more remarkable, on Christmas-day, which was both mild and sunny, quite a stream of busy and successful little foragers poured in and out of the stock referred to in page 536, filling the air with a delightful melody which, however unusual at this advanced season, discoursed most excellent music to the ear.—A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

DAUNLINGTON SHOW.—We are informed that the first prize for Pouter cocks was awarded to Mr. H. Boldon, and not to Mr. J. R. Robinson.

EGG-PRODUCING FOWLS (A Farmer).—For your farm, and for the purpose of producing eggs, we recommend you to keep Golden-spangled Hamburgs.

PHEASANTS DYING (A. I. H.).—There does not seem any cause for the death of your Pheasants, beyond roup. Instead of a cabbage give them every day several turfs of growing grass, cut with plenty of earth to them. Feed on bread steeped in strong ale, and put plenty of camphor in their water. They will eat the fresh earth, and we believe the course that we have advised will prove a cure. Pheasants at five years old are old birds, and we should advise you next year to save some young ones.

COMMENCING POULTRY KEEPING (B. B.).—You have first to consider your locality and its poultry requirements, next whether you intend to breed for a local or for the London market, whether there will be the readiest sale for eggs or fowls for table. With the appliances you possess you may fairly look for a good profit. For hardy fowls, good layers, sitters, and mothers, we should advise Cochins or Brahmas; for choice table poultry, Dorkings. If there is a good demand for choice eggs, especially in winter, at large prices, Spanish pullets will be required. Such premises as you describe will afford facilities for keeping several breeds; Spanish should be one of them. We believe you should give the Dorkings the chief run; Cochins, Brahmas, and Spanish will do in confinement in any of the out-houses you mention; a run could be afforded for them by enclosing an outer space with wire netting, because, although certain breeds will do well in confinement, they do better with a larger amount of liberty. Common Pigeons will suit best as general breeders, they are hardier and more prolific than fancy ones. There is no occasion for more than a very small outlay to turn any out-house into a perfect poultry place, having perches within 2 feet of the ground, and a dry gravel floor. There are now plenty of good books giving full instructions, and for your stock apply to Bailey, of Mount Street.

FOWLS SUFFERING FROM CHAMP (Subscriber).—The sudden change of weather from extreme drought to constant damp and heavy rains may account for much of the cramp you complain of. It is, however, more often caused by improper flooring for their roosting-places, such as stone, brick, or boarding. If you have either of these remove it; if you cannot do that, cover it some inches deep with dry gravel. If you have no gravel, get that which is most like it. Road grit is an excellent substitute. Onions are very good for Turkeys. Stimulants, such as strong beer, a mixture of bean, pea, and barley meal slaked with beer is good food. The chickens will rally by having bread steeped in it. The present weather will necessitate generous feeding.

BREEDING SEBRIGHT BANTAMS (Sebright).—Many, indeed most, breeders mix their Gold and Silver Bantams. Still, if you wish for silver birds, you are more likely to have them from Silver than Golden birds. Unfortunately all the Silver now have a golden tinge.

TURKEYS BREEDING (H. A. P.).—Turkeys will breed for many years, but as they get old they are less prolific. We should not keep them after five or six years. Both sexes should not be old alike, but where one is old care should be taken to mate with younger.

DORKINGS' COMBS (Scotchman).—If every other point were equal, and the large comb was in every way perfect, we should certainly prefer it to the small one. Small combs are not characteristics of the Dorking breed. If the large comb lopped or fell over, it would be a disadvantage, and we should prefer the smaller one.

COCHIN-CHINA COCK'S COMB (B. H. H., Jun.).—Uneven serratures in the comb do not disqualify, though they should be considered if the competition were close. We take for granted that you do not mean "sprigs" on the side of the comb, which would be a fatal objection, probably.

FOOD FOR GOLDFINCHES (N. N. S.).—You had best feed your Goldfinch on good, sound, and bright canary seed, give clean water, and keep the cage sandal. It may have chickweed, groundsel, and the heads of thistles, dandelion, and plantain when in season. A little maw seed is good, but hemp and rape seed are to be avoided.—B. P. B.

POPPY SEED FOR BIRDS (S. J.).—The seeds of *Papaver somniferum* are very small bluish seeds, sold for birds under the name of "maw seed." They are not injurious to small birds. The seeds do not contain opium, but they contain a very fine oil, and are much better for cage birds than either rape or hemp seed.—B. P. B.

POULTRY MARKET.—JANUARY 1.

SENDERS seem to have exhausted their stocks and their energies, and the supply of most articles depends on parcels that have been buried for days under hecatombs of Geese and Turkeys, and now come to light. Most Christmas markets are alike, and while there is almost always a good demand for the best of all sorts, much that is inferior is difficult to sell at any price.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 41.9; and its night tenperature 30.5. The greatest heat was 56° on the 14th, 1849; and the lowest cold 4° below zero, on the 14th, 1838. The greatest fall of rain was 0.80 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

BUSH PEAR TREES ON QUINCE STOCKS IN YORKSHIRE.

THE following are a few notes on bush Pears on the quince stock as grown amongst the hills of Yorkshire, where the climate is not warm enough to admit of the

successful cultivation of Wheat:—

Doyenné d'Été makes a very short but robust growth on the quince stock, and bears an abundance of fruit, which ripens about the 1st of August. The fruit should be gathered before it begins to turn yellow. It will then be melting, juicy, and sweet. It soon becomes mealy if kept more than a day or two.

Beurré Giffard forms a small but compact bush on the quince. The growth is quite satisfactory. The shoots require to be shortened to 4 or 5 inches in length about the beginning of July, as the tree forms fruit-spurs sparingly. The fruit ripens well, and is melting and juicy, with a flavour resembling the Jargonelle.

The Jargonelle forms a dwarf spreading bush on the quince. It requires the same treatment as Beurre-Giffard, and bears freely and regularly. This tree bore forty-four good-sized Pears last autumn.

Beurre Goubault makes a most beautiful bush, like a forest tree in miniature. Bears abundantly and regularly. The fruit ripens well, is juicy, melting, with a pleasing aroma. It is ready for use about the first week in October. This variety bore seventy fruit in 1864, and ninety in 1865.

Fondante d'Automne forms a beautiful vase-shaped bush, bears freely, and the fruit ripens well, and is melting and sweet, with a most agreeable aromatic juice. It is ready for the table about the middle of October. This bush produced forty-eight fine fruit in 1865.

Rivers's Summer Beurre d'Arenberg grows freely on the quince, is healthy, and shows no signs of canker. It will be a free bearer, I think, because the tree is already studded with fruit-spurs. A good hardy Pear is much wanted to succeed Beurré d'Amant's, and to be ripe about the middle of September, between that Pear and Louise Bonne or Fondante d'Automne. As Mr. Rivers states that the Summer Beurre d'Arenberg is ready for the table early in September, and is of excellent quality, it will, no doubt, form a valuable addition to our early autumn fruits.

Beurre Superfin makes a handsome spreading bush, grows vigorously, and ripens its wood well; but hitherto the blossoms have always been small and weak; even this year it has only managed to set one fruit, while another tree on the quince, trained against a south wall, puts forth healthy fruit-spurs, and bears freely. The flesh is very

fine-grained, very juicy and melting, with a most refreshing acidulous flavour. My gardener has used his utmost skill to make this tree bear fruit as a bush, but hitherto without success. I can only conclude that it requires a wall in cool climates. There is one peculiarity I ought to mention—the fruit when ready for gathering will not easily part from the spur, but some slight force must be used in order to detach it.

Alexandre Bivort forms a handsome spreading bush, grows freely, and puts forth a proper amount of fruit-spurs, but it is (like Beurré Superfin) too tender to succeed as a bush, and, therefore, requires a wall in cool climates; whether it is deserving of such a situation I am at present unable to state.

Comte de Lamy assumes the shape of an upright cup, makes a stout robust growth, and produces a moderate crop of medium-sized fruit, which ripens well in October. The flesh is melting, juicy, and most excellent. The tree is hardy.

Doyenne Boussoch grows into a fine spreading bush, and bears freely very fine large fruit, which ripens well. Two Pears of this variety weighed 18½ ozs. The flesh is crisp and juicy, with the flavour of an Apple, and very refreshing. This fruit is ripe towards the end of October, and is quite distinct from any other Pear I have ever tasted.

Beurre Hardy forms a very handsome spreading bush, remarkable for its vigorous growth and the beauty of its abundant rich green foliage. It must be able to flourish in the most unfavourable soils. This bush has been forked out of the ground every year for the last four years, and it seems rather to like the operation than otherwise. It produces large pyramidal-shaped fruits; flesh melting, and very juicy, with a slight yet agreeable perfume. Ripe early in November.

Comte de Flandre assumes the form of a Cypress, and is decidedly the most beautiful tree in the collection. It puts forth in spring fine large trusses of bloom, which remain a long time in flower; every bloom passes into a fruit, which has no idea of tumbling off, so the scissors must be freely used. One fruit weighed rather more than three-quarters of a pound, and all the rest were fine, large, pyramidal-shaped Pears. The first fruit was ripe on the 10th of December, the second on the 20th, and the remainder of the crop is still in the fruit-room; so this variety ripens slowly, and is not inclined to decay. It comes into season in December and January. Flesh fine-grained, without a core, melting, very juicy, sweet, with an agreeable aroma. A jury of three persons voted it to be superior to Glou Morceau grown against a south brick wall. This is likely to become a valuable winter Pear, and to deserve a wall in unfavourable situations.

Baronne de Mello grows freely, and produces blossoms in abundance, which never set. It is decidedly too tender to succeed as a bush in a cool climate. It requires a wall.

Doyenné Defais forms a healthy upright tree, which will bear abundantly against a south wall, but as a bush its flowers are too weak and tender to be fruitful. This Pear has borne one fruit this autumn, which ripened perfectly.

and which, in shape, size, and flavour, resembled Winter Nells. Flesh fine-grained, melting, rich, but it differs from the Nells in having a refreshing acidulous juice very agreeable to the palate. It is a first-rate Pear, ripe in November.

The Seckle on the pear stock forms a healthy vigorous bush, bears freely, and opens its sweet, perfumed fruit.

With my present experience of bush Pears, I should recommend for cultivation the following six varieties: *Jagouelle*, *Bearé Giffard*, *Fondante d'Autonne*, *Louise Bonne*, *Bearé d'Amandis*, and *Comte de Lamy*; and if six more were desired I would add *Bearé Giffard*, *Summer Bearé d'Arenberg*, *Stuffell Thorn*, *Autumn Bergamot* (double-worked), *Seckle*, and the *Hessle*. This last variety is sometimes incorrectly spelt *Hessel* and *Hazel*. It was introduced from abroad by an ancestor of Mr. Pease, of Hessewood; hence its name. C. I. M.

ROSES FOR THE NORTHERN DISTRICTS.

At page 511 of the volume of the Journal just concluded, a correspondent (J. Hunter) is referred to the Rev. Mr. Radclyffe's list in No. 191, for Roses suitable to the north of England. It is certainly a good one, but it contains varieties that I have not yet found to open quite so freely here as I would wish. I will, therefore, pointing that your correspondent is a beginner, and not about to commence on a large scale, point out those which I think most likely to suit him. I have not grown the whole of the summer Roses enumerated, but the following I can vouch for, and I think they may almost be considered the cream of the lot: *Vivian*, *Madame Zouffrou*, *Charles Lawson*, *Coupe d'Hôtel*, *Chénébolé*, *Bacchus*, *Paul Ricaut*, *Kean*, *Moss Lancet*, and *Baronne de Wagram*. To these may be added *Comtesse de Murinais*, not a fine Rose, but it blooms freely, and is very hardy. I have no doubt that many of the others would succeed well with Mr. J. Hunter, but those I have named are good, and may be relied on.

Now for the autumnal kinds, which on account of their perpetual-blooming qualities are more highly prized than the others.

Whites, or nearly so.—*Ardalis*, rather shy in opening sometimes; but good autumnal whites are too rare for it to be omitted; *Souvenir de la Malmaison*, *Mrs. Bosanquet*, and *Madame Videt*. I would like to add *Madame Rivers*, and *Caroline de Sansal*, but my plants of these varieties were put in late, and consequently have not yet had a fair chance. I cannot, therefore, speak positively in regard to them, but they are beautiful Roses, and certainly well worth a trial.

Rose Colours and Shades of Pink to Light Carmine.—*Anna Alexieff*, *Anna de Diesbach*, *Comtesse de Chabrilant*, *William Griffiths*, *Louise Polromny*, *Louise Olivier*, *Catherine Guillot*, *Baronne Prevost*, *Cajonel de Rougenout*, *J. M. Hopper*, *Madame Boll*, *Jules Margottin*, *Victor Verdier*, *Baron Gonella*, and *Paxton*.

Of the above, *Baronne Prevost* and *Cajonel de Rougenout* are very much alike. Should both not be required choose the former, its habit is much more robust, and, therefore, more likely to succeed; the latter is, perhaps, the finer flower of the two, but there is really very little difference between them. There is also some resemblance between *Comtesse de Chabrilant* and *William Griffiths*, but the *Comtesse* is decidedly the better. *Paxton*, on the *Manetti* stock, grows vigorously, and is well adapted for a pillar.

There is another Rose which ought, perhaps, to have been included with the above, but its colour scarcely comes within the range; I must, therefore, give it a place by itself, and a note of praise also, for it fully deserves it. I allude to *King's Acre*, a double bright vermillion. This is really a superb Rose; its fine habit, hard constitution, and splendid flowers are sure to make it a favourite. I shall be much mistaken if it do not hold its place as a first-class flower long after many of our more highly-coloured varieties have disappeared. Our old friend *Jules Margottin* has met with a powerful rival at last, one for whom he must, in my opinion, ultimately make way. I feel convinced that, both in the show-room and rosery, this fine Rose must long occupy a prominent position. The one or two blooms I had of it were very fine. As my remarks are chiefly intended for amateurs who have had little experience in the cultivation of the Rose, I may mention that on receiving a plant of this variety about the end of last January, I had occasion to shorten one of the branches at the time of planting. The part cut off I was about to throw away, when it occurred

to me that something might be done with it. I consequently looked up a *Manetti* stock, and made a graft of it, which I potted and placed in my sitting-room window under a glass shade, for I had no bottom heat at the time, and I have now for the little trouble I took, two nice plants instead of one. I merely mention this to show that there are more ways than one of doing a thing.

I must now notice some of the most eligible of the high-coloured varieties. There is a great deal of sameness in many of them; but most of the following are distinct and good, and will not fail with proper treatment to give every satisfaction.

Crimson, Rosy Crimson, and Scarlet.—*Charles Lefebvre*, *Gloire de Saintenay*, *Sémateur Vaise*, *François Lacharme*, *Prince Léon*, *Baronne Hallez*, *Beauty of Waltham*, *Madame Charles Craplet*, *Géant des Batailles*, *Général Jacqueminot*, *Maurice Bernardin*, *Duc de Rohan*, *General Washington*. The last three do not at all times open quite so well as I would like, but they are grand Roses, and should have a place in every collection.

The following are good, but not equal to the above—viz., *Lord Raglan*, *Maréchal Vaillant*, *Eugène Appert*, *Duchess of Norfolk*, *Turenne*, *Buffon*, *Souvenir de Leveson Gower*, *Triomphe de l'Exposition*, *Triomphe d'Alençon*, *Madame Louise Carique*.

Of the first selection, *Beauty of Waltham* and *Madame Craplet* are very much alike, so much so that the difference between them at times is barely perceptible. I am, however, of opinion, that they are distinct Roses. *Madame*, if anything, is the larger and bolder flower of the two, but the *Beauty* is smoother in the petal, and brighter in colour, and, I think, more lasting, at least such is my experience of them here.

Darker Varieties.—A great many have been introduced of late years, and they are certainly very beautiful, but I do not think, generally speaking, that they succeed so well in the north as the lighter colours. Of all the varieties I have tried, none have done so well with me as *Empereur de Maroc*. Its flowers if anything are rather small, and in other respects not quite perfect, but it is one of those gems without which a collection would not be complete. It grows very freely, and its beautiful dark maroon flowers are very fragrant. If others are wished for, the following may be tried, but they have not yet given me entire satisfaction: *Prince Camille de Rohan*, *Alfred de Rougenout*, *Duc de Cazes*, *Jean Bart*, *François Arago*, *Cardinal Patrizzi*, and *Victor Emmanuel*.

With regard to *Tea-scented Varieties*, I would recommend your correspondent to have very little to do with them, at all events for out-door purposes. Our atmosphere is too cold and humid for their successful cultivation in the open air. *Gloire de Dijon* is an exception, it is by far the finest of the lot, and cannot be too largely cultivated. This variety and *Empereur de Maroc*, budded on a nice healthy stem about 2 or 3 feet high, make a fine union standard. The contrast is striking and beautiful.

Of *Yellow Varieties*, *Celine Forestier* and *Triomphe de Rennes* are the best. The Austrian *Briars*, *Harrisonii* and *Persian Yellow*, may also be tried. *Bourbon Queen*, of a buff salmon colour, is a free bloomer, but of no great merit in other respects.

I may possibly have omitted many good and suitable Roses in the above lists, but out of about 140 varieties I have found those named to succeed best in this locality. Last season, however, was very trying, and should the next be more favourable I may be agreeably disappointed with some of the others. My plants suffered severely from mildew, some varieties more than others, but all were more or less affected by it, with the exception of *Triomphe de Rennes*, which escaped altogether.

In conclusion, I would recommend your correspondent, and others in similar circumstances, to be very careful in selecting new varieties. It is better to begin with a few established favourites than to make selections at random from the descriptive catalogues of nurserymen, which, although generally very truthful, cannot safely be taken as a guide under all circumstances. Soil and situation are everything with the Rose. The catalogues themselves show this, for we frequently find varieties in the first class of one that are only allowed a place in the third or fourth classes of another. This is simply owing to what I have stated, for in no other way can so much difference of opinion be accounted for. It, therefore, shows the necessity of ascertaining beforehand whether any particular variety that may be desired is likely to suit the locality in which it is intended to be grown; in order to know this we can never do better than consult the nurserymen from whom we obtain the plants.—LECH NESS.

MY ORCHARD-HOUSE.

I took my first idea of the construction of an orchard-house from Mr. Rivers, and in erecting my houses I followed the directions contained in his excellent work on the "Orchard-House." I went economically to work, had my rafters and plates all cut and planed by machinery, and hired a handy carpenter at 4s. a-day, who, singly, built, glazed, painted, and, indeed, planted my house. I repeat, that in erecting the structure I followed the directions of Mr. Rivers, but in selecting, planting, and pruning my trees, I as implicitly followed the plan recommended by the Rev. T. C. Bréchant. In training my trees I indulged a fancy of my own.

One fine day, happening to be in Longmans' shop in Paternoster Row, I stumbled upon my friend Mr. Bréchant's treatise on "Diagonal Cordons," which at once rivetted my attention, and determined me to erect an orchard-house. Accordingly, I tried my hand on a small span-roofed one, about 40 feet by 10, and 12 feet high, but was very unfortunate, as in the second year (two years ago), I overloosed my house with the smoke of gas tar to kill the aphides, and this stripped my trees of all their leaves, and gave them a check from which they have only this last season recovered. Nothing daunted, I set to work, and my man built me another span-roofed house, length 162 feet, breadth 23 feet, height 15 feet to the apex, and 7 feet in height at the sides. There are five wooden platform walks the whole length of the house, the centre walk 5 feet wide, and the other two walks on each side 2 feet wide. These walks are made of deal boards, planed, and have an aperture of about an inch, so as to allow the "skyey influences" to have their effect on the subjacent soil.

I planted my trees 3 feet apart; and according to my friend's direction, I commenced to train them at an angle of from 65° to 70°, until the period arrived to lower the branches to their proper berths—viz., to the angle of 45°. Previous to planting my trees I had strung my house throughout with thin galvanised iron wire, No. 14, a foot apart, at an angle of 45°. These wires, commencing about a foot from the ground, extended first to within a foot of the glass, in a line with the platform walk, then, at the same angle, following the slant of the roof up to within a foot of the apex, and so continued down the other side at the same angle, so that my trees on one side have an inclination to the north, and on the other to the south, which has a beautiful effect. Of course, one tree fills three wires, the branches being a foot apart in accordance with my friend's instructions. I have another row of trees between the two platforms on each side, all trained in the same way. The outer platform on each side is close to the glass, and to the ventilating-doors, which are 14 inches deep, extend the whole length of the house, and are let down outside on hinges so as to just clear the ground. These doors, as well as three larger ventilators which I thought necessary to place in the roof, I have always kept wide open, night and day, after the third week in May. I have fruit trees of all kinds, but chiefly Peaches, Nectarines, and Apricots, all pinched *à la* Rivers, and pruned *à la* Bréchant; indeed, were the trees not so pinched and pruned they would soon become a mass of confusion; whereas, now, the branches are all fringed round with short shoots reduced to obedience. No gourmand shoot can live under such severe discipline. I had a most abundant crop last year, too many indeed, and I am now busy pruning. "I cut boldly and fear not," as my friend enjoins, and I find the observation of Mr. Rivers quite correct, that "Cut as you will you are sure of plenty of fruit;" but I recommend all amateurs to follow the rules prescribed for wood and fruit. In addition to the diagonal cordons of the centre, I have one hundred pyramids—viz., fifty on each side, alternately in pots and in the borders, but I mean to remove them if they at all mar the progress of the diagonal cordons, which are to be the permanent trees.

I fear that I am trespassing on your space, but I cannot refrain from exulting in the idea of the magnificent spectacle which the centre, or crinoline walk as I term it, will present with the groined arch of beautiful fruit trees overhead; for already in this, the third year, some of the trees are advancing towards their destination, the apex. In describing my house, I omitted to state that I have at the north end of it a lean-to house 80 feet long, and 13 feet broad, and of the same height as the span-roofed house, which runs into it, and, in fact, the two form one building. The trees on the back are on diagonal wires 8 inches from the boards, and, of course, fringed all round like a sweep's fine-brush. Most of these trees have reached

the top of the house. I water my trees with two longitudinal gutters, one on each side, made of zinc, and perforated at the bottom with holes a foot apart, just large enough to admit of being closed with galvanised round clout nails, so that I can, at pleasure, alternate the supply to my trees, as I have an abundance of water. This gutter I make fast to the rails which extend the whole length of the house, and to which the diagonal wires are attached. I have about 450 trees in my large house.

I may add, that I have on my ground, constructed a Pear and Plum trellis about 450 feet long and 15 high, on which I am training my trees after M. Du Breuil's plan, each tree 14 inches apart, and pruned *à la* Bréchant, and trained at an angle of 45°, but I have dispensed with diagonal wires, and use instead horizontal wires 18 inches apart, to which I attach osier rods, which are removable when you want to lower the branches to the proper angle. Indeed, were I to start *de novo*, I would adopt that plan in the orchard-house, and dispense with diagonal wires altogether, as there is some trouble in keeping them tight.—RICHARD CLAY, *Rose Bank*.

P.S.—Since writing the above, I notice that in a late Number Mr. Bréchant makes mention of the method of training adopted in my orchard-house.

CYCLAMENS.

In reply to Mr. Abbey's inquiries, I regret to say that I am not able to name the varieties of Cyclamens which I found growing in Sicily, Syria, &c., for I unfortunately lost my dried specimens of them. My impression is that it was *C. nuphoides* which I found growing in such profusion in Sicily during the latter part of March. I happen to know that it was the earliest-flowering variety, because a botanical friend, who travelled by the same road a fortnight before me, could not find any then in flower. This last spring was very late in Italy, heavy snow fell low down the sides of Etna late in March. As regards the soil in which they grow, I invariably found them growing on as hard a bed as possible, never on a soft, loose soil, but as invariably covered with a loose, open, friable soil, often composed of decayed leaves mixed in the soil, and sometimes of soil alone, as loose and open as the mould of an ant's hill. Of one fact I am certain—of the three or four varieties which I found all were more or less deeply covered with loose, open soil; and the stalks of the leaves and stems of the flowers appeared so much to enjoy, and to derive so much benefit from their contact with the humid soil, that I am an advocate for providing all varieties, whether in pots, pits, or open beds, with their natural requirement.

I am quite sure that Mr. Abbey does not mean to be satirical in saying that "imitating nature sounds well. It is little carried out in practice." That is the very point to which I wished to draw the attention of your readers—viz., that if we diverge from the path of nature by endeavouring to grow to perfection certain plants without providing certain accessories which we find them enjoying in their native localities, we are retarding rather than promoting the enjoyment of Nature's best gifts, in fact, I may say we are actually placing unnecessary difficulties in our own way; for if Mr. Abbey could see the thick succulent stems of the leaves and flowers when bared from the soil, he would not hesitate for a moment in deciding that a covering of loose soil or vegetable compost is not only advantageous, but actually requisite, for the well-being of all members of the Cyclamen family.

I have long been of opinion that the principal difficulties which we have to encounter in the cultivation of plants is our ignorance of their actual natural condition and requirements, and a reference to some of your older volumes will show that I have endeavoured to point out this requirement in some of our British plants, now, alas! becoming so rare as to be deemed almost extinct. As a case in point I would mention a circumstance connected with a plant not unlike the Cyclamen in leaf. Some years ago I sent you a specimen of *Asarum virginicum*, of which I had managed to raise a good length for an edging plant, on account of its rich glossy leaves. Your excellent coadjutor Mr. Beaton wrote immediately—"I have not seen that plant for twenty years, pray tell me how you managed to grow it so well;" and another of your correspondents asked me to exchange with him a plant of it, for which he sent me another variety of *Asarum*. When it arrived it appeared to be different from my own, it had a thin, pale green leaf, different from the thick, dark, shining, green foliage of my own plants; but after it

had lived a short time in the same position as my own it became one of the same variety, and could not be distinguished from them in leaf or any other particular. To Mr. Beaton I was able to reply that I had succeeded simply by noticing the plant's natural requirements, which were that it preferred shade to sunshine, and would only grow to perfection where it had plenty of shade from the sun, when it rewarded me by flowering and fruiting abundantly, besides making a most beautiful edging in a position where few other plants would grow at all. Instead of longer availing myself of my *nom d. plume* I venture to subscribe my name.—W. WASKLYN.

VINE CULTURE.

SINCE your correspondent Mr. Wills invites discussion through your pages on the above subject, and as we do not happen to think alike on some points, I venture to solicit a portion of your space for the following remarks. Not having in my possession at present those Numbers which I infer contain the first part of Mr. Wills's article on the cultivation of the Vine, my remarks refer only to what he has stated in No. 242, page 398.

Vine culture is a subject that has been so often and so thoroughly sited of late years, that it would be difficult indeed to broach any new or profitable idea upon it—a fact which your correspondent seems to have been unable to overcome; nor is it with any pretensions to being able to do so myself that I intrude upon your pages, but simply with a desire to modify to some extent the impression which I think Mr. Wills's remarks are likely to make. With regard to what he says about pruning, covering the borders, and such like, I have nothing to say. His remarks upon these matters are unobjectionable; only I think that he entertains unnecessary fears about using the seissors. In inexperienced hands they are, perhaps, not to be recommended, but we know that they have been, and I have seen them, used with perfect safety and success by those who have claims to be considered authorities on the subject of Grape-growing; but this is a point of comparatively little importance. Concerning the necessity of painting Vines, however, as a preventive of red spider, I do not entirely concur with Mr. Wills. I know by experience that in some places, and upon some soils, red spider is one of the greatest scourges that the Grape-grower has to contend with, and he who finds it necessary only to scrape off a little of the loose bark in order to rid himself of this pest has good reason to be thankful; but it does not follow that his experience applies in every case. I certainly never heard of cowdung being recommended for the above purpose, nor am I aware of its possessing any particular virtue as an antidote in this respect. I have seen soot and sulphur, and also clay employed in the form of paint, and I used to think the necessity of applying these, or anything else that was likely to arrest the ravages of the destroyer, pretty evident; latterly, however, I have preferred using soft soap and water, scrubbing the rods well with a hard spoke-brush. I think this is the cleanest, cheapest, and most effectual plan I have seen tried, and if carried out before the buds begin to swell there is no danger of injuring them.

Your correspondent's speaking of lowering the points of the Vines before starting, in order to induce these to break regularly, suggests something to my mind which appears to me to account as well as anything else for the irregular breaking of Vines in many cases. I am aware that the rush of sap to the top of the shoot is generally considered to be the cause of this, and I am not prepared to deny that to some extent it may be so; but I am convinced that breaking irregularly is more owing to the different parts of the Vine being exposed to different temperatures, and in this opinion I am sure that the experience of others will bear me out. I have invariably noticed that the best bunches of Grapes and the strongest shoots are always at the bottom of the house, where the Vines are in proximity to the pipes, or at the top, to which the heat ascends and there remains, while the weak shoots and small bunches are in the middle. This I have always noticed, more particularly in early vineries, where, from necessity, little air could be admitted, and where the temperature was almost entirely dependant on fire heat. In late vineries irregular breaking is less common, simply because less fire heat being required, and more air being admitted, the temperature of the house is more equal. The inclination of heated air to ascend straight upwards is well known and understood. In a vinery where the pipes run along the

front of the house, the cold air coming in contact with them, and becoming heated, rises straight up to the glass roof, which it follows until it reaches the top of the house, and there it remains, unless the ventilation is sufficient at the time to let it escape, otherwise the heat can only do so by radiation; but the ascending current from the pipes supplies more than what is lost in this respect. The fumigating-pan affords a familiar and practical illustration of what I mean. Under these circumstances a few feet of the Vine rods directly above the pipes, and that portion of them at the top of the house, are subjected to a higher temperature than the middle part; hence the result. A far preferable plan to lowering the points of the rods at the back of the house is to lay these horizontally along the front; but were it not inconvenient for other reasons, it would be a better plan to distribute the heating apparatus more equally over the floor of the house.

In conclusion, allow me to notice one or two other points in Mr. Wills's article. On the subject of temperature, I think he advises undue caution. When starting Vines the temperature has often to be regulated by circumstances, and must be left a good deal to the judgment of the gardener. Much will depend upon the backward or forward state of the Vines, and upon the state of the weather out of doors at the time. When it is necessary to use some amount of fire heat to raise the temperature to the desired point, then a low degree of heat is advisable; but if the weather is mild at the time, and has been so for some time previously, then a temperature of from 50° to 55° is quite safe to start with. I think it an unnecessary degree of caution to advise such a long-continued low temperature as that recommended by Mr. Wills. When once the bunches fairly show themselves, I consider a temperature of 50° too low. A rise from about 55° to 60° at night, according to the weather, and a proportionate rise in the daytime, are necessary, and materially assist the proper development of the bunches.—T. S. W.

ROSES.

I HAVE read what "COUNTRY CURATE" has said, at page 520, with regard to Roses on their own roots succeeding better than on alien stocks. I cannot definitively speak, having had so few Roses on their own roots as compared with those on the Manetti and briar stocks. Some that did not do well on either of the above stocks succeeded well on their own roots, and *vice versa*. When Roses are raised on their own roots they require to be taken great care of for some time. So far as my experience goes, they do not generally bloom so early, abundantly, quickly, or late, as Roses on the Manetti, in my soil. The same remarks also apply to Roses on the briar. However, much depends on the sorts, and also on the soil. There is nothing that I have seen that will touch the Manetti Roses in poor, dry, and shallow land, highly manured, and kept well watered.

I do not agree with the saying of the late Mr. Beaton that Manetti is only of use to strike Roses on their own roots; but, I do say, that it is the best and surest way to raise Roses on their own roots. As I am about to leave Rushton in April, to reside at Child Okeford in this county, I removed several hundreds of my Manetti Roses to a spare garden here, where they will remain till I am able to remove them to my new residence, rented of Lord Rivers, one of my oldest friends. I found that some of them, although planted eleven years, were still only on their Manetti roots, but the most of them were double-rooted. From such as had been budded too high I cut off the Manetti roots, otherwise I merely shortened the Manetti and other roots. Some sorts, in the same family, will root much more freely than others. The two great rooting times are in the spring, and again in September, after rain. If "COUNTRY CURATE" wishes to get Roses on their own roots from the Manetti, he must plant them 2 or 3 inches over the collar of the bud, and keep them mulched and watered in hot weather. He must also protect the roots during the first winter. There is no doubt that originally Manetti Roses were budded too high, and the radius of the roots was necessarily planted too deep. All trees struggle to make surface roots, and I do not think they will flourish long without them. If my readers have a Manetti Rose budded 9 inches high, the best chance of success will be to bury it sufficiently deep to strike on its own roots. There is no occasion to cut the bark. The Rose will strike in suitable weather (hot, dripping weather) without it. Still it will do no harm to cut a nick over an eye,

and close the earth over it. Probably this may be of great assistance to some sorts that do not root freely. I have found that by earthing up spriggy plants every branch rooted.

For striking cuttings September is the best time, because the earth is hot, and the day and night atmosphere is colder, and the sap is not so soon exhausted as in summer. The best place to strike Roses from cuttings is under a wall facing the north. There they have sufficient heat without being exhausted by the direct rays of the sun. When "COUNTRY CURATE" pots his cuttings he should place them in a shady spot. His failures arose from one of two causes, either from carelessness, or the drying up of the new tender rootlets.

With regard to Roses on the Manetti, whether they are double-rooted or not, I can say that I never saw anything equal to them as a class. They began blooming out of doors in 1864 on the 7th of May, and in 1865 on the 14th of May, and never stopped but one week till they gave up in the winter. As soon as the main wood had bloomed its amazing crop, the new shoots from the base began in a week to bloom; and, by the time these blooms were over, the next series began again on the worked wood, and that wood never ceased flowering; to which might be added the next series of flowers from the base shoots. A briar Rose never can be more than one Rose, but a Rose on the Manetti (by striking, or being on its own roots) may become many. The most favourable place for striking Roses on the Manetti stock is the point of union; but, if the stems are earthed up high enough, and kept sufficiently moist, some sorts more than others, they will strike abundantly, and give compound interest on their own roots besides the Manetti plant. I have reserved about 1200 plants to go with me. They are now all together, and will be a fine sight. I do not think of moving them till next fall.—W. F. RADCLIFFE, *Tarrant Rushton.*

COOL ORCHID CULTURE.

I OBSERVE the following remarks by Mr. Keane respecting the cultivation of Orchids—"A high temperature was supposed necessary for their growth; to prove how erroneous that idea is we would suggest a friendly visit to some of our most successful neighbours." Would your correspondent be kind enough to name a few places where Orchids are cultivated successfully under cool treatment? as I happen to be among the number of those who think a high temperature absolutely essential to the successful management of Orchidaceous plants. I know there are a few exceptions, as some of the *Odontoglossums*, *Lycastes*, and a very few others, that thrive better in an intermediate house, but not a greenhouse. I have visited several places where it has been attempted to grow *Saccolabium*, *Aërides*, *Vandas*, &c., in a cool house, and in every case it has proved a failure. A few months ago I expected to hear of *Vanda tricolor* and *Cattleya labiata* being strongly recommended as bedding-out plants, so enthusiastic were the advocates of the cool system.—B. F., *Manchester.*

[I beg to refer "B. F." to Messrs. Lee, Hammersmith, Mr. Veitch, Chelsea, Messrs. Rollisson, Tooting, Mr. Backer, Wandsworth, and, in short, to every grower of Orchids to prove, by ocular demonstration, that some kinds delight in a low temperature. For example, the treatment required for *Oncidium carthagenense* would kill *O. bifolium*; *Cattleya Forbesii* will thrive where *Cattleya Skinneri* will die; and in like manner *Dendrobium pulchellum* demands an amount of heat and moisture which are unnecessary and indeed injurious to *D. aureum*. To study the climate of the countries and localities from which the species come is the only sure guide. It is no wonder that plants from the same country require very different treatment, as Orchids grow in the tropics at all elevations between the level of the sea and 14,000 feet of altitude, and, therefore, they will require a great diversity of climate. When the many rare and beautiful species were sent home from the high lands of Mexico and Guatemala, Mr. Hartwig informed us, in his letters, that the thermometer was sometimes near the freezing point where many of them grew, and this was confirmed by the quantity of small mosses which were found growing upon some of the branches to which the plants had attached themselves. Many of them were removed into a house which was kept cooler than the Orchideous stove, and they succeeded much better than others of the same kinds which were allowed to remain in a high temperature, where they were over-excited, and grew sickly and languid, forming small pseudo-bulbs every year, until they finally perished. Many

growers have experienced the same results. The house in the Horticultural Society's Garden at Chiswick, where they were grown, had no artificial heat during the greater part of the summer, and in winter it was kept at about 55°. The air, however, was kept more moist than in a common greenhouse.—W. KEANE.]

VISITS TO GARDENS PUBLIC AND PRIVATE.

MESSRS. LOW & SON'S, CLAPTON.

AMONGST the old-established nurseries in and about London, none is better known or more deservedly celebrated than that which for so many years has been known as that of Hugh Low & Son, Clapton; and although the head of the firm not long ago died full of years and honours, yet it is still carried on with the same vigour and energy which have characterised it for so long a period. It was on a miserably wretched day in the month of October, when the rain came down in "bucketsful," that I found myself at the nursery, and was fortunate to have an hour or two's tour of the houses accompanied by Mr. Stuart Low, from whom I learned much that was new to me, and saw much that was novel also.

In some very important respects the Clapton Nursery has *spécialités* of its own. One will not find in it the magnificent specimens of stove and greenhouse plants, and Orchids, that are to be seen at Mr. Veitch's or Mr. Williams's, nor the curious and multitudinous novelties that Mr. Bull grows; but you will see houses full of Orchids in every stage, from the plants just imported to those which are growing finely and flowering; whole ranges full of Heaths, especially those for winter and spring decoration; thousands and tens of thousands of young Conifers grown from seed; house after house filled with *Camellias* of all sizes and kinds; not a great deal of order and neatness, but an air of business that showed that matters were thriving; and that as this house has contributed in no small degree to the taste for horticulture by the extensive importations it has made from all quarters of the globe, so it is in its turn deriving no small degree of benefit from that increased taste.

And now as to the Orchids. It is well known how many beautiful plants of this remarkable tribe have been added to our collections by the enterprise of this firm; and it shows the manner in which it is ready to seize upon any fair opening, that immediately on the cool treatment of Orchids coming into vogue, a collector was dispatched to South America to obtain from the high altitudes of New Grenada and Guatemala the *Odontoglossums* and other Orchids with which those districts abound; and it may give an idea of the extent of the importations to say that in three months were received about 150 cases of Orchids. Were these all to arrive in good condition they would indeed afford a rich harvest; but they have to go through an ordeal by which hundreds of them perish. They are collected on the heights of New Grenada at an altitude of 24,000 feet, where the average temperature is about 42°; but before they reach the steamer they have to come down eight hundred miles to the coast by the Magdalena River, one of the hottest steaming countries in the world. The consequence of this is that they actually melt, all the tissue turning into water, so that when the skin of the pseudo-bulbs is not burst you can squirt the water out of them as out of a syringe; but in some species when even this is the case, and the rhizome is sound, the plant will recover and make fresh bulbs, as, in fact, I saw many of them doing. Amongst the *Odontoglossums* were *gloriosum*, *bluntii*, *radiatum*, and many others, which are most probably entirely new, and thus promise the incentive of novelty and expectancy to those who purchase; for hitherto that numerous and increasing class of horticulturists to whom Orchids are precious—some thinking they can detect something strange and novel, others pretty sure that they have found a gem, and many contented with anything they can pick up. Of *Cattleyas* from New Grenada there was also a great variety, in every degree of colouring, from that of *Mossie* to pure white. Then there were *Dendrobiums* of all kinds—*albo-sanguineum*, very rare, from Moulmein, growing well. Look, too, at this lot of *Lælia anceps*, imported only in June, and now flowering; and *Lælia majalis*, assumed by most to be a difficult plant to grow, but here doing well, and that in a low temperature.

On the subject of low temperatures for Orchids I had a long and interesting chat with Mr. Low, he being decidedly of opinion that a great deal more has been said of it than it warrants; and that many persons, misled by what has been written on the subject, will burn their fingers, or rather, should we not

say, get them frost-bitten? Orchids, it is true, will do at a low temperature; but to suppose that they can be grown as ordinary greenhouse plants can be, is only misleading. They require exclusion from air, and not so dry a temperature as a greenhouse must have. In a house with a northern aspect, and carefully regulated as to temperature and ventilation, grown by themselves, they will do well; and even, as Mr. Low has proved, many sorts that have languished under other treatment have thriven under this. Various points in the cultivation of Orchids, as in other plants, are only arrived at by constant attention and knowledge of the different kinds, each, it may be, requiring its own special method. Thus with *Calanthe* and *Limatode*, it has been a customary plan, when the leaves drop, to lay them on one side; but, this according to Mr. Low's ideas, is all wrong. He keeps them growing, as it is then that the flower-buds are produced. What a charm, too, in these fine winter-blooming Orchids of which, as they bloom, the spike lengthens until it reaches 3 or 4 feet in length! How deliciously sweet-scented, too, are some of these flowers! *Dendrobium hedyosmum* (well deserving its name), for example, one bloom of which would scent a whole house.

But we must pass away from the Orchids and look at these ranges of pits. Hundreds and tens of hundreds of young plants of *Erica*; pots full of young *Conifers* of the rarest kinds in myriads; and in the houses range after range filled with the winter and spring-blooming *Heaths* in flower. A curious fact Mr. Low mentioned with regard to these—viz., that the hot September had so hurried on the blooming season that *hienalis* was nearly over; and *vernalis*, which should not have been in bloom till February, was now all coming into bloom. These plants are dispersed all over the country. They are killed by tens of thousands every year in London drawing-rooms, are hawked about by itinerant vendors in the suburbs, and hence there is a never-failing demand for them, and a never-failing supply.

Camellias are here by the thousand, Mr. Low importing every year a very large number from Ghent, that city of *Camellias*, and also growing a large quantity of his own working. With regard to these latter, he had been adopting a plan of his own. Instead of allowing the top bud to grow out and make the young wood for the new year, he cuts off that bud, and by that means induces the third and fourth eyes to push their buds forth, and thus to make a more bushy and stably plant. This system seemed to be answering well, as the plants were looking well and vigorous under the treatment.

The splendid tree Ferns belonging to this establishment were so much admired at the Guildhall that it would be needless to say anything about them, save that Mr. Low was adopting a curious plan with some of the stems which had come home dead—namely, following out the top, and placing a young plant in the crown of the stem.

We can see here what changes railways, especially in their improved system of communication, are making in everything. Mr. Low was sending a large quantity of greenhouse plants away to the north of Scotland. Instead of mats, baskets, &c., and all the expense and trouble connected with it, they were being conveyed in waggons to the Great Northern Railway, where a truck or more is placed at his disposal; the plants are packed in this, and they reach Aberdeenshire without even a change of carriage. Where the consignee lives near the station this can be easily managed, and the plants sustain no damage, while the saving of expense is very great. Thus in one way or another I was picking up during these two hours much interesting information, learning something fresh, and also to admire the zeal and energy displayed by our great plant-merchants. The depth of winter is not usually a good time for visiting gardens, but I have found out that at all times something is to be learned.—*D., Dal.*

GOLDEN VARIEGATED GERANIUMS.

I FIND that these varieties have disappointed expectation in several places, owing, I doubt not, to the unusually dry hot summer, along with sudden transitions of temperature, nights being chilling, and days scorching. However, there is one peculiarity in these *Geraniums* which has arrested my attention—namely, a deficiency of fibrous roots compared with other bedding *Geraniums*. This deficiency, I think, in a great measure prevents them making equal growth with others of much stronger constitution, and of which the roots are in proportion to the growth of the branches, for it is evident that

unless there be reciprocity between root and branch little progress will be made. Here the Golden-variegated *Geraniums* have done very well, although the season has been unusually warm and dry; they have afforded a good supply of cuttings, and will give many more in spring if wanted. I would advise the inexperienced to have their plants well established in pots before planting, as this is very conducive to success in the growth of this class of *Geraniums*; also, not to plant out too soon. If good plants are in store they will at once give effect, while small plants turned out too early, will throughout the season disappoint the expectations which have been formed of them.

I offer these remarks to the inexperienced, not to those who can judge for themselves. Many bedding plants may be turned out from store pots and boxes, but the Golden-variegated *Geraniums* will not succeed under that mode of treatment.—*JAMES REID.*

ROYAL HORTICULTURAL SOCIETY.

MONEY PRIZES SUBSTITUTED FOR CERTIFICATES AT SATURDAY SHOWS.

At the Meeting on Saturday last Mr. George Ward, gardener to T. N. Miller, Esq., of Bishop Stortford, exhibited two very handsome Smooth-leaved *Cayenne Pines*, which weighed 7½ lbs. and 7¼ lbs. respectively. They were awarded a first prize of £1. We take this opportunity to state that the system of awarding certificates, as was done last year, has been abandoned, and money prizes instituted instead for meritorious subjects exhibited at these Saturday meetings. These meetings will be continued throughout the year, and schedules containing the details of subjects invited may be obtained on application to the Assistant Secretary at South Kensington.

WEATHER WISDOM.

(Continued from page 526.)

My former remarks on this subject were written with the view of directing the attention of your readers to a more careful and regular study of the barometer, in order to enable them, by noting down at fixed periods its various changes, to anticipate to a certain extent probable weather. Many persons are fully alive to the various causes which produce the rising and falling of the mercurial column, and they, I am sure, do place reliance upon the weather-glass. That dependance is very often severely tried by the apparent waywardness of the mercury. The column will remain high when the weather seems to say, "You ought to be low;" and the barometer will show a great diminution of atmospheric pressure when the sky is calm and serene. But persons more advanced in the pursuit of the knowledge of the science of weather go deeper into the subject. They know, and experience teaches them, that though bad weather was not actually present at the particular spot where the barometer was observed to be low, yet a gale has been raging not many miles distant. The barometer, he it remarked, is a very delicate instrument, and is affected not only by the atmosphere immediately above the locality of observation, but by the great atmospheric waves which are sweeping at a distance over the surface of the surrounding country.

To those of your readers who are but imperfectly acquainted with the real cause of the rise and fall of the mercurial column I would now particularly address the following remarks:—Whenever there is an invisible agent at work persons are apt to be sceptical. Every one knows how the mechanism of a clock or the hands of a watch are set in motion; there is the weight, the spring, or it may be other causes. It is reasonable to suppose that some result will follow the adaptation of the different parts. No one wonders at the movement of the hands; but look at the barometer! It is not wound up, and there is nothing visible to cause any motion. Watch the glass carefully during a gale or heavy fall of rain; the mercury falls fast, almost whilst the eye is upon it; and because there is apparently nothing to account for the change they have seen, persons go away disappointed from such a contemplation, and as they do not recognise the hidden power which acts on the column, the instrument is despised. Men will, however, put faith in the correctness of a watch or clock because they know how it is set in motion; but as to the barometer, they say, "It is of no use; its movements are mysterious, and therefore it must be disre-

garded as of no value." Now, the agent which balances and supports the mercurial column is the atmosphere. The earth is surrounded by this atmosphere, weather is constantly changing, and with such changes atmospheric pressures increase and diminish daily and hourly. That pressures do vary, and that the barometer is affected by such variations, can be demonstrated in the following way:—Let any one take a portable barometer to the summit of a hill, having, previously to starting upwards, noted down the height at which the column stands. Suppose the ascent to be 500 feet, it will be found that on arriving at the summit the mercury has fallen considerably. Why is this? Why should there be any change? The reason is as follows: In ascending the height a diminution in the density of the atmosphere is experienced. The atmosphere which at a lower height supported the column of mercury will not support it at the top of the hill. The mercury falls. But let the glass be brought down directly to the original starting point, and the barometer will read once more at the same height as it did at first. To those who are able to perform another experiment, the atmospheric pressure on the column of mercury is more clearly and quickly illustrated. Place a siphon barometer (simply the glass tube filled with mercury) under the receiver of an air-pump; directly the pump is set in motion the column will fall, and will continue so to do in proportion to the rarefaction of the air. Now turn the stop-cock; admit fresh air in the place of that which has been pumped out; what is the result? The mercury returns to its original height.

I am perfectly persuaded of this, that if any one can firmly fix upon his mind that atmospheric pressure is the cause which regulates the oscillations of the barometer, and that during the variations of the weather atmospheric pressures do vary, there would then be more attention paid to the instrument, and persons would try to fathom its movements and to investigate its constant and sometimes apparently mysterious changes. In all scientific researches, however, it must be remembered that man is the being created. Let no one strive to dive into hidden mysteries simply and solely for the purpose of curiosity and self-glorification, or for the purpose of finding out what has been wisely hid from man. On the contrary, let every one so use his knowledge as to enlarge and develop those gifts and resources which have been placed at his command by an allwise and bounteous Creator for his own enlightenment and that of his fellow-creatures.—X., *Surrey*.

THE FRUIT-BEARING AUCUBA JAPONICA AS A DINNER-TABLE PLANT.

ALLOW me to add this plant to the tastefully selected list made by Mr. Robson, for dinner-table decoration. In passing through the Messrs. Osborns' nursery the other day, I noticed some beautiful standard plants of the Aucuba loaded with its bright red fruit, the berries being about the size of medium-sized acorns, in bunches of from eight to sixteen. The plants had nice symmetrical heads about 16 inches in diameter, and clean stems from 18 to 24 inches in length, and half an inch in diameter. Once seen, the fruiting Aucuba cannot fail to be a favourite, and it is a valuable acquisition for decorative purposes. I noticed, also, a number of standard *Laurustinus* of the same dimensions as the Aucubas described, covered with bloom and beautifully feathered down the stems, and which cannot fail to be gems on the dinner-table. Now, if circular pans made of zinc or of any other material were constructed to fit over the mouths of the pots of such plants as described, and these pans were planted with some of the Lycopods—such as *apodium*, *densum*, or *umbrosum*, edged with *caesium* or other trailing Mosses to form a drapery over the edge, with a few *Crocuses* or *Snowdrops* peeping through the green moss, the whole would make a lovely ornament both above and below the "line of vision"—quite a natural *épergne*. The pans should be made in halves, with a circular groove in the centre of each for the stem of the plant, and have two clasps to secure the entire pan.—P. M., *Putney Heath*.

METEOROLOGY OF FRUIT-TREE HOUSES.

I HOPE Mr. Rivers will excuse the festivities of this season having prevented me from replying sooner to his letter; and I may also add that now, when ever one is trying to feel so

happy and saying so many kind things to all the friends he meets, I have no desire in this letter to appear personal. I have often withstood the temptation to put in a smart thing, and also crossed out what I was afraid might be taken for an asperity; but having strong opinions as to the advantages to be gained by sun heat, gathered principally from my own experiments, I thought I would try how they stood the test of public opinion in your paper. Mr. Rivers answered me, and I have been in this manner obliged to make the best defence I could.

A discussion on the merits of houses can hardly be kept from wandering into questions of cultivation. Thus, Mr. Rivers seems to think forced Peach trees should be treated in a different way from those grown during the summer in an orchard-house. I think it is time we had another name for this anti-season cultivation; for with all the modern appliances it is no longer strictly correct to speak of it as forcing a tree, thereby implying that the tree is unfitted to carry a similar crop in the following year. I have often heard gardeners say, "There is no use in this." "I would not go to the expense of that," and "You can grow perfectly good crops without something else,"—how much they can dispense with, depending on the natural advantages of their situation. The first step in aiding nature is the beginning of forcing. When I first began growing fruit trees I was not aware of the important difference between orchard-houses, and thought an orchard-house was an orchard-house; but now I find it is, and it is not. Mr. Rivers tells me mine should have answered, for they never fail with him. I reply I am further north; but he tells me this is no valid reason, as his climatic world reaches to Stornoway. He has not yet told me what sort of a house this is. If it is a lean-to it is not surprising, for a contemporary tells us, "At Culloden House, near Inverness, the middle-season Peaches, such as the Noblesse, ripen perfectly almost every year in the open air." Not a word about protection, and yet some must be used; but sheeting-up a wall at night is not counted. That a low night temperature helps to ripen the fruit and wood, and consequently the buds for the following year, I think I have tried what I could to prove. It is the low night temperatures in spring and summer I want information upon, and if there is a successful span-roofed orchard-house north of the midland counties in which there is only a single row of four-inch pipes round the house, and where ventilation is given as Mr. Rivers directs. In the "Orchard-House," Mr. Rivers says he cannot ripen November Peaches, but he can October. Should I, then, be told in a polite way that I mismanage mine if, by reason of my climate being worse than his, I am obliged to resort to the treatment he advises for these late Peaches? At page 93, under the head of "Clingstones," I find, "We shall by this mode of culture imitate the warm autumnal nights of the southern United States, and keep the fruit in a growing state till the ripening period arrives. In a common orchard-house without fire heat the cool nights in September seem to put the trees at rest, and the very late Peaches, as I have experienced, do not ripen well." After again reading this, the only conclusion I can come to is what I said in my second letter, which provoked Mr. Rivers—that in the case of trees treated as mine were, that is, exposed to a night temperature in July of 55°, and in August of 45°, they will go to rest, notwithstanding a high day temperature.

Vines require a higher temperature than Peach trees to enable them to perfect their fruit, and I think my letter in the Journal of December 12th will not bear the construction Mr. Rivers puts upon it. I certainly never intended to convey that it was my opinion that Black Hamburg Grapes would ripen better on an open wall than under glass, much less was I speaking of their relative chances against spring frosts. I will repeat what I said: "Can any one tell me what advantage a south wall has over a narrow span-roofed house, from having taken its maxima and minima for a summer in a meteorologically favoured place? I would rather have my Grapes or Peaches, if I wished them to come in soon (early), resting against such a wall, and enjoying its radiation all night long, than be starved in an orchard-house with a temperature of from 40° to 45°." Upon this Mr. Rivers proceeds to argue, but I am not able to say if the figures he gives are the temperatures of a south wall or of the open air; however, as he takes up the subject seriously I am not unwilling to consider it also. He gives from 100° to 120° as the maximum of a south wall in May, and we are then to suppose that the air goes down to 26°. How near will night radiation bring the temperature of the wall to the atmospheric point? I cannot answer the question.

I will now compare a narrow span-roof with this. The average maximum for Chiswick last May was 69; to this I will add 15, making 84. The minimum will be 5 above the atmosphere, or 31. I cannot give the temperatures of a south wall for the months of June and July, and so will pass on to those of August and September, which are given as the same as May—from 100 to 120. The average maxima for these months at Chiswick were 71 and 78; if I add 15 it will make 89 and 93, which should represent the day temperatures of these months in a small span-roofed house. I will now try to compare the nights. Mr. Rivers says, "But radiation during the long nights" (not during these months) "tells forcibly, so that in the morning the 'tender mercies' of the wall have not prevented the thermometer from going down to 45 or 40." Does this mean that radiation has carried off all this extra heat? At Chiswick the average minima for last August and September were 46 and 45 respectively; the night temperature in a narrow span-roof I do not know. A thermometer with a black bulb exposed to the sun rises 50 above the atmosphere in the shade, and often goes down to 15 below it in the night. I should very much like to know if it was owing to this latter cause—extra night radiation, that prevented the experiment mentioned in the "Theory of Horticulture," blackening garden walls, from being of any advantage. But this has no reference to our present subject—we are not discussing the relative radiating powers of colours; and a black bulb to a thermometer,

having no substance to retain heat, is soon cooled. How is it with a thick wall that has been heated to 120? I notice the explanation that the trees in the hedge house are retarded by the cool night air rushing in, which in this case counteracts the advantage of radiation from the soil. Will not a narrow span-roofed house, with the ventilators open at each side, be retarded in the same way?

Mr. Rivers is surprised that I should have given the heat of his large house as 96, for at 5 feet from the ground it was only 88; but this, he said, "was under a dense shade;" in his letter of October the 10th he said it usually ruled 10 to 15 above the open air, which he gave as 80; again, in this last letter he says a span-roofed house 18 feet wide, the sides of which are formed of hedges 2½ feet high, at 5 feet from the ground averages from 15 to 20 above the open air. I did not intend to misquote.

I hope Mr. Rivers will be able to obtain some information upon the climate of New Jersey. I do not know how he acquired his impression that Mentone has a moist climate. Dr. Bennet says that, according to his experience, the average number of days or nights during which it rained little or much at Mentone was 80, at Torquay 155, Greenwich 155. I wish Dr. Bennet could be induced to give us a little more information on these subjects, including the heat of the soil as the Vines start.—G. H.

A WINTER AND SPRING FLOWER GARDEN.

A WELL-KEPT garden is the best ornament the outside of a house can have; it promotes health, and in it one can contemplate the goodness of the Maker of all things in administering to the various requirements of man. There are no associations stronger than those connected with a garden. Let a

man be a thousand miles from home, still his mind will at times revert to and haunt, as it were, his old favourite spots. To strengthen, then, those fond links of home, let us try and make home more interesting, cheerful, and gay, especially in the dreary months of winter and spring.

To lay down a definite rule respecting the extent and arrangement of a flower garden would be a most difficult matter, as no two places are alike. It is necessary, therefore, to exercise great judgment in the formation of a garden, and the designer should not be wholly guided by his own fancy; the size of the mansion should be taken into consideration, for a small house and a large garden never correspond well, and everything about a place should be as nearly as possible in proportion. Another matter to be taken into consideration is the means at

command to supply plants enough to furnish the garden, because it is much better to have a small garden well kept than a large one ill-kept. In a garden, as in any other place, there should be "a place for everything, and everything in its place," and in endeavouring to carry out fully this old saying, I have designed a plan well adapted for a small place, and especially for the front of a suburban villa, where there would be room enough for the design and a good wide border at each side for herbaceous plants, or, otherwise, a grass verge. By

looking carefully over the plan, it will be seen that all within the outside line of Box can be made one mass of beds, at the discretion of the owner, and each bed complete in itself. They can be filled with different plants and bulbs all the year, so that the plants in one bed will not interfere with the arrangement of the bulbs in the other. *l l, m, n n n n*, and *g g*, on the plan, also the narrow alleys all round, marked *x x*, are intended for colouring-materials; they are equally eligible for bulbs, Pansies, or the like. In order to give an idea of how it might look, I will suppose it to be planted with the following plants, which are all easy to procure:—*a a*, white Arabis, edged with blue; *b b*, Alyssum saxatile, edged with Stachys lanata; *d c, d c*, Arabis, edged with Cerastium tomentosum; *e e*, Skimmia japonica; *f f*, Vinca elegantissima; *l l* and *m*, blue Pansy; *h*, Arabis lucida variegata; *g g*, double Daisy; *o o*, common gravel; in the alleys round the two centre figures broken bricks; in the alley round the outside I would put burnt flint (pure white), and in the circles coals. There are many who will not coincide with me on this subject; they are prejudiced against the use of such materials, because, perhaps, they have seen it carried to excess in some places, but anything in excess is distasteful to the eye. I would like to see the objections more fully explained in the columns of THE JOURNAL OF HORTICULTURE, and I should be glad if those who agree with me as to the use of coloured materials, would suggest any improvement that could be made, so that we might be able to learn various opinions on the subject.—M. O'DONNELL.

PRESERVING OUT-OF-DOORS GRAPES.

I HAVE sent you a specimen of our out-of-doors Grapes, also the glass cylinder. 7½ inches high by 5 inches in diameter, in which they were grown.

I believe it is a very old plan, but out of fashion I suppose, as I have never seen any notice of it in THE JOURNAL OF HORTICULTURE. It is a capital mode of keeping out-of-doors Grapes for late use. The oiled calico protects them from rain, and the perforated zinc keeps out birds and insects, but admits sufficient air. The Grapes were thinned when about the size of Peas; the glasses were put on immediately, and, except pruning, no attention has been given since.

The glasses have been in use here for many years with oiled calico bottoms, and shaded with limewash, but the Grapes became mouldy soon after they were ripe, and if holes were left for ventilation the wasps and flies soon finished them. I adopted the zinc bottoms two years ago, and the glasses have done very well since and require no shading.—JOHN JONES, *Gardener to Col. Gladdish.*

[The bunch of Grapes, Royal Muscadine, were in very excellent condition (January 2), but slightly shrivelled, and not at all mouldy or deficient in flavour.—Eds.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

As the weather has been particularly open and mild up to this time, all trenching, rough digging, gravelling walks, &c., ought to be pushed on as fast as possible. Where drainage is necessary, now is a good time to execute all work of that description. When we see the agricultural world so alive to its benefits, it is strange to hear gardeners, like fatalists, lamenting over their pining Peach and Nectarine trees and bad crops, and making no effort to strike at the root of the evil. The very worst soil and situation may be improved by drainage. *Asparagus*, the beds should be soiled or manured as soon as the frost makes the ground hard enough to bear wheeling. *Beans*, sow another crop of the Mazagan, and plant out any which have been hardened off after being germinated in heat. *Carrots*, sow a moderate breadth of Early Horn, also Short Top Radish; there is no better plan than sowing them in drills alternately, covering in with sandy matter, and protecting with any available material. An excellent method of fastening down such material is to place long willow rods at convenient distances, pegging them down at each end with a strongish hook. *Cucumbers*, the plants in houses must be strictly attended to, to keep them in health; refrain from removing or injuring any of the leaves, if possible; guard against over watering, which is particularly injurious in dull weather. Prepare dung for the main early beds, and make a small seed-bed for raising the plants. *Cauliflowers*, those under hand-lights require constant attention, keep the surface stirred, dust with lime and charcoal dust; an excellent plan to catch slugs among these is to split large Carrots and lay about the plants, by picking them on mild mornings an immense number may be taken. See that the hardy varieties of *Lettuce* and *Endive* on banks or borders are properly protected, and look over the plants in favourable weather, removing decayed matter, and covering up for blanching when dry. *Peas*, make a second sowing on a warm border. Waite's Daniel O'Rourke and Early Warwick answer well for this sowing. Be careful to keep a good number of figure-4 traps constantly set, there are none better for keeping down those destructive pests, the mice. Peas coming up must have the surface soil constantly stirred, and opportunities should be watched for the destruction of slugs by dusting with quicklime. Endeavour to keep well up with all work in this department, the time is fast approaching when we shall find the advantage of having done so.

FRUIT GARDEN.

Proceed with planting, and the necessary arrangements for planting where it is not already brought to a conclusion. Prune and nail wall trees; dress those fruit trees that are infested with moss, lichen, or scale, in suitable weather; prune, train, and tie in neatly, all espalier trees, and carry away all refuse that will not readily decompose to the char heap, there to be converted into valuable manure. Fork among all fruit plantations, applying some manure, if possible, about the roots of the trees. Peach, Nectarine, and Apricot trees should be protected in due time with spruce boughs, or some other material. If frost prevails stir up the soil well with the hoe or fork close under the walls and fences, such places afford a ready refuge for slugs and other vermin. It is not a bad plan to shake a little quicklime over the earth thus disturbed.

FLOWER GARDEN.

During fine weather, like the present, continue to dig the borders where this has not been already done; edge and clean walks, lay turf, and make edgings good where that is necessary. In favourable weather keep all hands busy out of doors, leaving in-door jobs for bad days. Plant shrubs, and regulate herbaceous plants; reduce Phloxes, &c., when they require it, and replant them after well digging the ground; take care not to plant too thickly, and leave room for planting tender plants in spring and summer. See that all half-hardy plants are secured against severe weather.

GREENHOUSE AND CONSERVATORY.

As the conservatory is the chief place of resort for the family in winter, it is requisite that the flowers, &c., be at all times kept particularly clean and dry, dryness of atmosphere through fire heat will not, however, keep the plants in that luxuriant health, which not only creates a present interest in them, but also furnishes a guarantee for success in future. Great moderation, therefore, in the use of fire heat is necessary in this department, more especially in the dead of winter. A tempe-

perature of from 40° to 45° by night, and from 50° to 55° by day is at this period amply sufficient. A temperature of 50° by day and of 45° by night is sufficient for the greenhouse at present. Keep the Pelargoniums in a quiescent state, give as little water as possible, in fact, none, unless the plants show a disposition to flag in the leaf. Abundance of air is requisite, avoiding, however, cold currents, which are very liable to spot the leaf when in a tender state, through close confinement. Keep all Cinerarias, Heliotropes, Calceolarias, and other softwooded plants, &c., in the lightest part of the house, and as near the glass as possible. Correas, Epacris, Heaths, &c., should be placed on a bench by themselves in the most airy part. Examine daily every flowering plant, remove every decaying flower as it appears, and see that the foliage of Camellias, Rhododendrons, Oranges, and similar plants is perfectly clean. The contrast produced by the fine, clean, large leaves with the numerous blossoms, at this season especially, gives a relish for such houses, and renders them doubly capable of yielding enjoyment.

FORCING-PIT.

This pit should have a permanent bottom heat of 80°, with atmospheric moisture. Such being the case preparations must be made for securing a due succession of early spring flowers; if not already done let a sprinkling be introduced of the most popular tribes adapted for forcing-purposes, such as Persian and common Lilics, Azaleas, both hardy and Chinese kinds, Lily of the Valley, Hyacinths, and other bulbs, *Acacia armata*, *Epacris*, and the various kinds of Pelargoniums suitable for forcing, hardy and Nepal Rhododendrons, Daphnes, Dentzias, &c. The new Hybrid Roses will do better in a more moderate temperature, with the exception of the Teas, which will endure a lively heat. As these plants in general require a moderate top heat in proportion to the bottom heat in the earlier stages of their forcing, they may be kept together at one end, and receive more air in mild periods. The other end of this pit, kept closer, will be eligible for such plants as *Thunbergias*, *Gardenias*, *Fraxineas*, and numerous other plants that require more atmospheric moisture.

STOVE.

The season is not yet sufficiently advanced to allow of an increase of temperature. A steady heat ranging between 60° and 65° may be sustained, if the weather continue open. The occurrence of frost will demand a reduction of temperature. Allow the thermometer to sink at night. Artificial heat without light, as has often been explained, is injurious to vegetation. Recollect always that stove plants, as well as others, require fresh air. The stove may still be gay with the beautiful *Gesnera zebrina*, *Euphorbia*, and *Begonias*, which outvie the gayest plants of summer in brilliancy and beauty.

PITS AND FRAMES.

If the tenants of these have been housed somewhat dry, and kept so, and hardened with abundance of air, nothing is necessary but to follow up these principles, and to take care to exclude frost; if, however, severe weather should occur, and they become frozen, see that they are not uncovered directly a thaw comes. Let them remain in comparative darkness until they are quite thawed, which in ordinary cases will be about two days, merely turning up the mats or straw a little at both back and front, so as gradually to inure them to the light. Examine your stock, and such plants as you are short of should now be placed in a gentle heat for the purpose of exciting their growth for cuttings. *Anagallis*, *Verbenas*, *Petunias*, *Salvias*, &c., should now be brought forward for filling beds and borders in summer. Be sure that you have enough of these. Give abundance of air in mild weather to cold pits both night and day, and withhold water from the plants at this season. Prepare soil for potting-off stove plants. This might soon be commenced.—W. KRANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

VERY much the same as in previous weeks, with the exception of potting a lot of Potatoes that had pushed several inches long, and filled four and five-inch pots with roots, placing two of these pots in 12 and 13-inch pots. From these we generally gather rather earlier than from those planted in beds, with a little heat below them, and as they approach perfection they can be placed anywhere under protection, and the room they now occupy in pots can be devoted to other purposes. A quicker way still is to place a single plant in a five or six-inch pot, plunge it in a mild heat, and as the top grows earth-up

with rotten leaf mould. The curbing of the little pot causes the tubers to form and grow sooner than when they have more room.

Rhubarb put a few more roots into the Mushroom-house, with a little bottom heat from leaves, &c., and the top temperature is from 50° to 60°, as that brings on our Mushrooms as fast as we want them for use, at present every day; but we will send in the latter more seldom, if more at a time, as it is rather out of our way to make anything too common. Give even *Rhubarb* and *Sea-kale* every day, and either will be less valued than if given, say, three times per week. The same as to *Asparagus* at this season. Send it to the house every day, and it will soon be no more thought of than it is in May. Of course when there are particular parties the matter should be different, and if the gardener knows the number of days the party is to last, he will try and send the best and the greatest variety. A great many employers are never the best served when they have visitors, because they never condescend to let their gardener know anything of their intentions, and therefore nothing is sent in but what they would have had in the usual routine. For want of the gardener knowing anything of such matters, we have known many instances where rarities and delicacies for the season were sent in every day to the usual family dinner, and then when there was a particular party there was nothing rare to send. Those employers only will be the best served who give due notice of such matters; without that notice they must be satisfied with what the day will produce. *Rhubarb* has been plentiful enough since Christmas. We feel obliged to "R. F. Liverpool," page 3, for what he says on the subject. We agree with him thoroughly as to what he says about a high temperature for this or any other vegetable that comes to maturity in a comparatively low temperature. We corroborate also what he advances about darkness being an advantage for the earliest crop; but after the middle of this month *Rhubarb* will come on anywhere in light, where there is the requisite heat to excite it into growth. For the earliest we find placing a box or pot over it, as well as a mild heat beneath it, useful either in the Mushroom-house or any other suitable place. We are well aware that to have it early in winter it will come better if grown rapidly in the early part of summer, and encouraged to stop growing by dryness in autumn, so as to lose its leaves and go to rest sooner, for the sooner it goes to rest the sooner will it be easily excited into growth; but what we chiefly referred to, and to which our correspondent alludes, is the difficulty of bringing it in as quickly as *Sea-kale* or *Asparagus* at an early period. Before Christmas, in similar circumstances, it often requires double the time that either of these do, whilst after the new year it requires but little more time than they do. Either of the latter can be had very good in three weeks, before Christmas, though a month and milder heat will often give stronger and sturdier gatherings. In the case of *Asparagus* we shall fill another light, the roots for which we have kept in reserve; but as the lights of the frame were not of good glass, and the weather has been so dark, we have gathered the *Asparagus* and set it on damp moss in a house commanding more light, to make the heads greener before going to table.

FRUIT GARDEN.

Looked over the fruit-room, removing any specked fruit. Placed Strawberry-pots on shelves in pits where there was any room to spare. Looked over Grapes for any damping berries; damped the wood of Vines breaking in a small pit; top-dressed trees in pots in the orchard-house; prepared some litter for covering outside Vine-borders, formerly merely protected with a little stubble; covered-up the border outside of the Peach-house, where fires have now been lighted, and damped the wood several times in the day. The pipes have been fresh painted with oil and black, but the smell will be all gone before the heat will be at all strong. We notice that some recommend painting the pipes when they are cold; but if there is not much tender in the place we prefer painting the pipes when hot—say when at a temperature of about 120°, as then the paint goes on much thinner, and dries more quickly. It is best to do all this painting when the house is empty, as the effluvia from the oil are dangerous to many tender plants.

ORNAMENTAL DEPARTMENT.

Were we to enter into detail we should merely repeat about plants, &c., what has been said in the last and some previous weeks. From our own practice it may be more useful just to refer to a few matters.

1st, All *Bulbs* and *Hardy Shrubs* will be forced more easily now than they could be before Christmas. Hardy bulbs, or such as

are called bulbs, as Winter Aconites, Snowdrops, Crocuses, &c., are the better of having only a little extra heat given; Hyacinths and Narcissus, after the pots are full of roots, will stand more; Tulips will go between the two. From 45° to 50° is quite enough for the first, from 55° to 70° for the second, and from 50° to 55° and 60° for Tulips. Hyacinths will rise more freely if a funnel or a pot is placed over the flower-stalk just after it has shown, and a mild bottom heat will assist them, and a little manure-watering as the stem rises. When wanted to bloom in glasses, and not to be grown in glasses, we know no better plan than, just when the first flowers of the spike are opening, to take the plant out of the pot, and wash away all the soil carefully with the hand in a pail of water at 70°, turn the roots carefully into the glass, and if the glass is coloured so that the water cannot be seen, put in a few nodules of sweet dried cowdung, and as many more of little bits of charcoal, fill with water at between 60° and 70°, and change every three days or so. When we used thus to manage with coloured glasses, a pinch of superphosphate of lime, as much as could comfortably be taken between the thumb and finger, placed in the water each time it was changed, would add to the size and strength of the sweet bells. A similar dressing twice a-week would also be useful, spread on the surface of the pot before watering. Sheep or deer dung collected and kept dry to sweeten for two or three months, and then hot water, when near the boiling point, poured over it, say twelve gallons to a peck, allowed to stand for forty-eight hours, and then the clear liquid used in watering, alternately with clean water, will do much to strengthen the flower-stalks; but this liquid must not be used oftener nor stronger, if regard must be had to fine distinct colours in the flowers.

All hardy shrubs, as Rhododendrons, Kalmias, Roses, and Lilacs, will do better if they have been well grown so as to fill the pots in summer, and obtain a mild bottom heat now, and from 50° to 60° top heat, with a rise in sunshine, the syringe being freely used in fine bright weather to soften the buds. When the bloom begins to open the plants must be hardened off by degrees, so as to stand in cooler places, as greenhouses. Hardy Azaleas and Chinese Azaleas require similar care, both before and after they are in bloom, bringing them on gradually and hardening them off gradually. Many a Chinese Azalea well supplied with buds will throw these buds when taken at once from a temperature of 35° and placed in one of 65°; whilst if it had obtained a few days at 45°, a week at 50°, another at 55°, and so on, all the buds would have opened kindly.

2nd, *The importance of regulating temperature in proportion to light.* If in such dull weather as we have lately had we give a high temperature to lots of comparatively hardy plants, we encourage weak sickly growth, which is almost sure to be attacked with insects. Hence the constant advice, Smoke with tobacco at least once a-week, in order to keep all right. We sometimes wonder what sort of an amount a year's consumption of tobacco will thus come to. A lower temperature, when there was little sun to consolidate growth, would have prevented this being weakly, and saved many pounds of tobacco. Besides, that is not all: tobacco is dangerous when growth is tender, and the foliage or flower-stems are at all damp. We have looked at half a dozen sad complaints of herbaceous Calceolarias and Cinerarias being next to destroyed by smoking them for green fly; whilst with the mild weather we have had this winter, provided these plants had been cool enough and moist enough, and therefore allowed to grow more slowly, there would have been no green fly to destroy; at least it seldom appears in such circumstances.

3rd, *Transplanting Trees and Shrubs.*—We have pretty well finished the most of what is to be done in this way at present. From a passing remark made on transplanting shrubs, &c., two inquiries have come to us soliciting an answer here. First, "What sort of a thing is the low-wheeled truck you speak about?" We have some waggonettes here, chiefly for moving plants, and which average 5 feet long, 2½ feet wide, with sides and ends 6 inches deep, furnished with a handle on a swivel, and two axles and four wheels, each 9 to 12 inches in diameter. Thus mounted we call them "go-shores." The sides and ends are fastened to the stout floor with bolts. When we use these for transplanting rather heavy shrubs with a ball, we take off the sides and ends, an inclined plane is made after the shrub has been undermined, and one end of the platform truck is brought under the shrub, and with the help of levers the truck and the shrub are got out of the hole, and if the ground is not very soft, and there is

enough of strength, the shrub can be taken anywhere. The second inquiry has reference to "the transplanting a lot of young Oaks growing in an unsuitable place, in good loamy soil, trees from 20 to 35 feet in height. The place they would be taken to is rather more exposed, but the ground equally good. Must be moved this year if moved at all, otherwise be grubbed up. Would be anxious to move them, but do not know how to go about it. Can give a horse, but will not be at the trouble or expense of obtaining a transplanting machine, with strange people to manage it. Must have it done, if done at all, with my own people, with such machinery as they can improvise for the purpose." Well, we have helped to move many such trees without any machinery at all, and thus we proceeded: We dug down a circular trench from 6 to 8 feet from the bole of the tree, according to its height, traced out the roots, and picked away the soil pretty well up to the bole, and then had the earthless roots and the tops carried to the place where an equally large hole had been prepared, and after having the tree set upright, after neatly shortening-in the branches, packed the roots firmly and nicely with the new soil, and if rather damp gave no watering until March, but if the soil was dryish watered when all the roots were packed. After allowing time to settle—that is, whilst another tree was being planted, then the rest of the soil was placed on, and beaten firmly, except a little loose soil left on the surface. A basin was also left in case the summer should be very dry. Such trees would require securing from wind, either by three poles, or better still, by three ropes, or three chains fastened to a collar put round the stem of the tree, and attached to three stout stakes or poles, put at equal distances 8 or 9 feet from the bole. Under such circumstances as those alluded to, however, we would proceed a little differently. We would dig the trench as above, and proceed with disentangling the roots until we came to within 20 or 24 inches of the bole, we would then undermine the ball pretty well all round. We would then procure a stout timber gig, consisting of a stout axle-tree with a wheel at each end, and a stout pole to work at pleasure in the centre of the axle-tree. We would wrap a mat or two round the ball, make an inclined plane for the wheels, one of these to go down on each side of the ball; wrap a mat with some straw, &c., round the bottom of the hole of the tree to prevent grazing the bark; set the pole of the gig upright, against the hole of the tree; bring a stout iron chain from the axle-tree to go underneath each side of the ball, and fasten that tightly and securely; brace the pole of the gig and the bole of the tree firmly together, placing some litter between them to prevent grazing the bark; then attach a chain to the top of the pole, and long enough that when the other end was attached to the horse-tackle the horse would be far enough from the top of the tree when it came down. A steady pull, with the help of some leverage, will bring the pole and the top of the tree down, and raise the ball, hanging from and behind the axle-tree; another pull and a little leverage will take the wheels out of the hole, and a little on to solid ground. Then unhook the horse, have some men to keep the top of the tree right, and connect the horse with the axle-tree behind, when the root end will be brought to its destination, men looking after the top all the time. It is easy to bring the root end just over the centre of the hole, and when the top is set upright the pole may be removed from the hole, all chains unfastened, and the packing proceeded with. Though this mode requires more moving-power, yet, if well done, and the trees are not larger than stated, the ball thus secured will keep the tree secure in its place without the assistance of ropes, stakes, or chains. Two other points had better be attended to: First, never let the tree be deeper planted than it was at first; and, secondly, when removing from a warm to a colder place, some small hay-bands, or straw-bands, should be twined round the bole and principal branches, not close together, but with openings between; and this, if the bands are made loose and rough, will help to keep the trees warmer, and will also keep the bark moister. The same remark as to watering will apply as in the first mode noticed. We have known transplanted trees perish from nothing but keeping the roots in a morass. To prevent this, in all stiff soils the subsoil, if not taken out, should be well picked to allow excess of moisture to escape freely. When the soil is kept wet about stagnant roots it just ensures extra cold, whilst we should wish the soil, if possible, to be warmer than usual. The roots will push sooner when the soil is neither wet nor dry, and a little water when the buds push will be more important than much deluging now. A little lightening of the heads, so as to lessen the surface of evaporation, will also be useful; but it will be wise to do it neatly, and to cut back to

strong prominent buds. Of course McGilshan's machine would make short work of such planting; but even with the above materials, if men do the first tree very carefully and nicely under your superintendence, you must not think much of the time, as every fresh tree they go to they will move more rapidly and better. The chief advantage of such transplanting is that the trees make a show at once. They generally require a couple of years or so to get into full growth.—R. F.

COVENT GARDEN MARKET—JANUARY 6.

We have again to report abundant supplies with little or no alteration in prices. Our first consignments of Salads from France have come to hand, but at present are not much better than home grown.

TRADE CATALOGUE RECEIVED.

Lamoureux, Clark, & Co., 4, Cornwall Street, Plymouth.—General Price Current and Garden Directory for 1866.

TO CORRESPONDENTS.

GRAFTING MASTIC (See C. C. E.).—We do not know where it can be obtained, except of M. L'homme Lefort, Belleville, near Paris.

REPAIRING PAVISH ROAD (Index).—You must consult a solicitor. There are usually local as well as the general statutes to be considered.

STOVE WITHOUT FLEA (P.).—The stove you mention would give sufficient heat for your small greenhouse, but the fumes from the fuel would injure the plants. We recommend you to have a small gas stove, with a tube from its top passing into the open air. We used one for years.

WASHES FOR WALLS AND WALL TREES (Mr. N. F. C.).—For the walls take fresh lime and soot in equal proportions, mix to the consistency of whitewash with boiling urine or liquid manure, and apply the wash hot, the hotter the better, to the walls, brushing it well into the holes and crevices. For the trees, take of soft soap, 8 ozs.; sulphur vivum, 1 lb.; and fresh lime, 1 lb. Dissolve the soft soap in a gallon of strong liquid manure, add the sulphur and lime, and mix thoroughly, then bring to the desired consistency by adding clay. Apply this mixture with a brush, rubbing it well into every crack, hole, and crevice, and being careful to coat but not to brush so heavily as to rub off the buds. The earlier it is done the better.

BLACK DAMASK PLUM AS A STOCK (Albion).—This Plum, recommended by Mr. Rivers as a stock on which to graft Peaches, Nectarines, Apricots, and other Plums, is the Damas noir of the French catalogues.

CHINESE PRIMULAS (A Reader).—White-flowered Chinese Primroses with red-leaf stalks are not unusual.

INSECTS IN OAK FLOOR (Yorkshire).—The insect in question is the common Anobium tessellatum. If the oak floor were soaked with a saturated solution of corrosive sublimate, the larvæ would be killed.—W.

DISCHARGING A GARDENER WITHOUT NOTICE (A Constant Reader).—If you received your wages weekly a week's notice will be sufficient, and your house, if rent free, being really part of your wages, must be quit after the same short notice. You can recover those wages and some compensation for the house if turned out and away without a week's notice. You say certain charges are brought against you; of these we know nothing. If you have not been faithful you are not entitled to any notice.

ORANGE AND CITRON TREES UNHEALTHY (Mature).—Your trees will be difficult to recover. Your having them lately taken out of the pots is right, if you drained the pots well, used a compost of light turfy loam, with a free admixture of sand, removed all the old soil from the ball, and cut out the dead roots with a sharp knife. If you did not act thus, do so towards the end of February. About the middle of March plunge the pots in a bath of about 75° with a top heat of 50° by night, and sprinkle the trees overhead twice daily. If you cannot give them bottom heat, then place them in a smery, or, failing that, keep them in the greenhouse with the soil just moist, but upon no consideration very wet, nor, on the other hand, dry, and sprinkle overhead morning and evening with water 5° warmer than the temperature of the house. If the trees bloom, or show for bloom, as they may do, without producing shoots, rub the blooms off immediately they are seen, and if the head be very full of small twiggy shoots, thin these out considerably, leaving only the strongest shoots so as to form a well-shapen thin head. Any old partially dead wood to be removed. Keep the soil moist, but do not water copiously until the young shoots appear, and not then until the soil seems to require it, which is a good sign of the plants having roots to lay hold of it. Mature, whether liquid or solid, is poison to plants without leaves and otherwise sickly. Strong food is only for healthy plants, and yours will not need such for the first year. Do not overwater, and yet keep well supplied after growth has commenced.

ROSES AND LAURELS ON A BANK (S. G. H.).—Your bank would look extremely well if climbing Roses only were planted, but not with Laurels in alternate lines. We would have it all Roses, or all Laurels, either of which would look very well, and, if anything, the Laurels would be the finer of the two, as they are so much more attractive in winter. Whichever you have, and you can have either according to your taste, the plants should be pegged down, the Roses now, during mild weather, and the Laurels in spring. If you have all Roses peg down the strongest shoots, as they will best cover the surface, and do not prune them beyond cutting out the very weak shoots. In future years all they will need is to be gone over in summer to cut out any old and straggling shoots that spoil the general effect, pegging these down instead of removing them if the ground is not sufficiently covered. In autumn, or from that season to spring, they should be looked over, and the old shoots that have flowered and are weak cut out, young strong shoots being pegged down in their place. The effect of this bank of Roses will be excellent in June and July; but at other times it will not be great. A dressing of manure when the shoots are regulated in autumn, before pegging them down, will do them good, it being neatly pointed in. If Laurels be preferred, peg down the shoots in spring before they begin to grow, spreading them out so as to cover the surface. If the shoots are produced in sufficient numbers to cover the surface, cut them in in June to within 6 inches from the ground; but if not, let them grow, and in autumn or spring peg them down, and so on annually until the ground be completely covered. When that is the case prune them early in June so as to keep them low, and go over them once or twice during the summer, and cut out irregular growths so as to produce a close, even, sloping surface. A slope thus covered is one of the finest ornaments in a garden, always looking well, and many an ugly bank may in this way be rendered ornamental.

PREPARING CLIMBING DEVENENSIS ROSE (Idem).—Prune it next March. Be content with cutting out the old, weak, and ill-placed shoots, and train so as to allow them plenty of light and air. If the plant is weak cut it in to six eyes.

PELARGONIUMS TO BLOOM IN AUGUST (A. R. M.G.).—We presume that your plants have already been stopped, but if not do so at once, by taking out the point of each shoot at the third leaf; but if they were cut in late, as we do those for late blooming, they will not as yet require stopping if they have been kept on a shelf close to the glass and just free from frost, with air daily. You cannot keep them too near the glass, or too cool, if only frost and damp be guarded against, nor give them too much air. When the shoots have made three leaves stop them, repeating this proceeding up to the first week in April, when they should be stopped for the last time. When the plants have broken after the last stopping, remove them to a cold pit, and stand them on an inverted flower-pot so as to be not further than a foot from the glass. Train out the shoots as they grow, tying-down or otherwise regulating them so as to keep the head open and evenly balanced. Give all the air possible by tilting the lights, and protect at night from frost by a covering of mats; and by day a thin mat thrown over them will do much to retard them, but it must only be used during very bright weather, and for a few hours in the middle of the day. After danger from frost is over draw down the lights on calm nights, and on those when there is no danger of more than a gentle shower of rain, but put them on by day, tilting them high, and shade as before for a few hours during the hottest part of the day, using them at night only to protect the plants from rain and high winds. If the plants are likely to bloom too soon you may, after the trusses appear, remove the pots to a north aspect, where there is no sun from 9 A.M. to 4 P.M., protecting from wind and rain by a frame and lights. It will take six weeks from the time the trusses show till the plants come fully into bloom. Stopping the young shoots late will injure the bloom, but the freshness of the foliage will amply compensate for that. You can hardly have plants in bloom in August by picking off the flower-buds, and doing so will tend to make the plants leggy. Autumn-struck cuttings will make nice plants, but the best are those a year and not more than two years older.

SOWING CYPRESS SEED (Idem).—You may sow it in shallow pans as you propose, in sandy loam, and place them in a cold frame. Plant or pick off the seedlings in the spring of the following year. March is as good a time as any to sow the seed.

CRACKS IN CEMENTED WALL (Idem).—Neither paint nor any other composition will prevent the water oozing through the wall after frost. Your only remedy is to prevent the frost acting upon it, and unless you can do this you must be content to fill up the cracks with cement. If the wall is dry and the cracks are filled with cement, but damp comes through after a storm, then you may coat the wall with boiling coal tar, adding 1 lb. of pitch to a gallon of tar. After filling up the cracks, apply the tar when the wall is dry, or you may give three coats of Carson's anti-corrosion paint, allowing each coat to dry before the other is put on.

IMPROVING CLAYEY SOIL (E. S. Norewood).—Throw the top spit of the whole ground on one side; pare and burn the next 9 inches; spread the ashes over the whole surface, return the top spit, and fork the whole together. Bricklayers' lime rubbish will be a good manure for such a soil.

PAINT FOR HOT-WATER PIPES (K. W. G.).—Mix lampblack to the consistency of thick paint with boiled linseed oil; with this paint the pipes after they have been made as hot as possible, and keep them hot until the paint be dry. The main point is to brush the paint well in, for unless this be done effectually the composition and its application are useless. If you do not care about appearance, use red lead, which will last much longer, and so will white lead. Two coats of paint will be sufficient, but one good coat well brushed in is worth a dozen imperfect ones.

GERANIUMS DAMPING (T. A. Southwood).—The leaves show that your house is very damp. We fear that you give the plants too much water at the root, and are not careful to keep the house dry. Give no more water at the root now than is sufficient to keep the leaves from flagging. Light a fire occasionally during damp weather to promote a circulation of air and to dry up the damp, and give abundance of air on all favourable occasions. The house being cold and damp is, we think, the cause of the leaves being in the condition of those sent. Keep the atmosphere drier, and they will improve as the days lengthen.

FOUNTAIN IN FERN CASE (J. J. Romsey).—It will not make the air of the case too damp. Ventilation can always regulate the dampness.

ESPERIERE VINE (Penally).—"UPWARDS AND ONWARDS" informs us, that a parcel directed to "A. B., Penally Station, &c." To be called for," will be sent from Woodstock, on the 9th inst.

FERNS SCORCHED (E. M. H.).—Your only plan will be to keep the Ferns moderately watered, and to cut away the brown fronds as they show themselves, otherwise treating the plants as if nothing had happened. Do not give them any additional heat, as that would induce a temporary increase of growth; and as for applying manure to the roots, neither now nor at any other time will it do them any good, but, on the contrary, it will kill many. Do not overwater, but keep rather dry at the roots, sprinkle the paths in the morning of bright days, and give air during mild weather, cutting away the browned fronds before they become mouldy, and all the plants will recover if they have sufficient vitality left, but they will look bare for a long time.

OWNERSHIP IN FALLEN TREE.—W. H. W. asks—"In the event of a tree falling in an orchard through wind or any other cause, is the tree the property of the landlord or the tenant?" It belongs to the landlord. The gate of the orchard would not belong to the tenant because blown down, why should the tree?

PRIMULA SINENSIS (E. C.).—Do not pick off the trusses. Give the plants a little weak liquid manure.

LYCHNIS SENNO.—W. S., we are informed, can obtain a supply from Mr. W. Dillistone, Nurseryman, Sible Hedingham, Essex.

PRICE OF GRAPES (E. H. P.).—Last year the average price of Black Hamburg Grapes in Covent Garden Market was from 7s. to 15s. per lb., in February and March; from 15s. to 27s. in April; and from 8s. to 14s. in May. Muscats brought from 8s. to 14s. per lb. in February, after which time they were over. In considering what month is the most profitable to bring in a crop, you must not only take into consideration the probable price per lb. which the Grapes will realise at different times, but also the relative cost of the fuel required for early and late forcing, and the comparative weight of produce. *New* Black Hamburgs command a high price in spring, but the demand is limited.

PINE-APPLE-HOUSE (E. R. S.).—For thirty-two postage stamps you can have free by post from our office, "The Pine-Apple Manual." It contains drawings, &c., showing what you require.

FRUITING VINES IN POTS (W. C. W.).—Your Vines being in 12 and 13-inch pots you may fruit them in these, or you may pot them into 18-inch pots, providing good drainage, and not disturbing the roots. If you keep them in the 12-inch pots be content with putting the drainage right, relying on top-dressings of manure and applications of liquid manure at the same time. The Vines would carry a heavier crop were the pots placed on shallow tubs containing soil into which the roots could run after passing through the holes in the bottoms of the pots, which they would do freely. The canes should be cut-in, 6 feet is long enough, and always leave sufficient good plump eyes for a crop, and you will have them in that length or not at all.

GARDENER ILL-TREATED (One in Trouble).—If your account is a correct one, then we have no hesitation in saying that you have been a very valuable and faithful servant, and that you have been anything but handsomely treated in return. A man who entered into a place in April, all like a wilderness, and who managed to get the kitchen garden dug and cropped; the shrubbery and lawn put to rights; increased by propagating and begging cuttings, &c., the plants for bedding from three dozen to 1500; attended to horse and trap; was out every day from 8.30 A.M. to 8.30 P.M.; looked after milk; fed the cow, pigs, rabbits, and fowls; cleaned knives, boots, windows, went on errands, &c., and had only the assistance of a boy to help with the mowing-machine, and has now, besides making alterations, got the kitchen garden and shrubberies dug, Sea-kale and Rhubarb covered, fruit trees and bushes pruned and dressed;—must either have had a small place to look after, or it must be quite true that you have worked hard pretty well all the time from early in the morning until late at night. After all this you have been anything but well treated in receiving notice to leave from your master, because you gave a few sprigs of a Spindle Tree that stood near the stables to a neighbouring gardener for Christmas decoration, that gardener having been very kind in giving you cuttings, &c. The conduct of your employer would be still more indecipherable if he knew that you received cuttings from others and said nothing against it, as that was something like a silent understanding that you were to do the same. Nevertheless, we must own, that your employer was quite correct in stating that you had no right, in the abstract, to give away the smallest thing without his leave. If you read our previous volumes carefully, you would see that we have frequently urged in such matters the importance of gardeners never depending on use and wont, or general custom, but to have a clear understanding with their employers; and then, of course, if they are not allowed to give away a sprig, or a cutting, whatever may be the feelings of the employer, we trust there will be honest pride and self-respect enough in the gardener never to receive a cutting from others. In such cases it is the best plan to allow an employer to purchase every fresh thing he has. The neighbouring gardeners will not respect a man any the less when they know that he cannot give, and therefore will not take. The copies of your previous testimonials are quite satisfactory, and we feel certain that you will soon be in place again, and where, we trust, your services will be better appreciated; but to secure yourself from all such unpleasantness as the present, we advise you to make sure of the give-and-take principle.

NAMES OF FRUIT (J. F.).—1, Blenheim Pippin; 3, Forge; 4, London Pippin; 5, Golden Reinette; 6, Secklet Nonpareil. (J. H. C.).—1, Josephine de Malines; 3, Beurre de Ruze; 4, Vicar of Winkfield; 5, Triomphe de Jodoigne; 6, Beurre Diel; 7, Ne Plus Meuris; 8, Chantrellet; 9, Wyken Pippin; 10, Winter Quoining; 11, Franklin's Golden Pippin; 12, Duck's Bill.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending January 6th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY, PAST AND FUTURE.

We are a week behind with our good wishes to all, but they are not the less hearty. We have arrived at the period when, thankful that we have been spared in health and strength, we pass the last year in review, and scan the hopes, wishes, and prospects of the present. We are grateful to all who assist at the result, when we say the task is neither gloomy nor painful. We have had a successful year. Our circulation goes on increasing, and we have to thank the public for support in every way.

Poultry not only holds its own, but it gains in public estimation. The place that belongs to it naturally is being filled. The desire for competition does not slacken, while its importance, as it bears on the question of food, is being every day recognised. This has been the result of exhibitions, and the

consequent testing of breeds, with a view to their capability either of producing eggs or providing food. Already production is greatly stimulated, and the supply increases; but much remains to learn. We still deal with poultry as with a luxury, and those who have some to spare for the market keep it for a great event like Christmas, often to the detriment of quality, and generally to a loss. Believing we are in a transition state, we point out these things lest beginners should be discouraged. We hope if we have to record the progress of poultry during the new year, we shall have to speak of a regular supply, and not of that spasmodic sending which makes a naked market this week, to be remedied by a glutted one next. The true economy of poultry keeping, and the real profit, will be soon found to be the immediate disposal of a bird as soon as it ceases to make a good return. This will be as soon as one intended for the market is sufficiently fat, and one kept for a breeder ceases to lay a number of eggs that will be more than the equivalent of the food consumed. A poultry yard should be like a beleaguered town, and the first act of the commander

should be to get rid of all unprofitable mouths. We will leave this part of our subject, and should not have gone so much at length into it, had it not seemed to us that we were preparing a sort of favourable report for next year. We have a great satisfaction both in retrospect and anticipation. We believe we are chatting with friends. For many years we have exchanged our good wishes with "all whom they may concern." We have no fond or hard, no latent ill will to gratify; and we believe if there were any sign or shibboleth by which those connected with "The Journal" could recognise each other, the contact would be preceded by an open countenance and a hearty shake of the hand. We are speaking only of our belief; our deserts must of necessity be meted by others, but we are so sure of our motives that we would not hesitate to leave judgment in the hands of those who differ from us. Enough of ourselves.

Dorkings have advanced during the last twelve months, not so much in separate pens as in the breed taken collectively. The awards of prizes show it is a wise discretion that mingles colour. Silver-Greys took prizes, competing against all comers. Competition should seek to raise all to the highest, and not to satisfy halting ambition by lower reward. White Dorkings increase very much in size and quality. We cannot note improvement in Spanish. We believe the amateurs of this beautiful breed will have again to get the foreign birds for the sake of fresh blood, and to breed out afterwards the points in which they are inferior to ours. Cochins are still rising in popularity, and are good, but they require careful breeding. Drooping combs and vulture hocks have disfigured, and, it may be, disqualified, many an otherwise goodly pen. We are glad to see our *protégés*, the Brahmans, keeping on. We do not hesitate to say that they are destined to form a very large class, and they deserve all the honours they receive. Malays are still good, but it seems to be their province to be always in the position of the aborigines of an antipodean colony after the advent of the white man—they retain their characteristics, but their numbers decrease. The Crève Cœur class is already a success, and the breed is becoming popular. Black Hamburgs are increasing; but sufficient care is not taken to conceal their origin or their helpers. The white face shows too often. It reminds us of the helps that forty demands when it would appear twenty. Golden and Silver-pencilled Hamburgs have been beautiful as ever, and, we doubt not, have been as free layers. We can speak in unqualified praise of the Spangh; the Golden being almost perfect, the Silver very beautiful. The next class is one of our difficulties. What means can be adopted to increase the entries in the Poland classes? The quality of the birds shown is excellent, but the numbers are small—too small. The Distinct Varieties have flourished, and another French breed has made good its claims—"The La Flèche," facetiously called "The French Dorking;" an excellent fowl, we know, but we must draw a line somewhere. Just fancy anything as good as "our Dorking"—the fowl of fowls: capital breeder, no wet nurse required, and the best of food. The Game, as usual, are perfect. They cannot improve. We must believe the amateurs of this breed are imbued with its propensities, and must ask for a division of classes—one to be judged on its merits as a fighting community; the other would feed on a milk diet destroy their "horrible propensities," and have them judged as capable of fighting, but detesting the very idea of such barbarity. Failing such division, the exhibitors will be in the position of those who, when we were at school, viewed the chameleon, only they will eat each other, and not the birds. Bantams have held their own. Game, Blacks and Whites, have far outnumbered the Schrights. The latter have failed nothing in beauty, but the Silvers are getting Golden. The weights of Geese and Ducks have spread all over the land, and told their story. They may be vulgar, but they are right English food; and called on to plead as to having harboured a wish for Duck and early peas, or Goose, apple sauce, and French beans, we should have no resource but to plead guilty, and to throw ourselves on the mercy of the court. And the Turkeys—twenty pounds of good meat! When we look at them we fancy the white, succulent, flat side cut off the breast (no one who can carve a Turkey cuts from point of breast to crop), bounded by the green stuffing, and relieved by the slice of cherry ham, and we think well of those who increase such meat. May their shadows never be less.

We have reached the end of our tether. Every subject is exhausted, except that of our good wishes for all. It is said, That which is disagreeable is put off to the last, but we believe

that which is pleasant is also deferred. Is it that anticipation is before reality? We believe not. The man who feels what he is about to say is seldom eloquent. "Abuse me," said a first-rate speaker to an audience, "and I don't care a snap of the finger for you all; use me kindly, as you have done, and I am dumb." So we.

Friends, Contributors, Subscribers, we bid you God speed for the new year. We thank you for the past. We hope for the future. We wish you every good; we wish you happiness and prosperity; and that, without distinction of any kind, 1866 may be—

A HAPPY NEW YEAR.

FIRST NATIONAL SHOW OF THE POULTRY CLUB.

This, which is to be held at Rochdale on the 2nd, 3rd, and 5th of February next, promises to be very successful. Why Rochdale was selected we do not know; but even if less accessible than might be desired, the prizes are sufficiently liberal, and the entrance fees sufficiently moderate to secure a large number of exhibitors, and, we hope, a numerous attendance. There are no less than fourteen silver cups, and the prizes vary in each class from £5 for the first, to 10s. for the last. Entries close January 20th.

FIRST IMPRESSIONS OF BINGLEY HALL.

"First impressions are everything." This is one of the canons of ladies' criticism. The fair sex believe in it thoroughly, but especially in regard to themselves. Thus, for example: A lady, a good wife, and a good house-keeper into the bargain—(Will our modern fast young ladies make the last-named?) I doubt it—was anxious to receive a guest with all honour, and to make a good first impression upon him, particularly as to the appointments and finish of her house, for her husband had frequently told her that this gentleman's home was perfect in every fitting up, and that the furniture was faultless in its arrangement. Her anxiety, then, what good wife can doubt? Just before dressing for dinner she had been very busy, and time had flown. She thought, faster than usual. She glanced round her drawing-room. Was it quite in order? Were the anti-macassars all right?—the covers off all the chairs, and that ottoman glorious with worsted work? Yes, the cover was off that. The whole looked perfect—nothing stiff and formal, but all in a negligent-elegant yet orderly way, just as only an English gentleman's room can look when he has a good wife, when he! looking upwards the lady espied some dust on the chandelier. Quick as thought she mounts the table, and begins to remove the obnoxious palatable powder; when oh! alas! horrible to relate, that dreaded guest was announced—a terrible, over-punctual man, fond of quoting Lord Nelson's half-an-hour-before-time story. To be caught standing on a round table dusting a chandelier! worse, to have to make the humiliating decent duster in hand, and thus welcome the gentleman! "To make such a first impression," instead of advancing from her chair by the fire, (extending an all-graceful jewelled hand, with the daintiest of pocket-handkerchiefs in the other) was too bad, it spoilt the whole evening; and when she entered half an hour afterwards all right for the party she felt embarrassed, troubled, awkward. "What a first impression to have made!"

"First impressions are everything." How many of us married men must with a shrug own the truth of this ladies' canon.

"First impressions are everything," reads aloud to her husband one of our married lady admirers. He has been grumpy, but hearing these words he looks up, and she is gazing at him with that first-impression look of hers. "'WHA-SMIA RECTOR' is right there, my pet," he says as he turns, grumpy now no longer, a kind smile on the reader. "First impressions are everything." "Tell me not that, I knew it too well before!" raves some love-sick youth. "I saw her—I see her still—standing on the doorstep of her father's house. She was going out to play croquet. Her parasol hung on her right-hand little finger. She was buttoning her left-hand glove, and glancing down with her eyelashes—happy eyelashes!—kissing her fair cheeks. Ah! she knew I was looking at her! Oh, it was maddening!" Poor simpleton! She knew nothing of the kind; she was only looking down on her glove and thinking,

"I must really get a new pair, for these are nearly worn out." "First impressions are everything." Well, we must all own they are a great deal. You may try to reason yourself out of it, but you cannot.

Now, I was determined to let nothing spoil my first impressions of Bingley Hall. I begged friends not to tell me anything about the place. Had I heard it mentioned in the train I intended to have instantly closed my ears with my forefingers, unheeding what a peculiar first impression I should be making upon my fellow passengers. I wished my mind to be a sheet of blank paper on the subject. Should Bingley Hall prove to be a grand feudal structure of the date of Richard the First, built by Alfred de Bingley, well, be it so, but do not tell me beforehand. Should it prove to be a brick building, time of Victoria, all well and good; but do please let me get a fair unbiassed first impression of it, that is all I want.

The weather is as fine for the Birmingham Show as can be expected at this time of the year. If in December you have it dry abovehead and not frightfully cold, be thankful; as to dirt beneath, thick boots on and you are all right. Bristol station reached, and on by the Midland Railway. Clear of Bristol smoke at last. On by Berkeley Road—would that I could see Berkeley Castle, but I cannot, nor yet can I catch one glimpse of the Severn. Gloucester! well, there is the Cathedral—"pretty church that for the country," as the Cockney said (fact, I assure you), when he first saw Canterbury Cathedral. I am travelling on right comfortably with a poultry enthusiast by my side, a clergyman of course; a bright young girl, his sister, just smitten with the love of fowls and Pigeons, opposite to him, while my *vis-à-vis* is one of the outer world as to poultry. He feigns to scorn "cocks and hens," and only goes to Birmingham to see the cattle and the dogs. I am not hopeless of him; I think he is but half an opponent, and I have a good hope that the taste shown in his beautiful garden will shortly extend to his poultry yard, and "those wretched mongrels" will be dispatched in a few months. Four friends in a railway carriage, merrily chatting, berugged and great-coated, with a poultry show at the end of the journey—nay, the poultry show, and who would not be happy? Cheltenham station, but I see little of the town; of Tewkesbury nothing. Worcester, with its great bishop—a favourite, and no wonder, with the late Prince Consort—is soon passed; then on to the Black Country, and soon near to Birmingham. Red brick houses, smoky atmosphere, wet, black, narrow streets. On further, creeping on, and things begin to improve. I noticed that at the stations, especially from Gloucester onwards, I began to see eager agricultural faces waiting for the train—faces saying plainly, "We are going to the Cattle Show." I saw others not wholly agricultural, and yet eager, whom I knew I should meet (I did), in the Poultry Show, catalogue in hand. Of Bingley Hall I heard nothing, happily. An innocent voice did ask indeed, "Is it a large Show?" and was answered, "Large! I should think so! A hundred and fifty pens of Game Bantams, besides the Black, White, and Yellow, to say nothing of the larger fowls." Then my friend at my left was an exhibitor at Bingley Hall. His thoughts were evidently there. How he longed to see his pens, and yet the sublime indifference he assumed! But in spite of it, how his conversation turned again, and again, and again—and no wonder—upon his prospects! Now his spirits sank to zero—"They'll not be noticed!" Anon they rose, turning to me with "Don't you think that Dorking cock will do something?" Then at intervals, "Those stupid Judges! I believe they only guess after all; they really know nothing about it." I do not think I dare become an exhibitor, it must be so wearing to the nervous system. I would advise all life assurance companies to add to their terrific questions this one, "Are you an exhibitor of poultry?" with an N.B., "If you are, we cannot insure your life."

At Birmingham at last, as that explosion in the proof-house tells us—Birmingham, the land of guns and gunmakers. And what a station this one in New Street is! surely larger than the one at Paddington. Soon, passing some beautiful specimens of modern street architecture, I turn to the left, and am one of a stream of people on their way to Bingley Hall. Presently I pass the famed Town Hall; surely 'tis some beautiful temple transplanted from Greece. As I trudge my not weary way I remember that the Birmingham Show is fondly called "The Mother of Shows." Here the experiment of bringing poultry together for exhibition and competition was first tried in 1847, and here a show has been held each year since. Birmingham is undoubtedly well situated for the purpose—in the heart of England, accessible from all sides, far

enough north, and yet not too far, with an enterprising population, many of them devoted from time immemorial to birds. A first-prize at Birmingham is the ambition of many a poultry fancier. "I don't care for little shows, I want to win at Birmingham, I shall not be satisfied until I do:" this is the feeling. Then other Committees feel, "What do the Birmingham Committee do? What do they say?" Thus musing I walk on; but a placard catches my eye, "To the Dog Show," and to the left I see a new building called "Curzon Hall," which has become for the time "a howling wilderness." Further, then a turn to the right, and I am brought to a standstill, where carriages, and cabs, and foot-passengers are jostled together, and on the curbstones of the opposite pavement the ticketless stand gazing and longing to enter. Passive in the hands of a black-helmeted policeman (I wonder if Millais could have brought tears to our eyes if instead of a Black Brumswicker he had painted a policeman), I am guided to a green-baize screen, and pass, sorely jammed, through a turnstile, and I am in—Bingley Hall.

In front of me is a large hollow square, with a narrow gallery above, and in the said square fat bees, and cows, and sheep, and pigs, some of the creatures marvelously fat; there are also agricultural implements to the left. I often wonder when I see a number of people feeling fat cattle how many are the wiser for so doing; but it looks farmer-like and learned, so it is done. But a shrill crowing (I had not yet heard the howling and yelping of the dogs), guides my feet to the left; when, descending a few steps, I enter a side hall not galleried, and occupied, large as it is, by nothing but—poultry: number of entries, 1675! Think of that! I wander round perfectly bewildered. I am free to confess that my first impression was—confusion. I was confused, and permitted myself to be. Round and round I went, then through the cross paths (so to speak). My only hope the first day was to become used to the scene, and on the next, having learned something of localities, to examine the different varieties of poultry at my leisure. I was like a boy in London for the first time, he wonders and is bewildered, then presently he begins to know squares and streets.

I ascend (after hours of wandering and wondering, feeling that chaos had come back to earth, and that its inhabitants, to make it more chaotic, were crowing cocks), the narrow gallery before mentioned partly around the cattle hall, and find the Pigeons; a pleasant change this gentle and but occasional cooing for ear-piercing crowing. Opposite to the Pigeons in the gallery lay wondrous roots, and I am entreated to examine them; but in close proximity to beautiful birds I felt a rooted objection to them, and would not notice them. I spend hours in the Show, among the fowls or in front of the Pigeons, gradually becoming used to the scene, and yet my principal feeling was amazement! Four o'clock comes, and with that hour a tremendous crowd. I had kept myself tolerably perpendicular till then, occasionally spun round by some preposterous erinoline, feeling as a top must feel the moment after the string round it has been drawn suddenly away. But now the crowd becomes crushing—almost dangerous. Darkness was coming on when, getting more bewildered as the crowd increased, I had the happiness to be recognised by my future host, and carried off clear of Birmingham smoke and crowds to his charming residence and hospitable hearth. Such of Monday, my first day in Bingley Hall.—WILTSHIRE RECTOR.

(To be continued.)

PHILOPERISTERON SOCIETY.

THIS Society, formed in 1847 for the improvement of every variety of Pigeon, held its nineteenth anniversary at the Freemasons' Tavern on Thursday last. The attendance of visitors was not quite so numerous as on many former occasions; nevertheless, a vast number were admitted by tickets to the great hall of the Freemasons' Tavern, in which the Exhibition was held. Those who had not previously witnessed this interesting collection must have been highly gratified at the sight of such a number of Pigeons of almost every variety known to the fancier.

A splendid collection of Carriers was exhibited by Messrs. Square, Dale, Hedley, and Everitt. A Black cock, the property of the first-named gentleman, elicited much admiration—in fact, a finer specimen is seldom seen, the wattle being perfection. A Dun hen, the property of Mr. Dale, was also much admired.

Mr. Wicking as usual showed some superb specimens of Magpies, Turbits, Fantails, Jacobins, &c., all in most beautiful condition and health.

Almonds were better represented on this occasion than they have

been for some years past, Mr. Lucy and Mr. Merck bearing the palm.

Mr. Percivall exhibited a pen of splendid Dragons, some of which have taken prizes in all parts of the country; also some Short-faced Baldheads, Mottles, &c. Mr. Esquimaux's Yellow Tamblers were much admired, being particularly fine in colour.

We regret that this Exhibition, which has always been so largely contributed to by a splendid collection of Powters, should on this occasion have been entirely without that much-admired variety. On the whole, however, both members and visitors must have felt much pleased with the day's proceedings.

PAISLEY ORNITHOLOGICAL ASSOCIATION SHOW.

This annual Exhibition took place on the 1st inst. in the new Volunteer Drill Hall. Every year the collection of birds seems better than in the previous one, but on this occasion it greatly excelled in quality and variety any Show which the Association has held. Upwards of 1200 birds were exhibited, and an unusually large number of sales were effected. The accommodation in the new hall was also excellently suited for the Show, and though the weather was disagreeable, the visitors poured into the Exhibition from the opening till the close.

We append a list of the prizes:—

SPANISH.—First, J. Henderson, Carfin Mill, Motherwell. Second W. Creelman, Kilmarnock. Third, A. Paterson, Airdrie. Chickens.—First, J. Ridpath, Edinburgh. Second, A. Harvey, Stewarton. Third, T. Knowles, Aberdeen. Silver Cup, A. Yuil, Airdrie.

DOCKINGS (Coloured).—First, W. Reid, Hayston, Kirkintilloch. Second, H. Heys, Springfield House. Third, J. Elsworth, Campsie Junction. Chickens.—First, Third, and Silver Cup, R. Campbell, Cardross. Second, R. Logan, Netherton.

DOCKINGS (White).—First, T. Wallace, Roseland Cottage, Troon. Second and Third, J. Aitken, Paisley.

CHINESE.—First, H. Price, Glasgow. Second and Third, J. Stuart, Thistlebank, Helensburgh.

BRAMA POOTRAS.—First, J. Stuart. Second, R. Abercrombie, Paisley. Third, J. Bell, Overcrown House, Partick.

OLD SCOTCH BREED.—First and Medal, C. McDairmid, Market Street, Glasgow. Second and Third, J. Paul, Govan Street, Glasgow.

HAMBURGS (Golden-spangled).—First, H. Currie, Ardrossan. Second, and Cup, R. Cunningham, Stewarton. Third, J. McAdam, Rosebank Cottage, Bally.

HAMBURGS (Golden-pencilled).—First and Cup, J. Urquhar, Ballat Cottage. Second, R. Murray, Paisley. Third, J. Paton, Stewarton. Highly Commended, J. Urquhar.

HAMBURGS (Silver-spangled).—First, J. Stewart, South Arthurlie, Barhead. Second, S. C. Noble, Kendal. Third, A. Glen, Erskine.

HAMBURGS (Silver-pencilled).—First and Second, J. Paton. Third, J. Crookston, Bishopbriggs.

POLANDS (White-crested).—First and Second, J. Paul.

POLANDS (Any other colour).—First, W. R. Park, Melrose. Second, W. Ramsay, Johnstone. Third, A. Jardine, Cardonald.

GAME (Black-breasted, and others).—First, J. McNab, South Arthurlie, Barhead. Second and Cup, W. Easton, Abbey Place, Jedburgh. Third, J. Anderson, Ruthven House, Meigle. Highly Commended, A. Gibb, Ayr.

GAME FOWLS (Any other colour).—First, A. McCulloch, Trees, Barhead. Second, J. Anderson. Third, W. Easton.

GAME BANTAMS (Any colour).—First and Medal, J. Ecll. Second, J. Sharp, Johnstone. Third, A. Campbell, Blythwood.

BANTAMS (Black).—First, A. Jamieson, Kilmirnie. Second, A. Sym, Kilmarnock. Third, W. Lockhart, Kilmarnock.

BANTAMS (Any other kind).—First, W. Raeside, Irvine. Second, W. Morris, Paisley. Third, D. Murray, Edginton Castle.

CROSS OR ANY OTHER BREED.—First, W. White, Paisley. Second, A. Campbell. Third, J. Fulton, Beith.

DUCKS (Aylesbury).—First, A. Cunningham, Craigends. Second, I. Campbell. Third, J. Crookston. Highly Commended, W. McKeggie, Bowfield, Howwood. Commended, H. Heys.

DUCK (Any other kind).—First, A. Campbell. Second, Mrs. A. Arthur, Cumnock. Third, J. Crookston.

PIGEONS.—First, R. Fulton, Duke Street, London. Second, G. White, sen., Paisley. Third and Medal, R. Fulton.

CARRIERS.—First, G. White, sen. Second, R. Fulton. Third, G. White, jun., Paisley.

FANTAILS.—First and Medal, J. Sharp. Second, W. R. Park. Third, J. R. Remnads, Helensburgh.

RUFFS.—First, J. Sharp. Second, A. Middleton, Monmouthshire. Third, R. Barclay, Canal Bank.

SHORT-PALED TUMBLERS.—First, R. Fulton. Second, G. White, sen. Third, D. Raeside, Saltcoats.

TUMBLERS (Any other kind).—First, W. R. Menzies, Crossmyloch. Second and Third, J. Sharp.

ANY OTHER DISTINCT BREED.—First, J. Prentice, Glasgow. Second, J. R. Remnads. Third, J. Sharp.

COMMON PIGEONS.—First, J. Glasgow, Dalry. Second, W. Menzies, Kilmirnie. Third, J. Neilson, Johnstone.

CANARIES.

PAIR FOR SILVER MEDAL.—W. Houston, Paisley.

YELLOW COCK.—First, W. M'Leod, Glasgow. Second, G. Ayton, Glasgow. Third, R. Wood, Paisley. Fourth, T. Buchanan, Glasgow.

BUFF COCK.—First, J. Graham, Kilmarnock. Second, A. Kelly, Paisley. Third, J. Richmond, Kilmarnock. Fourth, G. McAlpine, Renfrew.

YELLOW HENS.—First, R. Paterson, Glasgow. Second, J. Graham, Kilmarnock. Third, A. Kelly, Fourth, J. Wilson, Galston.

BUFF HENS.—First and Silver Cup, W. Soudan, Paisley. Second, J. Graham. Third, J. Kelly, Johnstone. Fourth, C. McWilliams, Glasgow.

PAIR PEBALD CANARIES FOR CAGE.—G. McAlpine.

PEBALD YELLOW COCK.—First, T. Buchanan. Second, A. Kelly. Third and Fourth, G. Haddow, Kilwinning.

PEBALD BUFF COCK.—First, J. Mathews, Glasgow. Second, A. Crawford, Johnstone. Third, R. Wylie, Paisley. Fourth, W. M'Leod, Glasgow.

PEBALD YELLOW HENS.—First, R. Calderwood, Kilmarnock. Second, J. Wilson, Galston. Third, W. Robertson, Paisley. Fourth, W. Paterson, Glasgow.

PEBALD BUFF HENS.—First, J. Mathews. Second, J. Richmond. Third, R. Wood. Fourth, T. Buchanan.

YELLOW GOLDFISCH MULL.—First, W. R. Menzies. Second, W. Fleming, Glasgow.

PURE GOLDFISCH MULL.—First, J. B. Adam, Ayr. Second, J. Graham, Goldfishon. First, G. Haddow, Kilwinning. Second, A. Adam, Paisley.

PURE FISCH.—Prize, A. Cunningham.

HONORIFIC PRIZES.—First, J. Agnew, Paisley. Second, G. B. Armour, Paisley.

JUDGES.—For Poultry: Mr. J. Crawford, St. Rollox, Glasgow; J. Steven, M.D., Arhossan; Mr. E. E. C. Benton, Jarnie House; Mr. W. Farquhar, Barhead; D. Dugald, M.D., Strathvan; Mr. J. Holburn, Stewarton; Mr. H. Todd, Paisley. For Pigeons: Mr. G. J. McLean, Edinburgh; Mr. J. Paton, Stewarton. For Small Birds: Mr. G. Grant, Paisley; Mr. W. White, Renfrew; Mr. D. Buchanan, Paisley; Mr. M. Wilson, Paisley; Mr. T. Buchanan, Glasgow; Mr. J. Wren, Pollokshaw; Mr. A. Brown, Swarden; Mr. W. Taylor, Glasgow.—(North British Daily Mail.)

ABERDEEN POULTRY SHOW.

The fifth annual meeting of the Aberdeenshire Association for the improvement of Poultry, Pigeons, and Canaries, was held in the Artillery Gymnasium, Queen Street, Aberdeen, on Monday and Tuesday, the 1st and 2nd inst. The following is the list of awards:—

SPANISH.—First and Cup, Miss B. Bidpath, Edinburgh. Second, E. Draper, Northampton. Third, G. Wallace, Aberdeen. Highly Commended, A. Cochran, Perth. Commended, Mrs. M. U. B. Cross, Monifeth, near Dundee; T. Knowles, jun., Aberdeen. Chickens.—First and Cup, S. Mitchell, Aberdeen. Second, W. Meff, Aberdeen. Third, J. H. Wilson, St. Bees, Cumberland. Highly Commended, W. Meff. Commended, T. Knowles, jun.

DOCKINGS (Silver-Grey).—First and Cup, J. Gordon, Manar, Aberdeen. Second, Hon. Mrs. Arluthnott, Inchmarine, Inchture. Third, J. E. Wilson. Highly Commended, T. Knowles, jun. Chickens.—First, J. Curror, Comiston, near Edinburgh. Second, D. King, Aberdeen. Third, A. F. Williamson, Blackburn. Highly Commended, A. Copland, Kintore; T. Knowles, jun.

DOCKINGS (Any other variety).—Cup, First, and Second, Hon. Mrs. Arluthnott (Silver-Grey). Third, J. Anderson, Meigle (Dark Grey). Highly Commended, T. Knowles, jun. Commended, Miss Black, Banchoy Terman; J. Anderson, Dark Grey. Chickens.—First and Second, J. Anderson (Dark Grey). Third, J. K. Fowler, Aylesherry. Highly Commended, Mrs. M. U. B. Cross; Hon. Mrs. Arluthnott (Dark Grey). Commended, Mrs. M. U. B. Cross; T. Knowles, jun. (Dark Grey).

COCHIN-CHINA (Buff and Cinnamon).—First and Cup, W. Hendry, Aberdeen. Second, T. Knowles, jun. Third, Messrs. Bown & Greenwood, Harrogate. Chickens.—First, J. Poole, Ulverston, Lancashire. Second, T. Knowles, jun. Third, Messrs. Bown & Greenwood. Highly Commended, Mrs. Tocher, Aberdeen; G. Murray, Aberdeen; C. Pease, Southend, Darlington. Commended, Miss E. A. Aglionby, Grassmere; W. Hendry, Aberdeen; Hon. Mrs. Arluthnott; T. Knowles, jun.

COCHIN-CHINA (Any other variety).—First and Cup, E. Tudman, Ayle Grove, Whitechurch, Salop (Partridge). Second, H. Yardley, Birmingham. Third, J. K. Fowler (Partridge). Chickens.—First, E. Tudman (Partridge). Second, J. Poole, Ulverston, Lancashire (Grouse or Partridge).

BRAMA POOTRAS.—First and Cup, R. W. Boyle, Bray, Co. Wicklow, Ireland. Second, H. Lacy, Hebbin Bridge, Yorkshire. Third, C. Pease. Highly Commended, Hon. Mrs. Arluthnott. Chickens.—First, R. W. Boyle. Second, J. K. Fowler. Third, Mrs. Carnegie, Rediall, Penrith. Highly Commended, R. O. Farquharson, Hanton; T. Knowles, jun. Commended, J. Clark, Fochabers Station; Mrs. M. U. B. Cross; Hon. Mrs. Arluthnott.

GAME (Red).—First, J. Anderson. Second, W. Hay, Aberdeen. Third, Mrs. M. U. B. Cross. Highly Commended, Mrs. Reniet, Aberdeen. Commended, J. Wood, Wigan, Lancaster. Chickens.—First and Second, J. Anderson. Third, J. Wood. Very Highly Commended, J. H. Macnab, South Arthurlie, Barhead. Highly Commended, J. Wood; A. Stapleton, Premnay, by Insh.

GAME (Any other variety).—First, S. Matthew, Stowmarket, Suffolk (Duckwing). Third, F. J. Boy, Younger of Southorn, Kelso (Duckwings). Third, J. Anderson (Duckwings). Commended, J. Anderson (Duckwings).

HAMBURGH (Golden-pencilled).—First, Mrs. Macnab, Midbelle, Kincardine O'Neil. Second and Third, J. Riach, Aboyne.

HAMBURGH (Golden-spangled).—First, A. Copland. Second and Third, Mrs. Stronach, Aberdeen. Commended, A. Copland.

HAMBURGH (Silver-spangled).—First, M. U. B. Cross. Second and Third, Mrs. Stronach.

POLANDS (Any variety).—First, W. Silvester, Hempden View, Sheffield (Gold). Second and Third, Comtess de Flahault, Tullyallan Castle, Kincardine-on-Forth (Buff and Silver).

ANY OTHER VARIETY.—First and Second, Hon. Mrs. Arluthnott (Crève Coeur and La Fleche). Third, Comtess de Flahault (Crève Coeur). Commended, Hon. Mrs. Arluthnott (Crève Coeur).

GAME BANTAMS.—First, Rev. G. Raynor, Kelvedon Hatch Rectory, near Brentwood, Essex. Second, J. Anderson. Third, W. F. Entwisle, Otley, Yorkshire. Very Highly Commended, Mrs. M. U. B. Cross. Highly Commended, Mrs. M. U. B. Cross. Commended, G. Spalding, Drumstadie, near Dundee.

BANTAMS (Any other variety).—First and Second, M. Leno, Markyate Street, Dunstable (Silver-faced and Gold-faced). Third, J. Ness, Lathhead, Kirkcaldy (Gold-faced). Very Highly Commended, Mrs. M. U. B. Cross.

(Silver Sebright). Highly Commended, H. E. Emberlin, Leicester (White); Mrs. M. U. B. Cross (Golden Sebright).

TURKEYS (Any variety).—First, Hon. Mrs. Arbuthnot. Second, Mrs. Carnegie. Third, J. Gordon. Highly Commended, Mrs. Stronach. Commended, Mrs. Carnegie; J. Gordon.

GESE (Any variety).—First and Second, Hon. Mrs. Arbuthnot (Toulouse). Third, J. K. Fowler (Toulouse). Commended, Mrs. Carnegie (Toulouse).

DUCKS (White Aylesbury).—First and Second, J. K. Fowler, jun. Third, A. Farquhar, Elsieck, near Stonehaven. Commended, Mrs. F. W. G. Gray, Aberdeen; J. K. Fowler.

DUCKS (Any other variety).—First, J. K. Fowler (Rouen). Second, T. C. Harrison, Hull (Brown Call). Third, J. Anderson (Rouen). Highly Commended, J. Menzies, Kincardine-on-Forth (Rouen); J. Anderson (East Indians). Commended, Mrs. Carnegie (Rouen); Mrs. F. W. G. Gray (White French); Hon. Mrs. Arbuthnot (Rouen).

SELLING CLASS (Any variety).—First, J. Anderson (Dorkings). Second Mrs. Rennett (Game). Third, H. Ashton, Manchester (Nankin Bantams) Highly Commended, W. Anderson, Cove, by Aberdeen (Spanish); R. Tate, Leeds (Game Bantams). Commended, Mrs. Black (Dorkings).

SINGLE COCKS.

SPANISH.—First, T. Knowles, jun. Second, W. Meff. Third, G. Wallace, Dorking.—First, G. Campbell, Tillinamolt, New Pittshigo. Second, Mrs. Black. Third, Comtesse de Flahault. Highly Commended, A. F. Williamson, Caskichen Mains, Blackburn; W. Forbes, Whiteford, Pitoule. Commended, Mrs. W. Pyper, Belhelvie Village.

COCHIN-CHINA.—First, T. Knowles, jun. Second, Mrs. Tocher, Aberdeen. Third, W. Massey, Fulford, York. Highly Commended, W. Hendry; G. Murray. Commended, G. Murray.

BRAMA POOTRA.—First, J. K. Fowler. Second, Hon. Mrs. Arbuthnot. Third, J. Masson. Highly Commended, P. Campbell, New Deer; T. Knowles, jun. Commended, Mrs. Stronach.

GAME.—First and Cup, J. Brough, Carlisle. Second, M. Billing, jun., Birmingham. Third, W. Gamon, Thornton-le-Moors, Chester. Very Highly Commended, F. W. G. Gray; T. Burgess, Burleydam, Whitechurch, Salop; A. B. Dyas, Madeley, Shropshire; T. Knowles, jun. Commended, W. Boyes, Beverley, Yorkshire; R. Swift, Southwell, Notts.

HAMBURGH.—First, G. Campbell. Second, Mrs. Stronach. Third, P. Campbell.

SWEETSTAKES FOR GAME COCKERELS.—First and Cup, N. Grimshaw, Brindley, Lancashire. Second, J. H. Macnab. Third, M. Billing, jun., Birmingham. Fourth, A. B. Dyas. Highly Commended, J. H. Macnab; T. Burgess; J. Anderson; F. L. Roy, jun., Nenthorn, Kelso. Commended, C. Jamieson, Forfar.

SWEETSTAKES FOR BANTAM COCKS.—First and Cup, M. Leno. Second, G. Manning. Third, J. W. Morris, Rochdale, Lancashire. Fourth, Rev. G. Raynor. Highly Commended, W. P. Entwistle; Sir G. McPherson Grant, Bart., Ballindalloch; J. Crossland, jun., Wakefield; F. L. Roy, jun. Commended, W. T. Hay, jun., Aberdeen; W. Hodgson, Darlington.

PIGEONS.

POWERS (Any colour).—First, M. Sanderson, Edinburgh. Second, J. R. Robinson, Sunderland. Very Highly Commended, J. Hay; M. Sanderson. Highly Commended, H. E. Emberlin. Commended, F. McCrae, Aberdeen. *Cock*.—First, M. Sanderson. Second, J. R. Robinson. Very Highly Commended, M. Sanderson. Highly Commended, F. McCrae; M. Sanderson; J. Thackray, York. Commended, M. Sanderson. *Hen*.—First and Medal, J. R. Robinson. Second, M. Sanderson. Highly Commended, H. E. Emberlin. Commended, E. E. M. Royds, Rochdale.

CARRIERS (Any colour).—First, T. Shefield. Second, H. Allsop, Birmingham. Highly Commended, W. Massey, York. Commended, W. Tocher, Aberdeen; H. Martin, Glasgow; T. Knowles, jun. *Cock*.—First, W. Massey. Second, T. Colley. *Hen*.—First, H. Martin. Second, W. Massey. Highly Commended, F. McCrae; T. Colley.

ALBION TUMBLERS.—First and Third, J. R. Robinson. Second, J. Thackray. Highly Commended, T. Knowles, jun. Commended, W. Tocher.

TUMBLERS (Any colour).—First, J. McDonald, Aberdeen. Second, H. Yardley. Highly Commended, T. Knowles, jun. Commended, M. Sanderson; J. R. Robinson.

FANTAILS (Any colour).—First, J. R. Robinson. Second, J. Thackray. Very Highly Commended, J. R. Robinson; J. Rae, Guestrow, Aberdeen. Highly Commended, H. Yardley; T. Knowles, jun. Commended, J. McDonald; T. Knowles, jun.

JACOBS (Any colour).—Medal, T. Knowles, jun. First and Second, J. T. Lawrence, Liverpool. Very Highly Commended, J. R. Robinson; J. T. Lawrence. Commended, J. T. Lawrence; H. Yardley.

TURBITS AND OWLS (Any colour).—First, J. Thackray. Second, H. Yardley. Very Highly Commended, H. E. Emberlin; A. Murray. Highly Commended, Mrs. M. U. B. Cross; W. Massey; J. Hay. Commended, J. R. Robinson; Mrs. M. U. B. Cross; H. Yardley.

EARS (Any colour).—First, J. Thackray. Second, W. Massey. Very Highly Commended, J. T. Lawrence. Highly Commended, J. B. Robinson.

TRUMPETERS (Any colour).—First and Second, J. R. Robinson. Very Highly Commended, E. E. M. Royds; H. Yardley.

ANY OTHER VARIETY.—Medal, First, and Second, J. Thackray (Maggies and Nuns). Very Highly Commended, J. Hay (Dragons). Highly Commended, E. E. M. Royds (Nuns); Comtesse de Flahault (Romans); H. Yardley. Commended, J. Percival, Peckham, London (Archangels).

CANARIES.

BELGIAN (Yellow).—*Cock*.—First, A. Murray. Second, A. Barnett, Aberdeen. Third, J. Mitchell. Aberdeen. Very Highly Commended, A. Murray. Highly Commended, W. Sircell, Aberdeen. *Hen*.—Very Highly Commended, J. Wishart, Aberdeen. Highly Commended, A. Murray.

BELGIAN (Buff).—*Cock*.—Very Highly Commended, J. Mitchell. *Hen*.—First, R. Baist, Aberdeen. Second, R. Smith, Inverury. Third, W. Wilson, Aberdeen. Very Highly Commended, J. Mitchell.

BELGIAN (Fleeced).—*Cock*.—First and Third, J. Falconer, Aberdeen. Second, W. Mitchell, Aberdeen. Very Highly Commended, A. Middleton. *Hen*.—First, J. Ross, Aberdeen. Second, J. Skinner, Aberdeen. Third, R. Ross, Aberdeen. Very Highly Commended, R. Baist.

SCOTCH FANCY.—First, R. Ross. Second, J. Ross. Third, W. King, Dundee. Very Highly Commended, J. Ross.

ANY OTHER VARIETY.—First, W. Aiken, Aberdeen (Common Fleeced *Cock*). Second, A. Middleton, Aberdeen (Fleeced half-Belgian *Cock*). Third, J. Mitchell (Common *Cock*).

GOLDFINCH MULE.—First, Second, Third, and Very Highly Commended, J. Hunter, Aberdeen.

BIRDS OF 1865.

BELGIAN (Yellow).—*Cock*.—First and Third, J. Mitchell. Second, W. Wilson. Very Highly Commended, R. Baist. *Hen*.—First, J. I. Garden, Aberdeen. Second, J. Wishart, Aberdeen. Third, A. Middleton. Very Highly Commended, J. I. Garden; J. Mitchell.

BELGIAN (Buff).—*Cock*.—First, A. Gemlo, Aberdeen. Second, A. Middleton. Third, A. Murray. Very Highly Commended, W. King. *Hen*.—First, J. Law, Aberdeen. Second, J. Mitchell. Third, W. Sircell.

BELGIAN (Fleeced).—*Cock*.—First, J. Ross. Second and Third, A. Murray. Very Highly Commended, J. Nicoll, Aberdeen. Highly Commended, A. Middleton. *Hen*.—Very Highly Commended, J. Ross.

DUMFRIES AND MAXWELLTOWN ORNITHOLOGICAL SOCIETY'S EXHIBITION.

THE seventh annual Exhibition of Canaries, Poultry, Pigeons, and Parrots, of the above Society was in the Mechanics' Hall, Irish Street, on the 2nd and 3rd inst. It was one of the finest shows of the kind ever held in the south of Scotland. In the number of entries, superior condition of the birds, their excellent quality, and admirable arrangement of the coops, &c., it exceeded all former competitions.

Such a display of fowls has never been witnessed in this district. Every bird was in splendid feather, and seemed a pattern of its kind, and the Judges must have had no light task in comparing the points of excellence in each, and making the awards. Of the different descriptions of *Game* fowls there was a large display, and the White and the Black specimens were beautiful birds. For *Spanish* fowls Mrs. Smith, Broomhills, stands unsurpassed, her fowls having gained the chief premiums in both classes. They were reared, we understand, from eggs furnished by Miss Smith, Braes. *Dorkings* were numerous, and the competition good; but there were few *Cochin-Chinas*. *Hamburghs*—Spangled and Pencilled, Golden and Silver, old and young—were well represented, and added greatly to the attractions of the Exhibition. Though the display of *Brahma Pootras* was not large, it included some fine birds. Mr. Miller, Bowes, Terregles, showed a pair of well-feathered Guinea-fowls. The competition among the *Bantams* was very keen, as the number shown was large, and the quality of the birds in general excellent. A better show of *Pigeons* we have never seen anywhere, and the varieties must have greatly surprised the generality of visitors, as there were no fewer than fifteen. Besides the more common breeds were Nuns, Trumpeters, Blue Brunswicks, Antwerp Carriers, Archangels, and Turtle Doves, all beautifully clean and in fine feather. There were few *Parrots* exhibited, and the only foreign birds competing were a Green Parrot, St. Helena Canary, and pair of Love Birds. The British birds shown were a Crossbill, Siskin, Redpole, Goldfinch, and *Cock* of the North. Mr. McCrie, Southern Counties' Asylum, had a fine aviary, in which was a happy family of Bullfinches, Goldfinches, Grey Linnets, Redpoles, Chaffinches, Green Linnets, Siskins, &c. The Judges' awards gave general satisfaction, but some were not satisfied, and we were sorry to see a Dumfries exhibitor so far forget himself as to break through all law and order by removing the coop containing his fowls. It was well for the success of the Exhibition that his example was not followed. The arrangements seemed to be perfect, and were highly creditable to Mr. Maxwell, Secretary, and the members of the Committee.

GAME (Black Reds, Blacks, and other Reds and Blues).—First and Silver Medal and Second, W. D. Dickson, Carron Croft. Commended, T. Maxwell, Maxwelltown. *Chickens*.—First, S. Lord, Lockerbie. Second, J. B. Lockerbie, Wallacecove. Commended, J. Stobo, Jericho.

GAME (Duckwings, Whites, and other Greys).—First, A. McKie, Maxwelltown. Second, T. Henderson, Dumfries. Commended, S. McMillan, *Chickens*.—First, T. Henderson. Second, J. B. Lockerbie. Commended, C. Turner, Dumfries.

SPANISH (Black).—First, Mrs. Smith, Broomhills. Second, J. Kerr, Broekelirst. Commended, T. Maxwell, Alhanton Mill. *Chickens*.—First and Silver Medal and Second, Mrs. Smith. Commended, R. McKenzie. *Dorkings*.—First and Silver Medal, W. F. H. Arndell, Barjang Tower. Second, Miss M. Holm, Hillhead. Commended, J. Maxwell, Dalwinstoun. *Chickens*.—First, Miss M. Holm. Second, Miss M. A. Johnstone, Terregles. Commended, J. Maxwell.

COCHIN-CHINA (Any Colour).—Prize, Miss Biggar, Braes House. *Chickens*.—First, Mrs. Moffat, Kirtle Bridge. Second, Mrs. Waugh, Castlehill, Lochmaben.

HAMBURGH (Golden-spangled).—First, T. Musgrove, Longtown. Second, W. Currie, Maxwelltown. Commended, R. Murray, Maxwelltown. *Chickens*.—First and Silver Medal, Miss Biggar. Second, T. Musgrove. Commended, R. Kerr, Barjang.

HAMBURGH (Golden-pencilled).—First, Mrs. Blacklock, Huton Park, Lockerbie. Second, T. Johnstone, Waterside, Terregles. Commended, W. Stewart, Ra-shigill. *Chickens*.—First, W. Wallace, Kirkmahoe. Second, R. Smith, Greenbrae. Commended, J. Jardine, Maxwelltown.

HAMBURGH (Silver-spangled).—First, C. Inglis, Lockerbie. Second, Mrs. Crombie, St. Michael Street, Dumfries. Commended, T. Connel, Lochaberbrigs. *Chickens*.—First, R. Jardine, Moffat. Second, W. Currie. Commended, S. Boyes, Blairshinnel.

HAMBURGH (Silver-pencilled).—First, R. Young, Lochaberbrigs. Second, Miss Johnstone, Broadholm. *Chickens*.—First and Silver Medal, T. Musgrove. Second, W. C. Stewart, Kirkebright. Commended, E. Young.

BRAMA POOTRA.—First, Mrs. Waugh. Second, Mrs. R. K. Howat, Mable. *Chickens*.—First, Mrs. Waugh. Second, Mrs. R. K. Howat. Commended, Mrs. R. K. Howat; Mrs. Waugh.

SCOTCH GRAYS.—Prize, C. Robertson, Eaglesham, Glasgow.

BANTAMS (Gold-laced).—First and Silver Medal, W. W. Anderson, Chapel, Moffat. Second, G. Smith, Dumfries. Commended, T. Wright.

BANTAMS (Black).—First, Mrs. Coupland, Dumfries. Second, J. Thomson, Maxwelltown. Commended, J. Irving, Dumfries.
BANTAMS (White).—First, J. McIlwain, Dumfries. Second, T. Maxwell, Dumfries. Commended, R. Teuton, Dumfries.
GAME BANTAMS (Black Reds and other Reds).—First, J. Douglas, Maxwelltown. Second, R. Browning, Porterstown, Keir. Commended, J. Douglas.
GAME BANTAMS (Duckwing and other Greys).—First, J. Sharp, Canal Cottage, Johnstone. Second, A. Mitchell, Hawick.
BANTAMS (any other Variety).—Prize, J. Palmer, Maxwelltown.
DUCKS (Roman).—First, J. Boyd, Southwick. Second, Miss M. J. Russell, Moffat. Commended, W. W. Anderson.

PIGEONS.

SHORT FACED TUMBLERS.—First, W. Currie. Second, R. Henderson, Maxwelltown.
COMMON TUMBLERS.—First, J. Sharp (Blue Beards). Second, R. Henderson.
CARRIERS.—First, R. Henderson. Second, J. Paterson, Dumfries.
POWERS.—First, J. Sharp. Second, J. Thomson.
JACOBIANS.—First and Second, J. Sharp.
PASTALS.—First, J. Sharp. Second, W. Greig, Elmbank.
COMMON PIGEONS.—First, W. Currie. Second, W. Howat, Dumfries.
ANY OTHER DISTINCT BREED.—First, J. Sharp (Blue Brunswick). Second, A. Mitchell (Nuns).

CANARIES.

SCOTCH FANCY (Yellow Cocks).—First and Silver Medal, J. Graham, Kilmarnock. Second, J. Thorpe, Dumfries. Third, J. Harding, Maxwelltown. *Hens.*—First, J. Thorpe. Second, J. Muir, Kilmarnock. Third, J. Graham. *Buff Cocks.*—First, J. Graham. Second, J. Muir. Third, J. Thorpe. *Hens.*—First and Third, J. Thorpe. Second, J. Little, Dumfries.
PIEBALD (Yellow Cocks).—First and Silver Medal, J. Low, Beattock, Moffat. Second, J. Thorpe. Third, R. McCubbin, Annan. *Hens.*—First and Second, J. Thorpe. Third, R. Edgar, Maxwelltown. *Buff Cocks.*—First, J. Low. Second, J. Little. Third, R. McCubbin. *Hens.*—First, J. Low. Second, J. Little. Third, R. Edgar.
GOLDFINCH MULES (Yellow).—First, J. Kirk, Dumfries. Second, J. Thorpe. Third, R. Davidson, Carlisle. *Buff.*—First and Third, R. Davidson. Second, W. Fleming, Holywood.
GOLDFINCHES.—First, J. Wilson, Dumfries. Second, J. Thorpe, Third, D. Coupland, Maxwelltown.

PARROT (Any colour).—Prize, Miss Brown, Dumfries.
FOREIGN BIRD (Any other variety).—Prize, J. Armstrong (Love Bird).
RAREST BRITISH BIRD (Any variety).—Prize, J. McCrie (Pair of Cocks of the North).

JUDGES.—For *Canaries and Parrots*: Mr. T. Hadow, Glasgow, and Mr. G. Crawford, Beith. *Poultry and Pigeons*: Mr. J. Paton, Stewarton, and Mr. R. Bailey, Carlisle.—(*Dumfries and Galloway Standard*).

KIRKCALDY POULTRY SHOW.

The annual Exhibition of the Fife and Kinross Ornithologica Society, was held in the Corn Exchange, Kirkcaldy, on Monday and Tuesday, the 1st and 2nd inst., when the following prizes were awarded:—

DORRINGS (Chickens).—First and Third, J. Spalding, Leslie. Second, J. Stock, West Bridge. Highly Commended, T. Y. Craig. Cock Commended, J. Stocks.

COCHIN-CHINA (Chickens).—First, Mrs. Oswald, Dunnikier. Second, T. Y. Craig.

SPANISH (Chickens).—First, J. Macaully, Edinburgh. Second, A. Eates, Perth. Third, R. McGregor, Perth. Cock Commended, T. Knowles, jun., Aberdeen.

HAMBERG (Spangled).—First, R. Stewart, Kelly. Second, A. Penman, Kelly by Blair Adam. Third, D. Bluelock, Dumfermline.

HAMBERG (Pencilled).—First, A. Pratt, Kirkcaldy. Second, J. Ness, Pathhead. Third, D. Kilgour, Crossgates. Highly Commended, D. Bart, East Wemyss. Commended, J. Meiklejohn, Oakley.

GAME (Black and Brown Reds).—First, H. Goodall, Kirkcaldy. Second, W. Donaldson, Raith. Third, A. Spalding, Raith. Commended, T. Y. Craig. *Chickens.*—First, H. Goodall. Second, R. Stewart, Kelly, by Blair Adam. Third, R. Hutchison, jun., Braehed. Highly Commended, J. Steedman, Kirkcaldy. Commended, T. Baird, Auchtertool.

GAME (Grey, and others).—First and Second, P. Bernard, Leslie. Third, A. Spalding. *Chickens.*—First, T. Mathew, Leslie. Second, T. Williamson, Links. Third, J. Lyall, Links. Commended, W. Mitchell, Perth.

BANTAMS (Any variety).—First, R. McGregor. Second, D. Brown, Perth. Third, J. Speed, Leslie. Commended, W. Foote, Kirkcaldy; A. Haggart.

ANY OTHER BREED.—First and Second, Countess de Plahaunt, Tullyalan Castle (Cape Caur and Silver Poland). Third, Mrs. Roddick, Aberdeen (Brahma). Highly Commended, J. Middleton, Clayholes, Dysart (Silkie). Commended, Countess de Plahaunt (Buff Poland).

SELLING CLASS (Any Breed).—First, J. Stocks (Dorking). Second, R. Stewart. Third, J. Taylor, Tillycoultry (Dorkings). Highly Commended, G. Paul (Gold-pencilled Hamburgs).

SINGLE COCKS.

GAME (Any variety).—First, C. Jamieson, Forfar. Second, R. Stewart. Third, J. Gilmour, Milton Balgonn. Highly Commended, D. Brown, Perth; A. Spalding.

COCHIN (Any variety).—First, Mrs. Oswald. Second, Lord Loughborough. Third, T. Y. Craig. Commended, Mrs. Oswald.

HAMBERG (Any variety).—First and Third, A. Pratt. Second, D. Penman, Borland. Highly Commended, J. Ness, Pathhead; G. Paul.

BANTAM (Any variety).—First, R. McGregor. Second, A. Mills, Kirkcaldy. Third, D. Brown.

PIGEONS.

TUMBLERS.—First, J. E. Spence, Musselburgh. Second, R. Robertson, Kirkcaldy.

PASTALS.—First, J. E. Spence. Second, A. Crobie, Melrose. Highly Commended, T. Cooper, Carlisle.

ANY OTHER VARIETY.—First, H. Spence (Menly Pouters). Second, T. Cooper (Nuns). Highly Commended, A. Mills (Pouters). Commended, A. Spalding (Nuns).

CANARIES.

SCOTCH FANCY (Yellow Cocks).—First, R. Hunter, Oakley. Second, W. Bonthron, Kirkcaldy. Third, J. Tweedie, Kilty.

BUFF COCKS.—First, W. Bonthron. Second, G. Binney, Perth. Third, J. Kerr, New Scene, Perth.

YELLOW HENS.—First, W. Bonthron. Second, J. Smith, Dundee. Third, J. McGregor, Dundee.

BUFF HENS.—First and Third, G. Binney. Second, J. Stevenson, Dundee.

BEIJAN FANCY (Yellow Cocks).—First, S. Crawshaw, Lochec. Second, T. Kerr. Third, T. Hay, Dundee.

BUFF COCKS.—First, T. Kerr. Second, G. Laidlaw, Gala-hiels. Third, W. King, Dundee.

YELLOW HENS.—First, T. Kerr. Second, W. Bonthron. Third, G. Laidlaw.

BUFF HENS.—First and Third, S. Crawshaw. Second, W. Tinline, Gala-hiels.

FLEEKED (Yellow Cocks).—First, D. McDonald. Second, J. Smith. Third, W. Halkerston, Dundee.

BUFF COCKS.—First, J. Smith. Second, R. Hunter. Third, J. Ford, Freuchie.

YELLOW HENS.—First, A. Chalmers, Woodside. Second, R. Hunter. Third, W. Bonthron.

BUFF HENS.—First, J. Kerr. Second, J. Smith. Third, A. Clark, St. Clairtown.

MARKED GOLDFINCH MULES (Yellow Cocks).—First, J. Robertson, Aberdeen. Second and Third, W. Kirk.

BUFF COCKS.—First, W. Kirk. Second, A. Flenitig, Dysart. Third, T. Marshall, Pathhead.

SELLING CLASS (Any variety).—First, Second, and Third, Mrs. Wilson.

JUDGES.—Poultry and Pigeons: Mr. John K'path, Edinburgh; *Canaries:* Mr. John Mitchell, Perth; Mr. Robert McClelland, Dundee; Mr. Alexander Hope, Kirkcaldy.

CORK AND SOUTH OF IRELAND POULTRY SHOW.

The sixth annual Exhibition of this Association was held in the Athenaeum, Cork, on Wednesday and Thursday, the 2nd and 4th inst.

The following is the prize list:—

SPANISH.—First, R. W. Boyle, Dundrum, Co. Dublin. Second, R. P. Williams, Dublin. Commended, R. P. Williams; J. W. Dyas, Blackrock; Miss L. Pike, Besborough, Cork. *Chickens.*—First, R. W. Boyle. Second, Mrs. Dring, Rockgrove. Highly Commended, J. C. Cooper; R. P. Williams. Commended, R. P. Williams; J. W. Dyas; H. L. Tivy.

DORRINGS (Coloured).—First, R. P. Williams. Second, Mrs. Dring. Highly Commended, T. O'Grady, Roughgrove, Band n. Commended, T. O'Grady.

DORRING (Silver-Grey).—First and Second, T. O'Grady.

DORRINGS (White).—Prize, J. C. Perry.

DORRINGS (Crowned or White).—First, Mrs. Dring. Second, Mrs. Webb, Knocktoran, Knocklong. Highly Commended, T. O'Grady.

DORRINGS (Silver-Grey).—First and Second, T. O'Grady. Highly Commended, Mrs. H. Brown.

COCHIN-CHINA (Buff or Lemon).—First, R. W. Boyle. Second, F. W. Zurichst, Donybrook, Dublin. Commended, Mrs. Hay.

COCHIN-CHINA (Partridge or Grouse).—First, J. C. Cooper. Second, Mrs. Dring.

COCHIN-CHINA (White).—First, Miss L. Pike. Second, F. W. Zurichst. Highly Commended, F. W. Zurichst. Commended, J. C. Perry.

BRABHIA-POOTRIAS.—First and Second, R. W. Boyle. Highly Commended, J. Byrne; J. C. Perry. Commended, Hon. Mrs. H. B. Bernard, Coolmaine, Bandon.

CREVE-CŒURS.—First, J. C. Cooper. Second, F. W. Zurichst. Commended, Countess of Bandon, Castle Bernard; J. C. Perry.

GAME (Black or Brown Red).—First, J. C. Perry. Second, R. W. Boyle. *Chickens.*—First, J. Jeffry. Second, G. Lamtry.

GAME (Duckwings or Piles).—First, R. W. Boyle. Second, J. C. Perry. *Chickens.*—First, W. D. Alley. Second, J. C. Perry.

POLANDS (White-erected).—First and Second, J. C. Perry.

POLANDS (Silver).—First, Second, and Commended, R. P. Williams.

POLANDS (Golden).—First and Second, R. P. Williams.

HAMBERGS (Golden).—First, R. W. Boyle. Second, C. H. Cooper. Highly Commended, Mrs. Dring.

HAMBERGS (Silver).—First, Mrs. H. B. Bernard. Highly Commended, J. C. Perry.

BANTAMS (Sebright).—First, J. A. Fitzpatrick, Cork. Second, Hon. Mrs. Bernard.

GAME BANTAMS.—First, J. Dowling, jun. Second, J. A. Fitzpatrick. Commended, J. A. Fitzpatrick, N. W. Roche, F. Hodder, Cork.

JAPANESE SILKIES.—First, J. A. Fitzpatrick. Second, F. Hodder.

ANY OTHER VARIETY.—First and Second, J. C. Cooper (La Fleche and Malay). Highly Commended, F. W. Zurichst (Sultans). Commended, Mrs. Dring (La Fleche); J. C. Perry (La Fleche).

TURKEYS.—First, J. C. Cooper. Second, F. W. Zurichst. Highly Commended, T. O'Grady. *Poult.*—First, J. C. Cooper. Second, T. O'Grady. Highly Commended, R. Biscoe, Fermoy.

GESE.—First, R. W. Boyle. Second, J. C. Cooper. Highly Commended, J. C. Cooper; Countess of Bandon. *Goshies.*—First, Miss DeCide. Second, J. C. Perry.

DUCKS (Aylebury).—First, R. P. Williams. Second, J. C. Cooper. Highly Commended, R. P. Williams. *Ducklings.*—First and Second, R. P. Williams. Highly Commended, Countess of Bandon.

DUCKS (Roman).—First, N. H. Farrier, M.P., Cork. Second, R. P. Williams. Highly Commended, J. C. Cooper. *Chickens.*—First, W. H. Massey. Second, R. W. Boyle. Highly Commended, R. P. Williams.

ANY OTHER VARIETY.—First and Second, Countess of Bandon (Meyan and Muscovy).

SPECIAL PRIZES (open for competition to selling members only).—Silver Cup presented by F. W. Zurichst; F. W. Zurichst; F. Williams. The

Perry Medal, J. W. Dyas (Spanish). Mrs. Lyon's Medal, J. C. Perry (Spangled Hamburgs). Mrs. Harvey's Medal, T. O'Grady (Dorkings).

SWEEPSTAKES.

DORKING PULLETS.—Prize, J. C. Cooper. Highly Commended, J. C. Cooper.

SPANISH PULLETS.—Prize, Mrs. Dring. Highly Commended, J. C. Cooper.

PIGEONS.

POWTERS (Yellow Pied).—First, J. Montgomery. Second, Dr. Harvey. **POWTERS (Black Pied).**—First, J. H. Perrott. Second and Highly Commended, J. Montgomery.

POWTERS (Blue or Silver Pied).—First, J. Montgomery. Second, J. H. Perrott. Highly Commended, J. H. Perrott. Commended, J. Muir. Dr. Harvey; A. E. Usher.

POWTERS (Red Pied, Mealy, or other Colour).—First and Second, J. Montgomery. Highly Commended, Rev. T. Townsend; J. H. Perrott. Commended, A. W. Shaw.

POWTERS (White).—First, J. Montgomery. Second and Highly Commended, J. H. Perrott.

CARRIERS (Black).—First and Second, G. A. Wherland. Highly Commended, R. Lane; Dr. Harvey. Commended, C. A. Wherland; H. L. Tivy; R. Fulton.

CARRIERS (Dun).—First, Dr. Harvey. Second, G. A. Wherland. Highly Commended, R. Lane; G. A. Wherland. Commended, T. Clarke; J. Muir.

CARRIERS (Blue or other).—First and Second, G. A. Wherland.

ALMOND TUMBLERS (Short-faced).—First, Second, and Commended, A. W. Shaw.

TUMBLERS (Short-faced Almond).—First and Second, Dr. Harvey. Commended, J. B. Ellenrassett; J. Lloyd.

TUMBLERS (Short-faced Mottles and others).—First, A. W. Shaw, Lime-ick (Black Mottles). Second, R. Fulton, Deptford, London. Highly Commended, R. Lane, Cork (Black Mottles).

TUMBLERS (Short-faced Balds or Beards).—First, Dr. Harvey (Blue Balds). Second, A. W. Shaw (Blue Beards). Highly Commended, Dr. Harvey (Blue Balds).

TUMBLERS (Common Balds or Beards).—First and Second, A. W. Shaw (Black Balds and Blue Beards). Highly Commended, J. Dowling, Black-rock (Yellow Balds).

TUMBLERS (Common, any other colour).—First, J. Pike, Besborough, Cork. Second, P. Lane (Black Mottled).

BARBS (Black or Dun).—First and Second, G. A. Wherland. Highly Commended, J. H. Perrott, Hayfield, Cork; A. E. Usher, Camphire, Coppoquin.

BARBS (Any other colour).—First, G. A. Wherland (Red). Second, J. H. Perrott (Red). Highly Commended, G. A. Wherland; J. H. Perrott (Yellow).

JACOBS (Red or Yellow).—First, J. Lloyd. Second, J. Pike. Commended, G. A. Wherland.

JACOBS (Any other colour).—First, J. Perry (Mottled). Second, T. Clarke, Cork (Mottled).

FANTAILS (White).—First, J. H. Perrott. Second, T. O'Grady, Rough-grove, Bandon. Highly Commended, G. A. Wherland. Commended, T. Clarke; J. Pike.

FANTAILS (Any other colour).—First and Second, J. Pike (Blue).

OWLS (Blue or Silver).—First, A. E. Usher. Second, J. H. Perrott. Highly Commended, A. E. Usher.

OWLS (Any other colour).—Prize, J. Pike (Yellow).

TRUMPETERS (Mottles).—First and Second, J. H. Perrott.

TRUMPETERS (Any other colour).—First, J. Perry (White). Second, T. O'Grady (White).

TURBOTS.—First, T. O'Grady. Second, J. Dowling. Commended, Rev. T. Townsend, Bandon.

NUSS.—First, J. Dowling. Second, A. E. Usher.

MAUPERS.—First, Rev. T. Townsend. Second, E. M. Roys, Rochdale.

ANY OTHER VARIETY.—First, J. Perrott (Brunswick). Second, Dr. Harvey (Brunnen Powters, White). Highly Commended, Dr. Harvey (Brunnen Powters, Black).

SWEEPSTAKES for Pigeons, hatched in 1865, and bred by Exhibitor.

POWTER (Any colour).—Prize, J. Montgomery, Belfast (Black). Highly Commended, J. Montgomery; Dr. Harvey (Red). Commended, R. Fulton.

CARRIER (Black).—First, R. Lane, Cork. Highly Commended, G. A. Wherland, Cork. Commended, J. Muir, Glasgow.

CARRIER (Dun).—First, Dr. Harvey. Highly Commended, J. Muir.

SPECIAL PRIZES FOR PIGEONS.—Silver Cup (presented by the Society), G. A. Wherland. Silver Medal (presented by Patrick Goulding, Esq.), G. A. Wherland (Black Carriers). Commended R. Lane. Silver Medal (presented by G. A. Wherland, Esq.), J. Montgomery (Red Powters). Commended, J. H. Perrott (Black Powters). Silver Medal (presented by Henry Hawkins, Esq., Belfast), Medal and Commended, G. A. Wherland (Black Barbs).

SONG BIRDS.

CANARIES (Yellow).—First, A. Veitch. Equal First and Second, F. M'Loughlin.

CANARIES (Green).—Prize, H. Keating.

MEALY (Any other colour).—Second, A. Veitch (Buff Pied).

GOLDFINCH MULES.—First, J. Fitzgerald. Second, H. Keating.

BLACKBIRDS.—First, J. Fitzgerald. Second, J. Perry.

THRUSHES.—First and Second, W. Waters.

SKYLARKS.—First, J. Lennie. Second, E. Daly.

BULLFINCHES.—First, J. Dowling, jun. Second, H. Keating.

GOLDFINCHES.—First, H. Keating. Second, J. Fitzgerald.

LINNETS.—First and Second, J. Dowling.

TRIMMING COMBS—VULTURE HOCKS IN COCHIN-CHINA.

I SHOULD be very glad of a reliable opinion on the subject of one or two of the points of Cochins. My birds seldom breed a cockerel without a side sprig to his comb. Is this considered

by Judges to be a very serious defect in the case of a bird whose other points are good? To take a particular example: I have a Buff cockerel over 11 lbs. in weight. His only defect is that the last serration but one of his comb has the appearance of being split down the middle, making two sprigs instead of one, and both slightly leaning on opposite sides. I know that it is a custom of dealers to cut off a side sprig while the bird is young, and that, after the comb has been developed, this in most instances cannot be detected; but is this, I am assured general, practice considered fair and straightforward?

Another point on which I should be glad of further information is that of vulture hocks. Many birds have a slight apparent tendency to this fault, in which I do not think that it should be considered a serious defect—I mean where the feathers behind the knee, though quite fluffy and soft, are slightly pointed, but without projecting stiffly and beyond the other leg feathers? Indeed, are not almost all birds with very heavily feathered legs subject to this drawback? This, too, is a case where, I am told, birds are trimmed every day beyond the possibility of detection. Is it not, therefore, a pity that so great a stress is beginning to be laid on a point which, except in the case of the objectionable stiff feathers, is rather an exuberance than a defect, and which may be so very easily removed by trimming?—*CLERICUS.*

[It is a very common practice to trim slightly the combs of Cochins and Spanish. In both breeds any approach to double comb is a disqualification, and the suspicion of it is therefore avoided. The practice is not confined to dealers, but is common, we believe, to all. It is not considered unfair, but in deciding between two birds of equal merit the trimmed comb would turn the scale against its possessor. A razor or very sharp knife is used for the operation, and the "sprig" should be removed by cutting downwards. This leaves little trace, but a practised eye can always detect it. Vulture hocks are only recent introductions into the Cochins, and should be discouraged. Detection is easy if the feathers are cut off, difficult if they are pulled out. Careless breeding has introduced these faults. Birds have been selected for the sake of new blood, and for the introduction of some point in which they excelled, but which also possessed a failing. Both have been inherited, and sufficient pains have not been taken to breed out the fault. A pen with very moderate beauties, but without one real fault, must be successful over another of great excellence, but with an admitted fault.]

[The foregoing is from the pen of one of our most able poultry Judges, and we will only add a few words on the subject of vulture hocks. We had Buff Cochin-China fowls with these hocks as long since as 1850. They were from Mr. Sturgeon's stock. The Poultry Club, in its standard, says the vulture hock is objectionable, but not a disqualification. We cannot assent to its being objectionable, for we consider that it adds to the good figure of the bird. This is a matter of taste. If poultry fanciers agree in reprobating vulture hocks, breeders have no alternative—they must aim at producing birds without them.—*Eds.*]

FOUL BROOD.

I HAVE delayed writing on this subject until I could give a full account of the results of the summer's experience. I will now describe what has taken place in my own and my neighbour's apiary.

In October, 1864, No. 187, was detailed the means which my neighbour took to free his hives from the disease, by beating out the bees into clean skeps, and the result has been, that not a single diseased cell has since been seen in all his stock of fourteen hives. In order to ascertain if honey from diseased stocks given to a young hive would be the means of causing the disease, after the other hives were sent away to the heather he kept a young hive at home, and found an eke below it containing a quantity of foul brood and honey, which was cleaned out in two days, when it was removed. He also gave the same hive five skeps to clean out, one after the other, all having foul brood and honey. That same hive gave off its first swarm this year on the 4th of June, and as yet all the other swarms it sent off, as well as the old one, are free from foul brood. This case is so different from that of some of your correspondents, that it adds to the mystery of the cause of foul brood, and how it may be cured.

While my neighbour has succeeded in entirely freeing his apiary from this disease after having it so long, I have now to

report that I found it in two of my hives after they had come from the heather. It was only in one bar of each, and about half the size of a man's hand. I allowed it to remain to see if it would extend further, or to see if the bees could clean it out of the cells. I examined them on the 14th of December, and found that all the cells were cleaned out with the exception of eight or nine, and these were in progress of being cleaned out also. I found a large quantity of brood in all stages in the hive, and all in good health. I have never known a hive of mine breeding in December before. The queen is the Ligurian which Mr. Woodbury sent in a small box in 1863.

I cannot account for the disease being in these two hives, while I have other twenty entirely free from it, all being treated alike. It had occurred to us that it was possible that a hive might be overheated during its removal to the heather from want of sufficient ventilation, but the hive to which I allude was not sent to the heather, as I was not disposed to risk it on such a rough journey.

I had a case during the summer which I thought at one time would go far to prove that Mr. Lowe was right in regard to chill being the cause of the disease, and that those, along with myself, who hold a different opinion, would require to acknowledge their mistake. For myself I can truly say that none would have been more ready to have done so had such been the case.

In order to observe the whole proceedings in the interior of the hive, I had one made with glass sides, and only one comb in breadth, so that both sides of the comb could be seen at all times. It was made to contain four Woodbury bar-frames, which can be removed, and others substituted in their place, when required. During a hot day in the summer, while trying to put some combs straight which the bees were not building properly, two of them broke down, and the queen was killed, although I was not aware of it. Two-thirds of the bees left at the time, and a quantity of honey was taken by the other hives, but one-third of the bees remained with the brood, and were rearing three young queens, when I removed the four bars into my observatory hive. Two of these bars had a large quantity of brood in all stages, the other two had only a few in each. There were just as many bees as covered the two bars, and about one hundred bees remained with the young brood on the other two, but they were unable to keep up the heat, so that the grubs died, and all turned black, the bees leaving them entirely. Here, thought I, it is where Mr. Lowe was right, and myself wrong, and I was about to write and admit it, but deferred until I saw the result. When a queen was hatched, and laying eggs, as the young bees filled the hive they began and cleaned out all the dead black grubs, leaving the cells as clean as ever they were; but although that brood remained in the cells six or seven weeks after death, it never passed into corruption like diseased brood; so that I am more than ever convinced, that whatever foul brood may be, it is something more than a chill to the young brood, and that by removing the combs of foul brood as it appears, and putting the bees into clean hives, it can be mastered. It is only by good sanitary measures, carried out thoroughly with bees, as well as with everything else of the animal kingdom, that we can ever expect them to thrive.—ALEX. SHEARER, *Yester Garden.*

[Your neighbour's experiment proves the truth of Dzierzon's statement, that honey taken from foul-breeding stocks may be given with impunity to healthy colonies in the autumn, because during winter it is in the absence of brood all consumed by adult bees. For the same reason simple excision at that season may, and sometimes does, work a radical cure; and it appears even possible that, favoured by the cessation of breeding, the bees themselves may, unaided, work their own salvation in cases wherein the disease, being recent, has not progressed to the virulent stage.—A DEVONSHIRE BEE-KEEPER.]

DYSENTERY IN BEES—LIGURIANS.

I AM, or I think I may say we are, much obliged to the "DEVONSHIRE BEE-KEEPER" for his able article on dysentery, and I think Dzierzon is correct in many of his reasons for it; but I do not fancy that the hives have anything to do with it, or feeding late, as I had five straw skeps, and all were fed nearly alike, but only one suffered from this disease. I shall be glad to hear from others of your correspondents upon this subject.

Two of my Ligurian stocks have turned out crossed with

black drones, although they have Ligurian queens. Will there be any risk, by keeping them among the others, of their drones crossing with the true Ligurians again, and making them hybrids?—A. W.

[If the queens themselves are really pure bred, they will breed pure Italian drones (but mixed workers) in spite of the first cross.]

CROWN-BOARDS.

WOULD a wooden frame 1½ inch thick and 2½ inches broad, filled inside with straw bands and sewed with cane, be more suitable for the tops of Woodbury hives than wood tops?—I. T.

[Straw crown-boards (if the misnomer may be allowed) made in the manner you describe, would, we think, be better than the ordinary wooden ones.]

OUR LETTER BOX.

WEIGHT OF DORKING COCKS (*Constant Reader*).—"Upwards" certainly means "above" 10 lbs.

DORKING COCK'S COME (*Chateau Fallon*).—The two combs, hollow in the middle, but joining at the points, form what is called a cup comb. It was very common of old, and is so now in the poultry districts. It was not fashionable, and was therefore discouraged at exhibitions. It is not only no disqualification, but occurs in birds as pure bred as any having single or double combs.

PEA FOWLS (*S. D.*).—Pea fowls are always considered destructive in a garden.

INCUBATOR (*Theo*).—The incubator we have spoken of lately is not yet advertised.

SHIFTING FOWLS (*T. E.*).—We do not think your fowls would be injured by being removed in a basket every night, but we would suggest straw at the bottom instead of paper. The plumage may be washed with soap and water, put on and wiped off with a sponge. The outer part only of the feather wants washing; and when it is clean the bird should be put in a basket with clean hay or straw, and placed before the fire till quite dry. Some use soda, but it is found to be injurious to the feather.

SPANISH COCK'S COME FALLING OVER (*Spanish*).—Alteration in diet will sometimes have an effect upon the combs. Old fanciers used white peas for the purpose; they are said to harden plumage and comb. It is more often the result of breed. Some are more prone to fall over than others. We would never breed from such.

COCHIN-CHINA FOWLS DEFICIENT IN SIZE (*Norice*).—Chickens to be large must be well fed when young, but over-feeding is no advantage to a fowl at any age. When, however, you say all take their luck together, what luck is it? Do they live in a fowl yard? Have they means of obtaining any other food than that given to them by hand? We advise you to keep all together, and to feed well, then to select the best for exhibition. Staked meal morning and evening, whole corn at mid-day, grass, lettuce, table and kitchen scraps, constitute good feeding.

BANTAM HEN (*M. S.*).—She is overfed. The soft egg, &c., are evidence of over-fatness. Feed her by herself very moderately; chiefly boiled potatoes and plenty of lettuce leaves.

DORKING COCK'S WING BROWN (*J. H. Tring*).—No colour can disqualify the bird you mention unless he were black or white. The dark brown in the wing is not even a disadvantage. Dorkings have no special colour unless they are shown as Silver-Grays.

"C. E.'s" letter is received, and will be noticed next week. This and some other subjects are unavoidably postponed till our next Number.

AUSTRALIAN GLASS PARROQUET PANTING (*G. M. E.*).—The panting of your bird arises from its being too fat. We would recommend you to withdraw the maw seed, it is too stimulating and binding, and let it have Canary and a small quantity of millet; scald some oats for about twenty minutes, and let it have a few, also a few net scabbled and a tuft of the longest grass you can obtain; try also a little soaked bread and milk.

CLEANING FLOOR-BOARDS (*J. K. E.*).—Your stock being well provisioned and populous was the reason of so many bees congregating on the floor-board, and in such a case there was little need to disturb them, so saving a colony being well able to deal with impurities as they arise. The middle of a fine day is the best time for changing floor-boards, as well as for performing most other operations, and your mode of proceeding was a very good one.

FEEDING (*Prosper*).—We had lump sugar dissolved in water, in the proportion of three parts by weight of sugar to two of water, and boiled a minute or two, an admirable substitute for honey in feeding bees. "Fruit Gardening for the Many" can be had free by post from our office for five postage stamps. It contains directions for teaching pruning.

POULTRY MARKET.—JANUARY 8.

THERE is a good supply of poultry, and a fair demand. The sorts are very plentiful, and well-bred.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 42.8; and its night temperature 31.5. The greatest heat was 60°, on the 19th, 1828; and the lowest cold 41° below zero, on the 19th, 1838. The greatest fall of rain was 0.87 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

ACHIMENES CULTURE.

Y "A CONSTANT READER" information is sought on this subject, and the following, in answer to his inquiries, may be of service to others as well.

The Achimenes is a plant easily cultivated, and, though requiring a higher temperature than that of a greenhouse, will, nevertheless, do well there after June, when, for the most part, there is a deficiency of blooming plants in such structures. Achimenes also succeed well in a heated vinery.

Early in February the bulbs are taken out of the pots in which they have been grown the season before, and are laid pretty thickly on the surface of a pan filled to within an inch of the rim with a compost of two-thirds light turfy loam, and one-third leaf mould. They are then covered with half an inch of fine soil. If the soil is in a moderately moist state no water is given, but if dry a little is afforded to bring it into a moist condition. The pans are then placed in a hotbed of about 75°, and a top heat of 60° or 65° by night. Here they remain until the shoots are an inch long, when the plants are placed in their blooming pans.

Achimenes never look so well as when grown in pans. The sizes which I think most eligible are 12 and 18 inches in diameter, and 8 inches deep. The first size allows of nice specimens being grown, and the second of very fine ones. The pans should be clean, and have good-sized crocks placed over the holes, which should be five in number, and not less than half an inch in diameter. Above these crocks lay an inch of broken pots, then an inch of the riddings of the compost, and fill up to within an inch of the rim with a compost of two-thirds loam from rotted turves a year old, cut 3 inches thick, placed in alternate layers with fresh horse-dung, turned over twice, and, previous to use, chopped fine with a spade, but not sifted; one-third leaf mould, three parts reduced, sifted to free it of sticks, &c., and well mixed with the loam; and one-sixth of silver sand. The plants are then taken up with a stick, and a row of the smallest placed around the pan half an inch from the rim, and exactly an inch apart; put in another row 1 1/2 inch from the first, and an inch apart, and so on to the centre of the pan, which should be a little higher than the sides, say an inch for an 18-inch pan. The smallest plants are put at the outside, the next largest in the next row, and so in order to the largest in the centre. A gentle watering is then given, and the pans are placed in a house with a moist atmosphere (as that of a vinery at work), and with a night temperature of 60°, bearing in mind that the nearer the plants are to the glass and light the stronger they will grow, and, unless they are

still and strong, it is vain to expect a good bloom. Water sufficiently to keep the soil moist, but do not deluge them, nor, on the other hand, allow them to suffer for want of it. Never give water unless they seem in want of it, the leaves are not to be allowed to flag, but when the soil appears dry, and is so to the feel, give a good watering. A gentle syringing with water of the temperature of the house will be of advantage up to the time of the blooms expanding, but avoid syringing in dull weather, and let the leaves be dry before the sun shines powerfully upon them, otherwise they may spot. If drip from the roof fall upon the pan, either stop the leak or remove the pan at once. Should green fly make its appearance, fumigate with tobacco when the plants are dry. Thrips will not interfere, unless the atmosphere is much too dry; if they do, tobacco smoke will destroy them.

When the plants are from 3 to 6 inches in height they will need tying; the sticks should be small and neat, made of laths, and painted green. They ought to be not less than 18 inches long, whilst for some kinds 2 feet will be better. A space of an inch or so was left below the stem at the time of potting; this should now be filled up with a mixture of equal quantities of the previous compost, passed through a half-inch sieve, and containing one year old latten and also passed through the sieve, with the addition of one-sixth of silver sand well mixed in. This, placed upon the surface between the plants to a depth of three-quarters of an inch or an inch, will, after a time, show its effects in the strength of the plants and the bloom. Commencing with the centre, one stake is to be put to each plant, and the plant loosely fastened to it in an erect position with a thin strip of bast matting. Continue the upright staking until the second row from the rim is reached, then every alternate plant of that row should be staked upright, and the others inclined from the perpendicular towards the rim of the pan. Every second plant in the outer row should be staked with an inclination corresponding to those staked upright in the second row, and at an angle of 45° from the perpendicular of the pans rim. Side shoots will be produced; do not tie them, but let them grow loosely, but, if they become as strong as the main shoots, and are straggling, they should be staked. Continue to keep the shoots tied up as they grow, and, when the buds show, every alternate watering may be of weak liquid manure until the plants are fairly in bloom, when they require a plentiful supply of water.

The plants will be in bloom in the end of June and in July; those in 18-inch pans will be fine masses of bloom from 12 to 18 inches high, and from 2 feet to 2 1/2 feet through. Their beauty will be prolonged by placing them in a drier and cooler atmosphere, where they can be slightly shaded, as in a greenhouse or conservatory not highly ventilated. When the bloom is over they should still have a light situation, and the supply of water ought to be diminished, and, when the foliage becomes brown, it may be cut away, and the pans placed on a damp shelf or in a dry place, as under the shelves of a house, having a temperature of not less than 40° nor exceeding 55° from fire-heat.

the Bois du Boulogne, the La Muette gate, at the extremity of the fashionable quarter of Passy, this establishment covers an area of nearly five acres between the Rue de la Tour, the Avenue de l'Empereur, and the old historical castle of La Muette. The railway between Auteuil and St. Lazare cuts the ground into two unequal parts, of which the smaller is taken up by frames, the orangery, sheds, cellars, &c.

The frames are more especially intended for raising plants from seed, and for the extensive propagation of softwooded plants for bedding, such as *Pelargoniums*, *Verbenas*, *Calceolarias*, *Salvias*, *Fuchsias*, *Chrysanthemum frutescens*, &c. There are altogether 2300 lights set in straight lines, and arranged in sections according to the description of plants grown in each. The frames are shortly to be replaced by a range of fifty low houses communicating with each other, and forming the most complete assemblage of glass houses ever seen. Each section is in charge of an under-foreman under the general direction of the foreman, and he has two or three assistants, with whose aid he has to manage from 100 to 150 lights. He alone is responsible for the plants, also for the breakage of glass, and other casualties arising from carelessness, and as a compensation he receives a small monthly allowance. The advantages of this system are, that the workman takes better care of the plants and materials committed to his charge, economy is consequently secured, and the men, being confined to one department, speedily gain great experience of the particular plants with which they are engaged. To give an idea of the immense number of plants raised at the *Fleuriste de la Muette* (that is the name of the establishment), I may state that it amounts to nearly 3,000,000 a-year, *Pelargoniums* alone counting for 250,000, *Cannas* for 70,000, and other principal genera in proportion.

The orangery or conservatory, constructed in a very economical manner, is 226 feet in length, and is used for the protection in winter of hardwooded plants taken up in autumn for planting-out in the following year. A large shed of the best construction serves to shelter soils, peat, and various composts, as well as spades, rakes, watering-pots, and light tools. Down the middle for the entire length of the shed runs a table 18 feet wide, at which sixty men can put with freedom the innumerable plants struck from cuttings in the frames. Spacious cellars, 9 feet 10 inches high, cut out of the rock at great expense and at a considerable depth below the surface, extend beneath the frames. They are intended for protecting in winter tubers and rhizomes, such as those of *Luhlias*, *Cannas*, &c., taken up in autumn. They may also be used as a workshop for the gardeners in severe frosts, and as gas will shortly be laid on, they will be still better adapted for the purpose.

On the other side of the railway are the trial ground and glass houses. Whenever a new plant is announced it is purchased at any price, and here tried, for the city of Paris will not lag behind in the race of gardening progress. If the plant is hardy it is grown on trial out of doors along with kindred plants, and under different modes of culture, and after two or three years' experience it is adopted or rejected; but it must possess many good qualities to dethrone its rivals, and be extensively propagated. The effect is here studied, especially in masses of one species or variety, rather than in heterogeneous assemblages of plants without unity or harmony. The trial is all the more severe, because long experience has taught mistrust of the high-sounding, often specious, descriptions given by dealers in novelties. If the plant is adopted it is sent to Vincennes, where it can be propagated in such numbers, and over an extent of ground, that it could not be at La Muette.

The houses, which have been successively erected from 1858 to the present time, are not equalled in extent in any other part of France. They consist of twenty-one ranges, divided into sections according to the mode of culture required by the different classes of the plants, and cover an area of 95,800 square feet. The largest house has an area of 18,222 square feet, is 31½ feet in height in the centre, and is in three compartments. The central one is filled with a splendid collection of *Camellias* from 15 to 2½ feet high, planted out, and several of them once formed part of the celebrated collection of the Empress Joséphine at Malmaison. Of the two side divisions one is devoted to the protection of those ornamental-foliaged plants which have risen so much in favour during the last few years. There may be seen trees of *Wigandia*, *Nicotiana wigandioides*, which is covered in winter with superb drooping panicles of white flowers, *Montanas*, *Polymnia*, *Aralia papyrifera*, and many

other handsome tropical plants. The division on the other side contains a number of large specimens *Palmæ*, *Pandanus*, and *Cycads*, which are almost unrivalled. Among them are magnificent examples of *Sabal Blackburiana*, *S. ventralis*, *Pandanus*, *Phoenix*, *Thrinax*, *Livistonia*, *Zamia*, *Cycas*, *Ceratozamia*, &c., not to mention a numerous collection of novelties, in fine condition, amounting to upwards of 300 species. Another large house, in three spans, holds the remainder of the collection of large *Camellias*; these are in full, and whilst these plants last afford a multitude of cut blooms, these are used to decorate the apartments of the Hotel de Ville at the great balls given by the Prefect of the Seine; indeed, all the large stove and greenhouse plants are principally grown for this purpose. Ordinary greenhouse plants, such as *Azaleas*, *Acaacia*, *Epicurises*, *Heaths*, &c., are grown along with the *Camellias*, and receive much the same treatment as regards culture.

A square pavilion, filled with very tall *Palmæ*, *Dreconas*, *Ficus*, *Analia*, &c., forms a vestibule to a high building containing a collection of no less than 110 species of *Ficus*. *Ficus elastica* (*Vro-tigma elastica*, or the Indian rubber tree), takes up the greatest amount of room, although there are some other species of nearly equal merit for beds of peat and out of doors in summer.

Further on, in sections according to the description of plants grown in them, are large and fine houses devoted to *Præcoxas*, to *Aroids*, to *Berberis*, to large-leaved *Solanum*, to *Berberis*, to *Musa*, to *Hibiscus*, to *Pelargonium grandifolium*, to large *Caladium*, &c. Lastly, other two houses deserve special mention; these are the propagating-house and that which goes by the name of the "serre de sevrage."

The propagating-house is employed for the rapid propagation of all herbaceous and hardy plants that do not strike readily in frames, and the appliances are such as are now almost to be seen. It is impossible, however, to convey a full idea of the arrangements from mere description; suffice it, therefore, to say that there are shelves all round, and between two bark beds, in the interior of which shelves rise in imitation like the steps of a stair, and under these run the water-pipes enclosed by sheets of iron. The pipes, taken in number, are 4½ inches in diameter, and run all round the house. Being thus confined within the pipes, they maintain the heat of the tan in which the pots are plunged, and afford that degree of bottom heat which is so favourable to the emission of roots. The step-like arrangement of the shelves covered with tan, on which bell-glasses are placed, allows of the young plants being kept very close to the glass. Six young gardeners are employed throughout the year in propagating, and for plants difficult to strike or raise from seed special means are provided. This house furnishes about a million of young plants every year.

The "serre de sevrage" is that in which the young plants are placed as soon as they have recovered from their first transplantation or potting, and when they are well established they are removed to their respective houses or frames to make way for new comers. A portion of this house is occupied with choice specimens of new stove plants on trial, or for propagation.

I may add that the other branches of this establishment, such as seed-rooms, storerooms, &c., are well organised, and that the regulations are most judicious, and so too are those with regard to the superintendence, order, and discipline of the men. Lectures on the theory and practice of horticulture are periodically given by the heads of departments to the workmen and apprentices, and discussions held. The expenditure for this great establishment does not exceed £8000 a-year.

Such is the organisation of an establishment of the like of which does not exist in the whole world, and which proves what horticulture can do for the ornamentation of the capital of a great nation.—*Ed. ANDRÉ, Jardinier Principal de la Ville de Paris.*

IRECINE HERBSTII.

ALLOW me through your valuable Journal to say a few words on behalf of the *Iresine Herbstii*. I planted a bed of it in this garden last season, and although we had a large number of beds planted in the usual way with bedding plants, not one was so much admired as the above, more especially during the months of July, August, and September—in fact, it was beautiful up to the middle of October. I also consider it invaluable for the stove for this season of the year. I have some fine specimens in eight-inch pots 2 feet through, and

about the same in height. Therewith enclose a portion of the same for your inspection. The plants from which they were taken are growing in a temperature of about 65° or 70°.—Isaac *Journal of Horticulture, The Bot.*

The specimen leaves were very deep-colored, and fine.—*Ed.*

GLANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 19.

As before, we remained in Florence showed us more and more of the condensation change that had fallen upon that city of mine. On every side life and activity had taken the place of the former calm repose. And such strange life too! I stood and wondered how faculties that had remained so long unused could all at once have burst forth into such active play. I was like a very child rushing into the shop-windows, reading the "sheet of books, pamphlets, and newspapers—halfpenny newspapers—perhaps a trifle too scurrilous, a trifle too free with the names of king, ministers, and people; and I must confess I saw their hair sometimes standing a little on end at only the titles of the publications. The great reaction seems to have been too much for the heads of the good people of Florence; they are like thirsty men, unaccustomed to strong drink, placed before an overflowing tankard, they think more of quenching their thirst than of after-consequences. I comforted myself with thinking that after awhile these wrongs would right themselves.

Another strange feature was the churches. On many sides I heard murmurs of the persecutions to which the church was subjected, long faces were pulled, and the direst prophecies uttered as to what would be the future result. The future was beyond my ken; but the present, as far as the Church of Rome went, seemed highly satisfactory. I saw, indeed, fewer monks and priests, but more services; less show perhaps, but more reality. I found churches filled with praying people, that once were comparatively empty, and judging by what I saw my impression was that the Church had received freedom rather than persecution. Of course there was, what some people would call, the reverse side of the shield. I thought so when I drove to what once had been the Farmaceutica of St. M. Novella, where the dear old white-robed monks had used to distil the most fragrant essences from delicious flowers, and make "perfumelle di profumi" of wonderful potency; but alas! the few monks that had been left had no time to distil aught but sad forebodings to their ancient house and to do the red work of the convent; so we had to return without pastils or scent, if I except the flavour of garlic, which seems to pervade every monk and monastery as inseparably as the smell of peat pervades an Irish beggar through years of mendicancy in England.

Again, when I went to see the matchless frescos of Fra Angelico in the convent of S. Marco, and found soldiers expected there, I thought it was the reverse of the shield with a vengeance! and it brought to my memory that it was not the first-time soldiers would invade the convent of Savonarola and Fra Bartolomeo. There are no paintings in Florence that I more love to look upon than those of Fra Angelico; it seems as if the reflection of the inner life of the good "frate" shone brightly and purely on every feature of the blessed angels he loved so much to depict.

One of the favourite drives from Florence is to the Carthusian Monastery of La Certosa in Val d'Emo, from whence the monks distribute food and medicine to the poor for many miles round. There are many beautiful wild flowers growing around the convent, and amongst them a large rugged-looking Peony of a pinkish lilac colour, which was flowering in great profusion. I believe it to have been the *Peonia peregrina*. I have never seen it growing wild in any other locality.

In the fields near Belosquardo, shining brightly amidst the fresh green corn, I gathered quantities of *Glabidus communis*, the colour being quite as good, though the spikes of bloom were not so large as when under cultivation in England. The fields of Italy are so richly decked with flowers in all the wild luxuriance of Nature untouched by art, that I grew to love them better than the untidy gardens, suffering from the spasmodic operations of gardeners who thwart Nature without introducing anything.

From the beautiful fields I passed into the garden of the Villa Belosquardo, and there I saw Orange trees, full of fruit and in bloom, in large tubs filled with the very richest compost.

its ugliness so unconcealed that one turned away disgusted from the golden fruit and full rich blossom. Beneath the walls of this villa there is a magnificent view of Florence; we went there to watch the setting sun. All around us were bushes of Roses—the common China and the Yellow Bank-sian, the latter trailing its burnt blossoms over walls and trees, from which it depended in innumerable festoons reaching almost to the ground, where the deep blue Corn-flower (*Centaura cyanus*), was growing in pleasing contrast of colour. Below us lay Florence, with her graceful towers, her gently flowing Arno, with the silvery gleaming Birch trees by its side, while stretching far away was a dreamlike distance of fair soft grey hills, with pleasant-looking villages dotted about the intervening valleys. To the right was the tower of Galileo; and as the eye gazed upon it strange thoughts would come to the mind of the curiously one-sided nature of the Pope's infallibility—"so infallible," as a Catholic in Rome said to me one day, "in spiritual matters, so very fallible in all temporal affairs." One could not but remember the strange scene in the convent of Mirra in Rome, when Galileo, then seventy years of age, was forced, some say by torture, to abjure on the Gospels his belief in the Copernican doctrine, arising from his knees, we read, that the old man turned to a friend, and whispered, "*E pur se muove*," "It," the earth, "moves for all that!" but as there was no little bird to whisper in the ears of Pope and Inquisitors Butler's famous epigram—

"He who consents against his will
Is of the same opinion still."

I trust they were satisfied that the imposed oath had settled the question and the earth's motion together.

But I have wandered far away from Belosquardo, and from the low wall on which we sat watching and listening. Presently from a neighbouring villa came forth a pretty-looking lady, work in hand, and by her side two little children, one holding his father's hand. They, too, came and sat down, the pretty mother working and clapping away, while the children played at bo-peep with their parents and the stranger. Then there came a party of monks in brown habit, rope girdle, and sandals; with eyes bent on the ground they passed quickly on, sitting down at a little distance, when forthwith, mingled with the scent of Roses, came the abomination of garlic. With the monks came a small party of young lads in the black cassock and felt hat of the seminary. Then arrived a party of Americans with a courier, Murray, and cigars. Striding the wall as though it were a mule's back, they puffed away in total defiance of the "smoking prohibited" that English ladies carry so plainly written on their faces. Happily they soon "did" the view, hurrying on to another, while a trio of Italian girls took their place, the sweet music of their tongue blending in perfect harmony with the scene. We were a strange party, attracted from such distant lands to gaze on the glory of that setting sun, sinking down so peacefully behind the western hills.

It was in Florence that I noticed for the first time the *Cercis siliquastrum*, or Judas Tree, its clusters of red bloom having much the appearance of a red Acacia. Here, also, I met with the *Petunia nyctaginthiflora*, or Petunia Tree; the blossoms are of the softest lilac, with a grey tinge, they hang in drooping masses, and have a most delicious scent. The tree is as large as a moderate-sized Apple tree, and is most graceful-looking. Cheap as bouquets were in Rome, they were much cheaper in Florence, and much more beautiful; for half a paul I could buy the most lovely Roses and Lilies, and, what is more, I could choose my mesagey from a huge basket of flowers freshly gathered, with the morning dew still resting upon them, and, moreover, I could have a long chat about them into the bargain. Some of the streets are quite converted into gardens, quantities of shrubs and plants being arranged against the wall, and railed round. How I longed to put felonious hands through the bars and gather for myself! There were Roses, yellow, white, and pink; *Deutzia gracilis*, with its feathery white blossoms; Coronilla, and a hundred other dainty flowers. I wondered how they would have looked after a two-days sojourn in Regent Street.

One of the most interesting sights of Florence is the royal manufactory for the "picche commesse," or Florentine mosaics, where the most finished pictures are wrought in precious stones, and the workmanship is so delicate that these inlaid mosaics may be easily taken for paintings, and the groups of flowers look so natural, one is half tempted to try if they have any scent. The marbles and stones of which the mosaics are composed are collected from every country under heaven,

so that in one small space, not larger than your hand, you would see the treasures of the most remote lands brought together; there would be dark agate from Derbyshire, petrified wood from Hindostan, opals from Hungary, turquoise from Persia, &c. The work is very slow and tedious, so that it takes nearly twenty or thirty years to finish any great undertaking! In the time of the ex-Grand Duke I went to see the unfinished monument of the first Grand Duchess, when the second had grandchildren! The opals are the most difficult stones to manage, as it is necessary to set them in a hollow space, whereas all other stones rest on some flat surface. The imitation of flowers is exceedingly perfect, and in this I noticed a decided improvement, the study of Nature having given place to a certain amount of mannerism that once prevailed.

The Ceterach was the only Fern I noticed about Florence, and that was very small.

From Florence we went to Bologna by rail. I wish my pen could give the very slightest idea of what those simple words include; never could I forget that railway journey! the awful precipices, the frightful chasms, over which we sped on our perilous way; now passing through the very heart of a great mountain, emerging from its side on a narrow pathway that seemed to tremble and quiver at our weight; again entering the Apennines by tunnels so close and long that the compressed air was like a great weight on the brain, and respiration became difficult; now shooting out on a frail wooden bridge spanning over a torrent rushing down far below; now gliding along the very face of a rock, so high that one recoiled from measuring the depth below; the glowing sunset giving the richest colouring to the scene, and after sunset came the moon, and then—Bologna.

Bologna is the very quaintest of all the quaint old towns of Italy. It has the gravest look of learning lurking about its heavy arcades and sober red-brick buildings; the leaning towers bend down towards each other, as if proposing problems in a whisper, and sober-coated ravens describe circles in the air, and everything in the old town has a wise and winking look, as if it had studied too much for its health.

At the Villa Reale on May 3rd I found the royal gardener putting out his bedding plants, which did not seem more forward than ours in England. I noticed but few young plants, the Geraniums were for the most part those of the last year much cut down; they had been kept during the winter in earth-pits, with very slight protection. The Orange trees were large for trees growing in tubs, and very healthy, but these, too, had been protected during the cold season. The gardener was, like all the Italians, most polite, he left us to wander about the garden and gather wild flowers as we liked, and on my admiring some brilliant *Ixia* (*Ixia crocata*), he immediately gave me a large potful, tying them up for me, flowers, leaves, and bulbs, in a tidy bundle, and telling me I need not touch them till I wanted them to plant in August. The peculiarity of the *Ixia crocata* is the transparency of the base of the corolla, which, when the sun was shining on them, gave the flowers the appearance of fire. In these gardens I gathered handsome specimens of the *Orchis pyramidalis* and the *Anemone hortensis* still in bloom. There was also a very fine *Petunia nycaginiflora* [?]. The white *Aracias* were in their first fresh bloom.

The picture-gallery of Bologna contains Raphael's *St. Cecilia*, some good *Francias*; but the gems are from Guido's masterly hand, his *Crucifixion*, *Sampson*, and *Murder of the Innocents* are magnificent compositions.—*FILIX-REMANA*.

MILDNESS OF THE SEASON.

THE day before Christmas-day I picked a very fine bloom of *Gloire de Dijon* Rose from a north wall, but on the last day of the year from the same tree I cut six or eight beautiful blooms, one or two being as exquisitely shaped as we should get them in May. Still further to show the mild character of the weather here, in Somersetshire, I saw on the 3rd of January two male specimens of the brimstone butterfly (*Gonepteryx rhamni*), flying about. I saw them in the same parish, but about a mile apart. I was completely astonished at the sight of the first, and he certainly was either astonished at me, or at finding there were no flowers and leaves. He did not appear to approve of the temperature, though the morning was sunny and bright, and he alighted on the ground, and I captured him, thinking it worth while to add to my cabinet a brimstone taken on the 3rd of January! I injured him rather in the catching, but otherwise he was a good specimen. The other did not settle,

but flew about very strongly, to the surprise of a woman to whom I pointed him out, and who evidently seemed to consider that something serious would happen. I am not aware that the brimstone butterfly hibernates, as the small tortoiseshell very frequently does—of the latter, I have seen five or six at a time in my saddle-room—if they do not, these must have emerged from their chrysalis state at a very early period of the year. I should be very glad to know whether they do hibernate.—*Y. B. A. Z.*

OUT-OF-DOOR STRAWBERRY RIPE IN JANUARY.—What a season we have had so far! On Saturday one of our men brought me a fully grown and nearly ripe Strawberry; strange for the 6th of January! I fear we shall suffer for it.—*J. R. PEARSON, Chilwell.*

PANISHING MOLES.

I HAVE in my charge a large Rose-bed, the Roses are on their own roots, and pegged down; lately moles have mined among them, lifting some of them nearly out of the ground. My employer is not willing that the depredators should be caught, as he considers they do good by destroying wire-worms. That, of course, I cannot deny, but the question is, Will the good done by them be sufficient to compensate for the injury they may do to the Roses? without taking into account the trouble of having continually to clear away the heaps of soil thrown up by them, and the untidy appearance they give to a place.—*C. C.*

[We have tried to drive moles away with bruised green Elder leaves, which you cannot, however, now obtain, and used bruised Laurel leaves in the runs of moles, with fair effect; and in the winter time we have opened the runs in different places, and poured in a little tar. Independently of the scent, they cannot endure anything filthy on their fur.]

GARDENING IN JAPAN.

My first visit to Yedo, soon after arriving in the country, being but short, and, owing to other circumstances, offering but limited opportunities for seeing the suburbs of the city, I was anxious to renew it, more particularly for the purpose of visiting the commercial gardens in the neighbourhood. By the courtesy of the Hon. Robert H. Pruyn, United States Minister, my wish has been gratified. Early on the morning of July 13th, in company with Mr. Putman, Secretary of Legation, and another visitor, I started for a twenty-mile ride on the Tokaido, to the great city.

The road, for the greater part of the way, presents the appearance of a continuous village. After passing the town of Kanagawa, the Rice fields are cultivated close to the margin of the road, extending like a green carpet to the rising ground, about a mile distant, and gradually coming nearer to it as you approach Yedo. Until you arrive at the river Logo, the spot of greatest interest is where Mr. Richardson was murdered two years ago. The road here, for the distance of about a mile, is bordered with Pine trees; and though of rather stunted growth, they give relief to the monotony of the dead level. Passing through the town of Kawasaki you arrive at the river, a stream of considerable length, and navigable for flat boats for a distance of about thirty miles. This river is the limit, toward Yedo, to which foreigners may ride by treaty stipulation; but, from the nervous state of feeling produced by several attacks on them when away from Yokohama, the privilege is not now often taken advantage of.

Here you dismount, and are ferried across to the other side in scows. The road from here, until you approach Sinagawa, a suburb of Yedo, is less closely built up than the part of the road just passed over. For two or three miles distance from the river the land is quite flat, yet not low enough for the cultivation of Rice. The soil is a light sandy loam, and well suited to the cultivation of vegetables. Occasionally, as you pass along, you see orchards of trained Pear trees, of the kinds peculiar to the country. The trees are planted, as nearly as I could judge, from 12 to 15 feet apart. After attaining the proper height, the tree is allowed to form branches, and these are trained to a rough framework of the same height, perfectly level, and extending over the whole area of the orchard. What object the cultivator has in training them in so careful a manner I have not as yet ascertained; but why may it not have its advantages in enabling him to secure his crops in the highest possible condition? Every fruit is thus brought into view, and within reach of the gatherer, who, where trees are left to grow in their natural form, too often

runs the risk, in order to secure some tempting prize, displaying its beauties on some inaccessible branch, or injuring the tree, or worse, possibly himself.

After crossing the river, we soon arrive at the famed Tea garden at Onura, celebrated for its Plum trees, so attractive when in flower. At the season we went up, they presented nothing more than Plum trees usually do.

The pains taken to bring every available space into cultivation for Rice, proves its value as the chief support of the people. Here and there in the fields spots of land are seen which, having been originally a little higher than the surrounding surface, and unsuited for Rice, have been levelled off, and are cultivated with vegetables. These dry spots are usually skirted with Pines, which apparently have been planted to prevent the soil from being washed away by heavy rains.

The country roads in and about Yedo are exceedingly pleasant, and generally sufficiently wide for two or three persons to ride abreast, and frequently for long distances are happily overshadowed by trees. Numerous patches of Bamboo are met with in every direction, and must be a source of considerable wealth to the country. It enters largely into the economic uses of the people, and for the purpose of hoops for pails and tubs of all sorts it takes the place of iron, hickory, and oak, used for the same purposes with us. The young and tender shoots in the spring are also in demand as an article of food.

To supply the wants of so large a city, the cultivation of vegetables is extensively carried on. The varieties, at the season of my visit, consisted chiefly of Beans, Onions, Egg-plants, Tomatoes, Carrots, Squashes, and Cucumbers. The manner of preparing them for market is exceedingly neat; everything being carried in baskets, they are brought in the best possible condition. The manner of cultivating the Cucumber was to me somewhat novel, and it appeared in some respects superior to our mode. Instead of sowing the seed in beds, it is sown in double rows, as Peas are frequently done, only at a greater distance apart, both between the rows and the plants, say 3 feet between the first. The vines are supported by placing brushwood along each row, forming an arch, over which they may grow. The advantage this method presents are, that the fruit is always clean and straight, of a uniform colour on all sides, and can be gathered without incurring the danger of injury to the vines by trampling on them.

The leaves of *Amaranthus melancholicus* are eaten as a vegetable, being boiled as a Spinach. A species of *Sagittaria* also appears to be used for the same purpose, as I observed, in one or two instances, small plantations of it in the corners of Rice fields. The large, fleshy roots of the *Nelumbium* are a staple article of food in the winter season.

One of the most attractive rides in Yedo, in which you see the chief business part of the city, is to the temple of Asakusa. In going there, the roads round the Tycoon's and Daime's residences are usually chosen, by which means you are enabled to have a good view of the moat and rampart that surround them. The space in which these residences are built, is an elevation of land considerably higher, in most parts, than the land immediately surrounding. The moat, which varies in width from 20 to 150 feet, has been dug at the base of this elevation, and is level with the streets on one side, but presents a high and steep bank on the other. In some places it is filled with *Nelumbium* and other aquatic plants, making, when in flower, a splendid show. The bank on the other side of the moat is covered with grass, nicely kept in order, with occasionally a few trees planted. The top is surmounted with a row of trees, mostly Pines, some of which have their branches extended downwards, relieving in a great degree the formality which such works usually present.

Surrounding the temple at Asakusa are extensive grounds, in which are included various shows, and places for practising archery. The most interesting part to me was that portion occupied by a florist's establishment. Here you find everything kept in the most order. The plants are arranged on elevated stages, divided with rolls of fine bamboo lined together, forming open mats, which can be rolled up when desired. They are much superior to a framework of lath, sometimes used by us for sheltering plants from the sun. The principal stock of plants consists of those most suited to Japanese tastes—viz., dwarfed Pines and Retinosporas, Sago Palms, variegated *Polecarpus*, *Andros*, *Sacchinellus*, &c., many of which are sold at what we would consider very high prices. I was surprised to find growing here three distinct varieties of *Veronica*, which I was not aware had been introduced, also *Jasminum grandiflorum*, and a species of *Franciscan*. With these exceptions, together with a dwarf variety of *Sago Palm*, there was nothing of especial interest

that I had not seen offered for sale in Yokohama. The grounds contained several species of trees unknown to me, which I would have purchased if I could have obtained small specimens. A pond full of scrub *Nelumbium*, the flowers standing on tall foot-stalks above the foliage, like immense Tulips, had a very fine effect. The Japanese gardeners cultivate a number of varieties of them having double flowers, and with various markings and shades of colour, some of which I hope to be fortunate enough to send home alive. The scrub *Chenodendron* is found to be a fine shrub, and here plants of it, grown in ornamental porcelain pots, made a fine show. The Japanese do not entertain our objections to growing plants in glazed pots; all the fine specimens are grown in them, and I certainly have not been able to see that they do not thrive equally as well as in any other kind.

One day we drove down to visit to the grounds at Danzozaki and Somena, two villages adjoining the city, where the outskirts of the city. We took an early start, and two friends and the usual escort of mounted officials escorted us to the train, and although we considered the latter somewhat unprofitable, the Government, under royal or imperial regard for our gratification, insisted on their attendance.

One side of the road which unites the two villages is bounded almost entirely with small nursery grounds. The one at Somena was larger than the one at Danzozaki, but at none of those visited did I see a finer collection of plants than at Asakusa. After visiting five or six, the guard became rather impatient, as I expected they would, at my frequent stoppages, and inquired what I wanted. I explained to them that I had a garden at home, and wanted to see, for the purpose of purchasing, what new plants I could find. As is often the case, they, not being interested, could not appreciate my motives, so, as it was already past noon, and very warm, with a long ride before us, I engaged to return if they would conduct us home as best as possible by some country road, instead of through the city. To this they assented, and conducted us back through a series of charming wooded roads and lanes lined with hedges on either side, and through the city within the walls, and most of the castle, when by we had a more extended view of that part of Yedo.

None of the gardens visited, or those seen on my ride, were very extensive, the largest containing but an acre or two of land; yet I am satisfied that there are large establishments somewhere in the neighbourhood, where trees are the principal objects of culture. I am impressed with this opinion from the quantities brought to Yokohama for ornamenting the gardens of foreign residents, and for sending away.

Another ride we took was to a celebrated tea-house on the other side of the river from Asakusa. This part of the city is intersected by numerous canals of great value for the easy transportation of heavy goods in a country where wheeled vehicles are of the rudest description. Above the city, almost as far as the eye can see, is one continuous Rice field, which in former years was an immense marsh, reclaimed from the overflow of the river by a wide dyke. The top, in most places planted with trees, constitutes the road along which you ride. The amount of labour employed to bring into cultivation the almost innumerable Rice fields all over the country is not to be estimated; but they are monuments of the toil of the people, and if neglected but for a few years, would become covered with a rank and noxious vegetation. Near the Tea garden we visited the residence of a retired merchant, who had the reputation of possessing a beautiful garden. In this I was disappointed, it being only of a larger size than ordinary, but presenting no remarkable features, either in style or its contents. Our disappointment in this respect was compensated by the kind hospitality of the aged proprietor and his family, who entertained us with tea and fruit, and did everything that Japanese courtesy demanded to render our visit agreeable.

One of the horticultural attractions of Yedo is the large *Wistaria* spoken of in Fortune's "Visit to Japan." Unfortunately, it was too late to see it in flower, but, judging from the still remaining flower-stems, it must present a rare object of beauty when in blossom. It is trained on a flat trellis over-spreading an area of more than 100 square feet.

In our rides about the city, we frequently met with horses laden with cut flowers, in which an extensive trade is carried on. The varieties are such as are most abundant at the particular season of the year, and just then consisted of *Chrysanthemums*, *Woblenbergiasinensis*, a species of *Artemisia*, and a few others.

In the rear of the legation residence in a small wood, in which are a number of large trees of *Torreya nucifera*. It is a very handsome species, growing to a height of 50 feet. If it prove hardy, it will be a valuable addition to our list of evergreens.

The large tree of Ginkgo biloba, preserved from the fire that burned down the buildings last year, still retained the attractions it had when seen on my first visit. When better known with us, the Ginkgo, as an ornamental tree, will meet with a more extended cultivation than it now receives.—T. HOGG.—(*American Gardener's Monthly*.)

PAINTING WOOD.

THE preservation of wood by paint is a matter of great importance to all who have glass houses. The best way of applying paint, as also the materials of which it is composed, are generally left to the painter, who is supposed to understand his own trade; the price of the work, the number of coats, and the colour to be employed, are generally matters of discussion; the quality of the ingredients is taken for granted. Are those wise who pay for a given surface to be painted without knowing what kind of paint is likely to be employed? From my own experience I think not. The majority of painters know little of the nature of pigments, and are as little able to judge of the quality of what they purchase as those who employ them. White paint ought to be carbonate of lead; what it often is it would be difficult to say. I have seen it rub off like a coat of whitewash.

But suppose we obtain really good paint, and oil of the best quality, we still are not safe. Something to cause the paint to dry quickly is almost a necessity, particularly for outside work, and the best paint may be spoiled. The protoxide of lead (discharge) is an excellent dryer for dark colours; the acetate of lead (sugar of lead) is equally good for light colours; but some stuff called patent dryers is generally used. What is this? Requiring no grinding, easily mixed, drying readily, it appears just what the painters want, but what is its effect? Have you ever seen an old oil painting cracked in all directions like a piece of seasoned pork? If you ask an artist the cause he will perhaps tell you "Oh that man's pictures all crack, he used too much varnish in his colours." Just the same effect is seen in almost all the common painting now. Ask the painter the reason, and he will tell you it is the sun on the varnish. Show him the paint is cracked down to the wood, and, therefore, it cannot be the varnish. Show him a door which faces the north, and, therefore, it cannot be the sun, and he will probably tell you he really cannot say what is the reason. My own opinion is these patent dryers are the cause, and the effect is in exact proportion to the amount used. Put a double or treble dose in your paint and see if it is not so. Whether I am right or wrong it may do good to call attention to the subject.—J. R. PLACON, *Chichester*.

LEGACY TO THE GARDENERS' REFORM BENEVOLENT INSTITUTION.—I beg to apprise you of the death of Mr. Henry Scott on the 5th inst. He was for very many years gardener to Wynn Esq., Esq., of Ponsbourne Park, Hereford. He was a subscriber to this Society since 1845, and, by his will, has left a legacy to this institution of £200. This is certainly a noble example, and needs no comment from me.—Edward R. CURRIE, *Secretary*.

COLLYER & ROBERTS' TOBACCO TISSUE.—This patented preparation for fumigating is used the same as tobacco or tobacco paper. Mr. Eyles says that "it is decidedly preferable to the paper in common use," and other head gardeners bear testimony to its efficacy as a destroyer of the thrips and green fly.

THE MODERN PEACH-PRUNER.—No. 20.

ORCHARD-HOUSE PRUNING AND TRAINING.

Bush trees in pots have apparently the advantage of being easy of formation; but, though readily kept in shape for a season or two after potting, they are apt to be thrown out of a true balance by any strong vertical shoot which may be overlooked. It is, therefore, on the whole, safer to induce the bush tree to assume some more regular shape, such as the pyramidal. In this case we may, by extra width at the base, cause the tree to look much like an ordinary bush, whilst we retain the advantage of having a main central stem from which the branches can be more symmetrically developed than if the tree divided into two or three strong branches at the

outset. By keeping the top of this low pyramid very little in advance, and allowing the base to extend freely beyond the pot, this form assumes an aspect different from the lofty pyramid with its comparatively slender base.

When, however, the bush form is retained, it is imperatively necessary to keep the centre open to the influences of sunshine and air. In this case, also, regularity of form is not only more pleasing to the eye, but conduces to the duration as well as to the productiveness of the tree. It is necessary, generally, to peg down the leading branches so as to induce the tree to form the U or goblet shape, and also to keep the branches at proper intervals by means of slender rods. One season of neglect is enough to spoil the whole appearance of any bush tree; indeed, it is rare we see any very handsome specimens after a certain age. Half-standards are much easier to keep in form.

Generally speaking, after a maiden tree has been headed down to six or seven buds (an odd number being preferable), the shoots proceeding from these buds should be trained carefully from the outset, and regularly stopped to equalise their growth. Should the tree not put forth a sufficient number of shoots, cut off the ends of those formed early in June, and from their points second growths will spring from which the requisite number can be selected to shape the tree. This is for ordinary bushes; possibly for U-shaped trees where the shoots are strong, it would be preferable to cut them back in May so as to induce them to fork lower down. The equalising of the whole form is to be continually attended to by stopping any shoot which protrudes. By cutting to a bud which points outwards the centre is kept more open in any case. Any laterals, later in the season, on the upper portions, can be slightly equalised as shown in No. 14.

At the October pruning the tree is formed according to the shape decided on. Goblet-shaped trees, with long vertically inclined shoots—i. e., branches in future, should have these left longer and not much shortened in. Perhaps one-fourth is sufficient, generally speaking, to suppress now. A few laterals may thus be retained within these dimensions, and these should be cut-in to two buds. Low pyramids will have to be cut back to a convenient group of triple buds, or to some single wood-bud looking outwards. Tall pyramids are treated in much the same way. The first winter-regulation is important for the beauty of the tree. In pyramids our greatest attention is needed to establish the lower portions from the commencement, and never to allow these to languish, nor to bear too early.

During the ensuing summer the side-shoots are to be stopped at three leaves, &c., as before directed in No. 18, for potted trees. If the summer-stopping of this, the second, season of the tree being in a pot, has been regularly done at the winter regulation, the tree will begin to assume a certain definite shape, and the pruner will be less puzzled than in dealing with more irregular forms.

It is always better to avoid cutting down potted trees, and rather to rest them for a season, by removing the fruit and re-modelling them. Whenever, however, a tree resists this care, it will be found that it suffers from some serious cause. The roots should be carefully examined, and if unhealthy the tree should be at once removed and another young one brought forward from the reserved stock. A few trees thus reserved will save much annoyance. Overcrowding is a fertile cause of the trees becoming shapeless and unproductive. In general, also, sufficient attention is not given to selecting handsome and regular shapes for potted trees.

The advice of some experienced person is of great use in the disposal of the trees in an orchard-house. The variety of forms and climates precludes any general rule in this matter, and, doubtless, we have all very much to learn in this respect. We have started from a good and tried basis, however, and may experimentalise without serious risk. The mere beginner, however, had better be cautious, and secure the soundest advice within his reach; at least, in such important points as the best shape and situation for his new house, and the selection and disposition of the trees within it.

If the summer stopping of the shoots be both easy to describe and to perform, the same cannot be said of the winter pruning. In this case there is no better way than to have recourse to our classification of the Peach shoots, and to state in what respect the winter pruning of each differs.

Peach trees in pots are stopped at three leaves, as soon as five are formed; and second growths at two leaves, as soon as three are formed; third growths generally to one more leaf, unless autumn growth be desirable to relieve the tree. (See

No. 18.) In the open air, however, the first summer stopping is made at four good leaves, as soon as six are developed; and second growths are stopped at two leaves, as soon as four more are grown. This gives us more fruit-buds and secure junction-buds, and also the triple groups below them. This is described in No. 17.

This style of stopping to four leaves is also the best for diagonal cordons on the back walls of orchard-houses when single and, therefore, at about 15 inches' interval. If planted at 12 inches' interval between the leaders being double or triple, then stopping to 3 inches may be advisable. Even then, in many cases, four leaves may be left with advantage, especially at the base. We have thus one single system of summer stopping adapted to orchard-houses, and to trees on the open wall. It will now be seen, also, that the winter regulation of the shoots can be conducted without any more distinction between house and open wall.

Recurring, then, to the classification of the shoots, it may be laid down as a fixed rule, that Classes 5, 6, and 7, should never be touched at the winter pruning. (See No. 9, Vol. VIII, p. 380.) Class 5, or the cluster-spur, is a perfect type, able to bear, and also to extend by means of its central leaf-bud. It is found in abundance on trees in pots, and on all kinds of cordons on walls. It is the mainstay of the close-pruning system. *Figs. 5, 20, and 21*, in support of this view, are photographed. On the shoots of diagonal-cordons of a certain age, this class is most common. In *fig. 22*, all marked *B*, are cluster-spurs, or "bouquets de Mai," as the French call them. Class 6, is the same spur after bearing. (See *fig. 6*, No. 9.) A little practice will enable the pruner to recognise it, and as it is short and has a terminal leaf-bud, it may be left untouched now, so as to make a new shoot during the summer. Of course, all below this growth will be done for ever, but this is not of much consequence, as is evident in *fig. 22*, where *c* shows its relative length and position. Class 7, or fruit-spray, is also a valuable type of shoot, very common in close pruning. In *fig. 7*, (No. 9), and in *fig. 22*, where it is marked *A*, we have examples of this class. In *fig. 20* (No. 18), it is also seen, the engraving being taken from a photograph; it has a terminal leaf-bud, and can bear, having single blossom-buds. If it had no wood-bud close to its base, it might not be so useful, but it generally has. Whenever, however, it occurs in the centre of bush trees in pots, it will then be found to be too long and liable to become straggling; in fact, too like Class 8. It may, but only in this case, be cut out, otherwise when it occurs in close pruning it should be retained as much as possible.

Class 8, *fig. 8*, page 380, is barren spray, or "chiffon," as Debonville calls it, an unsatisfactory class of shoot, which had better be suppressed whenever no gap is caused thereby. Bush trees in pots are frequently ruined by such shoots, and they indicate neglect of summer stopping, or weakness of the tree from want of air, &c. This type has single blossom-buds, but no terminal leaf-buds, hence its name.

Class 2, *fig. 2*, page 324, fruit-shoot of the ordinary character. In long pruning it is seen of almost any length; but in close pruning the beautiful shoot shown in *fig. 21* is what we should prefer to see. In this case, being only about from 4 to 6 inches in length, we may allow it to remain untouched at the winter pruning, and cut it close in to the one or two wood-buds seen at its base, after it has produced fruit. When longer it then becomes useful to form a new branch, and thus easier to have

the distinctive character of the shoot seen in *fig. 21*. Class 3, or the mixed shoot, is also common in young trees, and useful to shape them. Whenever, then, either of these types occur as extensions of any form of tree, they should not be shortened after the first year or so. In close pruning we can cease to think of them as shoots, and rather incline to regard them as useful to bear the shorter one only.

Class 4, *fig. 4*, page 324, Pure Wood-shoot. Naturally inclined to grow low, and having a few feeble flower-buds at its extremity. Seen in young trees, and also on the extensions of older forms, and only useful in this respect, in laying the foundation of taper wood.

Class 4, *fig. 4*, page 325, the Cross Shoot, or "Command" of the French. A vigorous development of Class 4. Useful to form young trees quickly, but to be carefully watched in older forms, lest the tree be thrown out of balance. As the main stem of a healthy pyramid in the border, or in the case of a fan-shaped tree on the wall, where it is preferred not to divide the tree into two wings, much progress is made by it. It is readily known by its darkened or "blackened" leaf-buds, and the prominent lateral thorns, but the upper portions. In close pruning, however, all these naturally long shoots become, practically, only useful to form the tree, while the naturally shorter shoots are retained to bear the fruit. By allowing the longest to remain at full length after the first or second season, and by the close summer stopping of the shoots,

we increase this distinctive character, and thus return to first principles.

Although more regular forms are desirable, there is no reason why irregular fan-shaped trees should not bear well when closely pruned. In some cases this form may be even the best adapted, and, no doubt, much advantage is gained by having a biennial supply of young and healthy wood. Gaps made by unskilful pruners may thus be filled up. *Fig. 22*, however, clearly shows how it is possible to have regularly disposed branches, and, at

Fig. 22.

the same time, to preserve the spurs on them for many seasons without recourse to amputations or fresh wood. In this specimen, drawn from nature from a diagonal cordon about ten years old it is evident that the double spur is as old as the parent tree, and this without being more than a few inches in length or half an inch in diameter. The left spur bears the marks of numerous suppressions of former shoots. It retains two of these three or four seasons old, and only respectively 1 inch and 2 inches long. On the upper one are the cluster spur *b* and the fruit spray *A*; on the lower one is another cluster *n*, and this same type after bearing, *c*. Springing from the very base is a pure wood shoot *n*, which has been cut back to two wood-buds to form succession shoots. The spur on the right is not so thick as its fellow, but also shows marks of work. It bears three fruit sprays *A* and four cluster spurs *n*. Also at its base we find a shoot having groups of triple buds (class 2), and cut back above the lowest of these groups. This shoot is cut back for the same purpose as that marked *n*, and is itself marked *n*. It is, therefore, quite evident that the whole of the two aged spurs might be cut off after bearing, leaving some four or five new shoots springing from *b* and *n*. These spurs and their beautiful fruit-bearing shoots thus seen, are really a triumph of close pruning. No one can reasonably doubt that there is a promise of abundant fruit here, lying close to the wall, and produced by a type allowed to be that which bears the very largest Peaches. It would not be at all

necessary to remove these fine old spurs, as the shoots on them will not become very long for some time, so that the "modern close pruner" is never embarrassed by any want of material to select from. His great aim must be to endeavour to prune the shoots on the "alternate system," seen in *figs.* 18 and 19, which, duly attended to, will, after many seasons, produce specimens resembling *fig.* 22.

It remains only to add that *fig.* 23 represents the plan of

formation of a wall of diagonal cordons. As my good friend Mr. Rivers has lately erected a house which he justly estimates as likely, from its immense proposed length and novelty of design, to prove "one of the sights of Europe," and, as the back wall of this house is devoted to diagonal cordons, perhaps this design may be useful. A Represents the angle of a diagonal cordon against the wall. It might be even lower. B Would be a single cordon without the addition of the leader *n*, which will

FIG. 23.

make it a double diagonal cordon. *c* Is a short branch to fill up an interval; not very necessary, nor very productive. *d* Is an upright cordon from which leaders are taken to fill up the wall space at one end, while *n* shows how the other end should be finished. If the horizontal portion of *n* were first well established, the leaders could be readily developed from it. It is also of importance in forming the double or triple cordon to keep back the second leader about half way the length of the first, otherwise the second leader would, from its vertical posi-

tion, absorb too much sap; in other words, establish the first leader well before the others are formed.

The late and lamented Dr. Lindley, in reviewing cordon training, objected to the sharp angle made at *n*, as shown in the frontispiece of that work. It is now remedied; but in actual practice it never was so severe. Otherwise, he thought well of this system, and it is now presented under an improved aspect, the result of five more seasons of experience.—T. C. BRIDGEMAN.

WORK FOR THE WEEK.

KITCHEN GARDEN.

LITTLE out-door work can now be done where snow has fallen, and we believe this to be the case pretty generally. As this will be a leisure time, apply it in making preparations for the forthcoming spring. Let plenty of pot-herbs be broken of different sizes, prepare stakes of all kinds and paint them, see that all the pots are perfectly clean and in a dry shed, and employ the men about such work as can be done within-doors, and which we have already pointed out. Carrots, as soon as the young plants in the hotbed are about an inch high, thin them out to 3 or 4 inches apart. Radishes are sometimes sown in the same bed; when this is the case they should also be thinned, and, when ready for use, they must be drawn with care, so as not to injure the tops of the Carrots. *Coultiflowers*, should the weather prove severe, the frames containing young plants should be covered with mats, or some material, to protect them; plants in the open ground should have some pliable rods bent over them, and then covered with mats. Cucumbers, as soon as the young plants have perfected their seed leaves, they should be potted, two in a pot, about 4 inches in diameter, using some of the soil already in the frame; plant them deep in the pot, so that a little fresh soil can be added as they grow.

The fruiting-bed should now be made; after the heat is up stir the dung inside the frame every other morning until the heat is sweet and regular. *Kidney Beans*, the plants in bearing should be placed in saucers or shallow troughs having some soil in them, which should always be kept moist; this will encourage the growth of roots, and will also prevent the heat of the fire or pipes drying the soil at the bottom of the pots. *Lettuce*, protect the frames which contain young plants for spring use, when the frost is severe; those which contain Cabbage Lettuce for present use must also be covered up. *Mushrooms*, beds should now be made in sheds or houses purposely fitted up for a spring supply. The horse-droppings should be well beaten down, and the bed should not be less than a foot in depth. Temperature-sticks should then be thrust to the bottom in several places and examined daily; when the heat has become somewhat regular, and not exceeding 80°, the spawn may be inserted just below the surface, and the bed afterwards earthed up. *Strawberries*, a few dozen pots may be placed in a frame where there is a gentle heat, the frame being so much more congenial to their growth than the atmosphere of a house. Continue, as occasion may require, to cover a portion of *Sea-kale*. *Rhubarb* may also be forced in a similar manner.

FRUIT GARDEN.

Some recommend deferring the pruning of Peach, Nectarine, and Apricot trees till late in spring, or, at all events, till the period when severe frosts are not likely to occur. It is certain that by late pruning the force of vegetation may be considerably weakened. The French recommend it for trees that are over-luxuriant, but it is much better to effect this object by a reduction of the foliage of the over-luxuriant portions, whilst the weaker are allowed to retain all their foliage, for, by this means, the weak are encouraged and the strong checked, i.e., balancing the force of vegetation throughout. Late pruning weakens the whole, the side branches as much as the upright; it does not tend to produce the equilibrium so desirable, and therefore must be considered objectionable. The only question, then, is, Whether it may be best to prune now, and ensure the buds pushing boldly, supposing no severe frost should occur, or defer pruning, in case the weather should prove injuriously severe. In the one case the advantages are great and certain, whilst the injury that even severe frost occasions to well-ripened wood is trifling; besides, if such frost should occur, a slight protection will be sufficient. In pruning Gooseberry and Currant bushes let the centre of the bushes be kept open and free, and cut out all branches that cross one another, leaving the leading shoots about 10 inches apart, and topping at a bud inclining to the open space. All lateral twigs not required to form branches, should be spurred in to a few eyes. The fruit is to be on short natural spurs, or on clusters of buds formed on the old wood itself, and also on young shoots, which should be shortened to one-third of their length. Old wren-bush bushes to be cut back to a well-placed shoot.

FLOWER GARDEN.

The weather having changed to snow, leave off digging borders for a time, particularly when the soil is of a stiff nature. When snow has fallen it may be necessary to look round the shrubberies and remove any of the trees and shrubs of their bark, where they are likely to sustain any injury. Secure all plants from frost that are likely to be injured by it.

GREENHOUSE AND CONSERVATORY.

A day temperature of 55° will be quite sufficient here at present; if it cannot be maintained without strong fires, be content with 45° and moderate fires, remembering that with this low temperature a very small circulation or motion in the air will suffice. A higher degree of heat would both hurry the beautiful *Convolvulus* and other choice flowers past their best, and also create a necessity for the application of more atmospheric moisture, which, unless a warm roof is secured by covering, must end in drip, to the great prejudice of the delicate flowers. Those who possess only one small greenhouse, and are desirous of a variety of early flowers, may now introduce from the cold frame or pit a few of the early Dutch bulbs, provided their pots are full of roots, without which the application of heat is vain. They should be kept in the darkest part of the house, or what will be more congenial to their habits, covered over and with a mound of soil. The two points are easily accomplished by first piling up a mound (moss would do), and then inverting a pot over the whole. The continued damp atmosphere which has prevailed for some time, especially about London, has caused great destruction amongst many soft-wooded plants; they should be carefully examined individually, and every infected leaf or branch removed. Occasional slight fires must be applied, but this should be carefully and judiciously done, or the cure will be as bad as, if not worse than, the disease. The injury greenhouse plants suffer from overheating is at least equal to that from frost.

STOVE.

Examine the various tubers and bulbs that are dormant, and see that they are in a proper condition, neither suffering from wet nor mouldiness. *Achimenes* and similar plants will soon require to be watered; there is little to be gained, however, by commencing before the season. When heat is applied to start them during winter, the shoots are of necessity drawn and etiolated. It is at all times better to do things well in good season, for it is scarcely possible to do them well at a bad time. The art in this department at the present season is to prevent plants from growing.

FORCING-PIT.

The tank forcing-pit may be made everything that can be desired wherever there is a regular provision for bottom and atmospheric heat from a fire; but it is not so with the dung forcing-pit in the dead of winter. The following plants may now be introduced with every prospect of success, the plants being in

good order:—*Gardenias*, *Hedychiums*, *Grisebans*, *Daphne encorrum*, *Clorodendrons*, *Cytisus*, *Honey-suckles*, *Sweet Peas*, *Roses*, *Lilacs*, *Rhododendrons*, *Azaleas*, *Kalmias*, forcing *Pinks*, especially the *Anne Boleyn*, *Abies*, *Chrysanthums*, *Hydrangeas*, and *Heliotropes*. It is not meant that the above are equally eligible for forcing, but that any or all of them may be attempted if well prepared for the purpose in the previous manner, by early growth, early rest, and a potful of healthy roots. With such a miscellaneous mixture it is evident that root-tronics of atmospheric management should be provided, the amount of moisture which the *Gardenias*, for instance, will revel in would prove prejudicial, if not destructive, to such plants as the *Heliotropes*.

PLANTS AND FRUIT.

Should the lights become green from damp or other causes, take advantage of favourable weather and have them washed, it helps to strengthen the plants at the dull season by admitting more light. Surface-dress the pots and pick off all damp leaves. Place in heat *Lobelia fulgens*, *Chelidonium majus*, &c., for potting off in February; they do much better treated in this way than potted off earlier, as the young roots, having been excited, take at once to the soil. *Calceolarias* which were put in last October are now ready to pot off; therefore do this at once with such as are rooted, and should there be any that are not, place them in a gentle bottom heat. All new kinds of *Viburnums*, where the stock is short, should be cut for cuttings.—W. KILPATRICK.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

See last week as to vegetables in general, and Sea-kale, Rhubarb, and Asparagus, in particular. Had a nice frost on Tuesday morning, which enabled us to have some dung wheeled from old hotbeds to borders and quarters, now soaked with winter stuff, but which ere long must go to the loss soon. What storms of wind and hail on Monday and Tuesday! On the afternoon of the latter day, though the wind was westerly and the barometer low, the sky was so clear and sharp, that we had to get everything we could in the way of litter or protection; but it was next to a false alarm. However, it is of no use to shut and double-lock the stables or when the stock is stolen. As an act of retaliation, a lot of *Camille* worms, &c., we did not uncover on Wednesday, though after breakfast we were unable to wheel without making a mess, and therefore, took to other work. One secret every gardener should aim at possessing, and that is, the knowledge how to do work without making work. Of course there are occasions when a job must be finished whatever the weather is; but much available labour will be turned to the best account when the work is proportioned to the weather.

Mushrooms.—For fear of frost put in a little litter over the bed in the open shed, and which is still producing, but more sparingly now. The first bed in the Mushroom-house on a shallow shed having produced heavily, and shown signs of decline, though many *Mushrooms* are coming as pin-points, the surface being a little rough by twisting of the crop, we watered the two or three down on the larger *Mushrooms*, stuck the stall in dampness to keep for a day or two, as by that time the others will be large enough, and swept the bed nicely all over with a hand hair broom, so as to leave the surface smooth and hard again; and as the bed seemed moist enough, just sprinkled a little dry hay over it, and put two or three barrwheels of hot dung in what some day will be the ground bed, below this platform one. Judging from what generally takes place, in about ten days, when the *Mushrooms* that are buttons now are gone, the bed will be pretty well covered in good condition by those now scarcely larger than pin-points. This slight sprinkling of hay over the surface of the bed will keep the bed more equal in heat and moisture, than making the house hotter would do, and then the fuel also is saved.

Lest some should think we are wasteful with our hay, we may mention how we obtain it. On parts of the lawn at a distance from the house, and where a number of evergreens grow, we do not cut the grass until it is of a good length. So many leaves of evergreens, and bits of twigs, render it unfit for hay for cattle, but when nicely made and placed in a little rick it becomes useful for all such purposes, and also for covering up plants under glass, in frames and pits, in very severe weather. We keep this as a reserve-heap as long as we can. One year, after we had placed our *Geraniums* for beds,

under mats, calico, and frames of straw made so thin as to let light enough through them, we would have lost most of our plants by a severe frost in the end of April, if we had not possessed a piece of this rough stuff to go to and shake gently all over them. We shall never forget Mr. James Barnes, of Bicton, saying in one of his pithy papers, "A few hours will sometimes destroy the preparations of a season, and the mortifying thing then would be, that the sun would shine as brightly, and the grass would grow as green, and the birds would sing as merrily, as if there had never been that cruel frost that made such havoc in a few hours as to pretty well embitter for you all the pleasing events of the season."

Our second piece in the Mushroom-house, say 13 inches deep at back and 10 inches in front, that was spawned nearly seven weeks ago, is now beginning to have white places on the surface, in which the incipient Mushrooms can just be perceived. In this bed there is also a sprinkling of the rough hay, and in these cold days when we put the hand on the surface of the bed, there is just that nice gentle warmth that tells us the spawn is working away kindly. The third piece is spawned and earthed up, and going on all right, and the fourth piece has the dung beaten down; and as it had been dried a little and thrown into a heap in a shed before bringing it on, there has been no trouble with an extra moist atmosphere as there was at first, and to counteract which we used mats suspended over the first bed, as detailed some time ago. Our practical friends will excuse these simple details, as some who are beginners fail because they neglect simple matters. From circumstances we could not make a large bed if we wished, and we have become so used to these small beds, and having them in succession, that we do not think we would care to change if we could. Good Mushrooms, valuable at all times, are particularly so in winter, and are easier grown than they are in summer. One word let us add for the benefit of amateurs who try to grow them in empty stalls of stables, byres, &c., and that is, when the weather becomes cold, just add a little more covering over the bed, and lessen it when it is milder. Always bear in mind that an excess of heat is more dangerous than cold. The spawn will stand much cold, if not run out with too much wet. The bed should never be hotter than the hand, when that hand is as warm out side as the blood is inside. The surface of the bed, before the Mushrooms come through, may feel a little warm—about 70°, but, as soon as safely through they will be better if the temperature is from 55° to 60°; but much lower would do, provided the bed was not too much cooled. We are glad to find that some are growing Mushrooms in large pots. We like boxes better, because the wood secures a more equable temperature, but either will do. One advantage of the pots is, that if the material become too cold to produce Mushrooms freely, the pot may be placed in a heap of fermenting material so as to raise the temperature to from 70° to 75°, but taking care that the surface be not continued at that heat.

Asparagus.—Had the beds and single rows and ridges, where the buds were near the surface, covered with half-rotted dung and tree leaves from spent hotbeds, which will make them all secure from the frost, and help to nourish them besides. We will throw a lot of burnt rubbish and clay over this when we can, which, from the vegetable rubbish contained, will act very much in the way of a salt-dressing. Top-dressing Asparagus we consider of more importance than placing manure at great depths, and did we not want the short cuttings from the lawn for other purposes, we would give a fair portion of them to Asparagus-beds.

As it happened, we need not have troubled ourselves as to frost at present, for during the night there has been, what has been expected, a heavy fall of snow, measuring 8 inches deep in open places, this Thursday morning, and the snow still falling heavily. The first part of the winter has resembled that of 1860-61, and if there should now be an approach to that season, the snow if it remain some time will be a great protection, though it will hinder out-door work.

Kidney Beans sown in four and five-inch pots have been transferred in a piece into nine-inch pots, using rich light soil that had been warmed. This plan is, perhaps, better than sowing in boxes and then transplanting, as that always gives a little check. After this season we prefer sowing in pots, or boxes, where they are to produce, filling the pots three-parts full, and placing about five Beans in a pot; but this requires a good deal of room at first, one pot occupying the space of a number of small ones, and the small ones answering equally well until the stems begin to run.

Cucumbers in rather large pots placed about the middle of a

small pit that they might have more light in this dull weather. Cucumbers and Melons may now be sown where there is a suitable heat, but we always think that young Melons do best when raised in a hotbed, though they be transferred afterwards to beds heated by hot water or flues.

FRUIT GARDEN.

Strawberries in pots are just beginning to move. Those set on very slight hotbeds, as detailed lately, are also moving, and when the weather changes we shall take them into the Peach-house, where, as lately stated, we have lighted the fires, and there are signs of movement; the temperature from fire heat is from 45° to 50°, but seldom up to the latter figure as yet, with air early and a rise from sunshine when we can. Cut most of the late Grapes to hang up, so as to have the house cleaned in this stormy weather; washing glass, woodwork, Vines, stages, &c., with soap water, syringing all with warm water, taking away a little of the surface earth of the floor, so that all shall be clean and nice. Few things look worse than the glass of houses dirty and covered with green slime, and strings of fungous matter suspended from the sash-bars and walls as if these had long been strangers to linewash. Washed the walls well before colouring them afresh. These little precautions do much to keep away shoals of insects. This house we shall fill with plants directly, and they will remain there until the buds break naturally. We generally bring all the Vine-stems to the front of the house until the buds all break, because they are thus out of the way, and break more regularly from being for the whole length in a similar temperature. Last season they were suspended under the roof about 2 feet or more from the glass, and in that position also they broke pretty regularly. This last plan involves less trouble afterwards, but for early forcing we prefer the first mode.

Orchard-house.—Fortunately we have a heap of Laurel twigs that had been used as creosote vents, and as the roofs of these houses are now covered with snow, we shall burn a lot of these shoots, and have two or three fires in each house to fill it with smoke from the e-brained leaves, &c., taking care so to cover each fire heap with moss, that no flame shall issue. This Laurel smoke will find its way into every hole and cranny, and kill every thing that is alive. We shall do this by way of precaution, for though no insects have shown themselves, still there may be some, and the smoking will cost nothing but the labour. The paint and the wood of the trees should be dry before such smoking. If the wood and paint are wet the paint will assume a dark colour, from a penicillate of lead, but even that will wear off if let alone long enough. The less lead there is in the paint the less will it be affected by such smoking, even if the paint be wet.

ORNAMENTAL DEPARTMENT.

As soon as the men can stand out, the walks and thoroughfares must be cleared, and many shrubs saved of the weight of the snow, which otherwise would bend them down and break them. All plants in cold frames and pits, from having had plenty of air, and being kept very cool, and shut-up cool, will have no uncovering whilst the snow-storm lasts, unless it remain a very long time. There is no better protecting medium than the snow, and why should we remove it? As soon as the snow begins to melt, however, it should be removed, and cleared away from the sides, so that the moisture may not soak down and rise again among the plants inside.

We have frequently stated that where there is nothing but *Cold Frames and Pits* for keeping bedding and other half-hardy plants, instead of going down in a pit to obtain heat, it is better to go up for dryness. We have lately done little in this way ourselves, but we have previously proved the advantage of it. Let the platform for the frame or pit be some 6 or 9 inches above the surrounding soil, have a sloping platform all round some 4 feet in width, and the outside of that at least 6 inches below the frame platform, and cover this outside platform with a coating of tar, and then with gravel. According to the thickness of the gravel you must sink the surrounding walk more, and this will carry off the water. If it could be done in summer we would coat the ground inside the frame or pit with tar and gravel in the same way, the smell would be all gone before autumn; and then a layer of dry rough ashes for setting the pots on, and great care in watering, taking out the plants that are dry, and watering them outside, would prevent much damp in such places in winter. We keep a good many plants under frames raised over hotbeds in spring and summer, just where these stood, but though we place a board in front or a rough spout to prevent the water that runs off the glass falling

of the frame, and, and the air penetrating into the bed, and the heat of the plants, but of more time will rise not with the heat of the little ones. The only advantage of using the frames of which I have spoken, is that if the plants are rather crowded in the autumn, I place a layer of dry leaves round them, and give them a little cover, so that if the frost is severe in the autumn, frames of the same size will contain more before the autumn, frames of the same size will give a considerably more time, and rise up from 10 to 15 degrees of heat from the heaven will rise away, and let any wind from the sloping ground round them, and frame.

If the gardener wishes for double sashes, the plants in which are not artificial heat, we would not. For the double sashes do not sink it at all, but it is soon after the autumn, let the heat be 6 inches above the ground, and let the ground 1 pe. out, and cover the top by ground and the outside ground with a string of turf, from one foot to one and a half inch, and give it with an inch of rough gravel, and when the winter comes, through adding more gravel, finer, dry, and rain, and perhaps a sand, and all will be hard and snowy, and before the end of summer. We would also paint the inside of the wall with turpentine lamp, and water as above mentioned. The frame-watering base lies a little below the level of the floor to let out water when you may use it if needed. The top layer of earth, built of straw, on the wall, in autumn, and the chief one necessary to be kept first from water, and the wall, and for that waterproofing, being in fact, with enough of litter or dry material to keep at the feet. Frames could be set down and the sides covered with straw in the same way. On the whole the straw is the best and the best, and keeps out frost without heating the wall at all. Where it is not in summer is no great object, the straw may remain. We have had it thus tried on a 12 remaining pretty neat and available for three years. We are the more particular as to this because we have seen plants a mass of rotteness from frost, in frames and pits, where ample protection had been used over the glass; but in the case, through the wall or the boards, at the sides. As to protection for the glass, the best and cheapest is the ordinary wooden covers or shutters, made to fit the sashes, and of good half-inch or three-quarter-inch deal well braced beneath. The next best, perhaps, is asphalt, supported by a frame, made of the stout sash; but two persons are required to take off and put on such covers. The next would be light waterproofed material, which could be rolled along and secured back and front with strings. We need not speak of straw frames, mats, &c., all are good enough when better cannot be had.

Though we have spoken of letting our cold pits and frames remain covered up in such weather, this must not long be the case, when artificial heat is given. Where that heat is supplied, and the light possible, though so heat can be obtained in a dull or snowy day, must be given, and though in such a day, if this we will not uncover, still it would not do to let them remain very long in darkness. We have had frames and pits with *Calceolarias*, *Verbenas*, &c., shut up in severe weather for six or seven weeks, and when gradually exposed to light they were looking little different from what they would have done with the darkness of only one night; but they did not grow or lengthen all the time, as the temperature inside would not average more than from 33° to 37°. The late Mr. Errington used to let his *Campanulas* under hand-lights be slightly frosted before an expected continuance of frost, and then he protected the glasses with litter to keep more frost from entering, and so long as the frost continued the litter remained. There could be no growth in the *Campanulas*, and, therefore, no danger from the continued darkness, and this darkness in such circumstances was less injurious to the plants than being exposed to a piercing dry air and even a bright sky during the day, and a covering up every night.

We would submit these remarks, and what was said last week about propagating heat to light, to all beginners, as they will equally apply to greenhouses and plant-stoves, forcing-houses, forcing-pits, &c. The great point in such weather is to keep the plants safe, so as to check, but the heat still low enough not to encourage much elongation of the shoots. Mercuries in houses may range from 40° to 45°; conservatories, according to the plants in bloom, from 45° to 50°; plant-stoves from 55° to 60°; forcing-pits may have a bottom heat of from 70° to 80°, and a top heat of from 55° to 60°, or a little more if there should be more light. If more may be added, with air given early, however little; if very cold, enough may come

into open house through the top of the glass; if the weather should be severe, give only a little at the highest part of the house, and let the fire be means for heating and moistening the air before it has its way among the plants. As a rule, as little water as possible should be used; but if the frost should turn out severe, and even for these comparatively low temperatures a good deal of heat should be poured, belonging to the floors and stones, carefully with the syringe will be better than giving too much water to the plants. In frosty weather, and in a sunny day, it is better to let the house rise 10° or 15° above the temperatures just stated, in preference to giving outside to increase of dry pushing air. A little air given early will prevent any necessity for this. Be assured that strong fires at night, and even during the day, and sashes rammed down in great spaces, when the sun is powerful, are like a waste of fuel and an injury to the plants in very cold weather. If sun is a point it is better that the fires should go out, than that a great mass of air should be given under such circumstances.

Such a winter furnishes a good opportunity for forwarding home a variety of plants and fruit trees, examining Potatoes, Dahlia, and Begonias, stopping and tying to manure, pruning and painting. Each is, perhaps, an outline of whatever is scarce, or a fine pots with forced water, and some sheds, making tallies, and planting stakes, &c. G. F.

COVENT GARDEN MARKET—JANUARY 15.

Some frost in the evening of the various Winter Greens this season, but the late inclement weather has but slightly influenced our markets. The foreign trade has, however, been much interrupted. Apples and pears are comparatively scarce. Dessert Pears consist of *Clon*, *M. de St. Pierre*, *Beurré*, *du Rameau*, and *Ester Beurré*. Potatoes are much supplied.

TO CORRESPONDENTS.

STELIO, GRAPES, *J. Rogers*.—Written to Messrs. Webber & Co., fruiterers, Covent Garden Market.

COVENT GARDEN, *H. F. A.*.—We never heard of moulds for making "earth pits," and do not even know what they are.

CAMELLIA CULTURE (*One of Your Very First Subscribers*).—If your plants are pot-bound, or, for their size, in very small pots, and do not appear to have been shifted for a number of years, then repot them; but, if they have been recently potted, and the soil and drainage are good, you had better let them remain as they are, especially as you propose cutting them in. If you pot the plants, turn them out carefully, remove the drainage, and pick out the old soil from amongst the roots, being very careful not to break the fibres, which are extremely brittle. Use any size of pot that will allow of half an inch of fresh soil being placed around the ball, and working the soil so as to leave no vacant space between the ball and the sides of the pot, and let the collar be slightly elevated in the centre of the pot. Drain the pots well; one-fourth their depth is not too much. Use none but clean pots, well-washed inside as well as outside, and let the compost consist of two-thirds sandy turfy peat (not log soil) or the mossy brown peat used for growing Orchids, and one-third turfy loam, rather strong, but not heavy—that from rotted turves a year old is best, the whole broken; and chopped with a spade, and made pretty fine, but not sifted, adding one-sixth of silver sand if the soil is not sandy enough. The end of March or early in April is a good time to pot them, or about a fortnight after the bloom is over. About the middle of April the plants may be cut-in, and this you may do to any extent; but it is better to give them both on heat afterwards in order to induce them to break well, and such encouragement would be especially useful in your case if they are fresh-potted. A bottom heat of 75° for six weeks would be of great service in inducing them to break, especially if you cut them in much. Towards the end of April maintain a temperature of 50° at night, in a fortnight increase the temperature to 55°, and in the course of another fortnight to 60°, with a rise by day of 5° in dull weather, 10° when cloudy with clear intervals, and from 15° to 20° with sun and a cloudless sky. Give air on all favourable occasions. Sprinkle the paths, floors, and every available surface twice daily, morning and evening, with water of the same temperature as the house, and syringe the plants overhead morning and evening, until the young shoots are a few inches long, then discontinue the morning syringing, giving air early so as to have the leaves dry before the sun shines fully upon them. When the shoots have done growing, gradually discontinue fire heat, and give all the air possible, decreasing the amount of moisture, but still sprinkling the paths, &c., twice daily. As you have the option, do not turn the plants out of the house, but keep them as cool as possible by admitting day and night as much air as possible.

PLANTS FOR ROCKWORK (*Old Deer*).—On the shady parts of your rockwork you may grow the following Ferns, watering them copiously during dry weather when growing. *Asplenium adnigrum-nigrum*, *A. viride*, and *A. trichomanes*; *Allosorus crispus*, *Elaeagnum spicatum*, and its varieties *crispatum* and *ramosum*; *Lastrea obovata*, *L. Filix-venus*, and its varieties *crispata* and *Schottii*, *L. rigida*, *L. dilatata*, *L. Fenisecii*, and *L. cristata*; *Osmunda regalis*, *Polypodium vulgare*, *P. phegopteris*, *P. dryopteris*, *P. aspretrix*, *Polytichum aculeatum*, *P. lobatum*, *P. angulare*, and its variety *proiferum*; *Scopolopodium vulgare*, and its varieties *indivisi-folium*, *multifidum*, and *ramosum*; *Cystopteris Dickiana*, *C. fragilis*, and variety *dentata*; *Athyrium Filix-foemina*, varieties *apiculata*, *depauperata*, and *plumosum*; *Oenoclea sensibilis*; *Osmunda cinnamomea*, *O. interrupta*; *Strathiopteris germanica*, and *pennsylvanica*; *Polystichum acrostichoides*, *P. proliferum*, and *P. pungens*. Of hardy Heaths for the sunny parts—*Erica vulgaris* *Alporti*, *alba*, *Hammondi*, and *rigida*; *E. cinerea*, varieties *alba* and *coerulea*; *E. vagans*, varieties *alba*, *carnea*, and *rubra*; *E. scoparia*, *E. tetralix*, *E. hercynica*, and variety *carnea*; and *E. ciliaris*, *Ornithoglossum*; *Arabis alba*, and *alpina*; *Austriaca deltoidea*; *Lotus corniculatus* *flor. pleno*; *Theris sempervirens*, and *saxatilis*; *Genista triquetra*, *Dryas Drummondii*, *Draba aizoides*, *Alyssum saxatile*, *Saxifraga affinis*, *Aizoon*, *Bucklandii*, *oppositifolia*, and *petita*; *Dianthus alpinus*, *D. deltoidea*, *D. floribundus*, and *D. erucatus*; *Cerastium Biebersteinii*, and *C. tomentosum*; *Sedum Ewersi*, *S. album*, *S. kamtschaticum*, *S. Sieboldii*, and *S. rupestris*; *Stachys lanata*; *Silene alpestris*; *Senecio alpestris*; *Scutellaria alpina*; *Cochlearia grandifolia*; *Armeria vulgaris* *alba*; *Alchemilla alpina*; *Ajuga reptans variegata*, and *Cheiranthus alpinus*. The Ferns are for the shady, and the Heaths and following plants for the sunny situations.

PROPAGATING MRS. POLLOCK GERANIUM (*A Constant Reader*).—You will hardly be able to obtain cuttings from your autumn-struck plants before the middle of February, even if you keep these in a temperature of from 45° to 50° from fire heat, which is sufficient forcing. The tops of the plants may then be taken off, and made into cuttings. They will soon root in a mild hotbed of 72°. The plants being repotted, plunge the pots in a bottom heat of 75°, with a top heat not exceeding 55° from fire heat, and in six weeks you may be able to obtain another batch of cuttings. Under this treatment you will obtain a quantity of small plants, which will not afford anything like the same degree of satisfaction that one-half or one-fourth of the number of well-grown plants would give. Plants of this Geranium require to be strong and well-hardened off before planting out.

GRAPES REMAINING ON THE VINE (*J. C.*).—However long they may be allowed to remain, they will have no injurious effect on the crops of next season.

DRACENA FERREA AND PALMS IN A DRAWING-ROOM (*E. D.*).—The cause of the leaves being spotted is their being constantly syringed whilst the soil is kept constantly moist by too frequent waterings. Water only when the soil becomes dry, and only syringe occasionally to free the leaves of dust. Such plants, though retaining their beauty in rooms for a long time, cannot be grown there, and should therefore be returned in good time to the stove, in order to perfect their growth.

CRYSTALLISING FLOWERS (*Ethen*).—We have no experience of this practice, nor did we ever see flowers so treated. The following, extracted from an American paper, may aid you:—“CRYSTALLISING FLOWERS.—It is done by suspending or repeatedly dipping them in water saturated with alum. This, however, can only be done with dried specimens. The freshness and beauty of flowers can be preserved by dipping them in glycerine.”

CONSERVATORIES AT KEW AND CHATSWORTH (*J. H. J.*).—The dimensions of the new conservatory in the pleasure grounds at Kew are the following:—Centre—len th, 212 feet; breadth, 137 feet; height, 60 feet. Orangeries—each, 50 feet in diameter. Wings (not yet built)—length, 112 feet; breadth, 62 feet. Total, when complete, 582 feet long, and covering a superficies of 14 acres. Length of pipes, 3/4 miles. The length of the conservatory at Chatsworth is stated in McIntosh's "Book of the Garden," to be about 282 feet; its breadth, 120 feet; height, about 60 feet.

ROSES IN POTS (*Old Subscriber*).—We cannot give you much encouragement as to growing Roses in a room. They will not do well. You must place them as near the window as practicable, shifting them into larger pots now and using a compost of turfy and rather strong rich loam. At repotting plunge in coal ashes in a sheltered situation, and protect from severe frost by a little dry litter put over them, but removed in mild weather. You may take them into the room in February, and then prune them, cutting the strong shoots to four, and the weaker ones to two eyes. Keep the soil just moist until growth commences, then keep the plants well-watered; sprinkling them morning and evening with tepid water will also be beneficial. After blooming plunge the pots in coal-ashes in an open situation. We shall have an article on the cultivation of Roses in pots shortly, but we think your Roses would be much better planted out. All would do well in the beds, whilst they would afford you but little gratification if grown in pots in a room. *Celine Foster*, *Niphotes*, *S. G. faterie*, and *Comtesse de Barbantanne* would be the better of a wall or a south-west aspect, or at least a warmer situation. The others would form a fine margin to the beds of half standards. The Roses newly planted in the beds should not be pruned until the first week in March.

VINES MILDEWED (*J. N. B.*).—The two Vines that are mildewed had better be coated with a mixture of sulphur and lime in equal parts, brought to the consistency of paint by the addition of soft-soap water, made by dissolving 2 ozs. of soft soap in a quart of water. In order to make this mixture adhere, add to it as much clay as it contains of sulphur. All the Vines should be washed or painted with this composition now, brushing it well into every crevice. The mildew will destroy the Vines unless checked. Should it reappear, dust the parts affected with flowers of sulphur.

LEWISIA BEGGIYA—VARIEGATED IVIES (*A Constant Reader and Publisher*).—All that we know of this plant is that it is a native of North America, and is included in the Natural Order Crassulaceae. It was discovered and named by Pursh, a Prussian botanist, whose "Flora Americae Septentrionalis" was published in 1814. The roots are nutritive, a kind of salep being made from them by the Indians, who collect them in large quantities. We do not know whether our nurserymen have the plant. Our correspondent will be obliged by a list of the best hardy small-leaved variegated Ivies.—*J. H. C.* would be obliged to "J. H." for information as to where the *Lewisia* can be procured and how to grow it.

PERSIAN MELONS (*J. H. Dalton*).—There are many varieties of Persian Melons, and whoever told you otherwise was certainly wrong. McIntosh, in his "Book of the Garden," describes eight varieties of the Persian; we cannot identify a variety of the Melon by its seed; but if you have the *Lepanth*, that is one of the varieties, and excellent.

HISTORY OF GARDENING (*Edington*).—If you send 5s. 6d. in postage stamps you can have Johnson's "History of English Gardening," free by post. It is out of print.

HEATING TWO HOUSES FROM ONE TUBULAR BOILER (*S. S. G.*).—If, in heating two houses the pipes are taken away level from the boiler, you will not be able to sink them in one house, 18 inches, to go under a path-way, if the first level is to be continued afterwards. No pipes should go below the level of the boiler. If a close boiler is low enough to allow the pipes to rise into the lowest house to be heated, you may elevate the pipes as you like in another house. Starting from the same level for both houses will not interfere at all with the good working of the pipes that you raise higher in the second house; but sometimes the flow will be strongest in the house proportionally raised above the boiler. This you can easily regulate by a valve, which will be needed if you wish to have the power of working each house separately.

MEALY BUG ON ORANGE TREES (*H. T.*).—For Orange trees growing in the open air so infested with mealy bug, we would syringe strongly with quassa water, or soft-soap water, say 1 oz. of each to the gallon—if washed with the hand and brushed all the better. In a few days syringe the trees well with clean water at 140°; then have a simple thickish paint formed of melted soft soap and clay, and with a small brush paint the stems and limbs over every little colony, or a single one as it appears, with the point of the brush. This simple paint will imprison the insect and kill them for want of air, and will not hurt the trees, as many other mixtures would be apt to do. We once cleaned a lot of small Apple trees that were eaten up with American blight, by first washing with strong soap water, then painting the trees all over with clay paint, and using this paint to dust up every insect that appeared during the summer. A little soft soap in it prevents its drying too quickly and cracking. Wherever these cracks take place, and there are eggs beneath, the latter will be hatched. Of all paints for insects clay is the cheapest and the best.

EDGING OF HOLLY (*L.*).—An edging, 4 or 5 inches high, of the common Holly, will look very well; the only objection to it will be when leaves are blown into it, as it will be difficult to get them out. We fear, however, unless your climate is mild and moist, you will not succeed by planting cuttings of Holly round the bed in double or triple rows. In most places they require to be protected in winter by hand-lights, the cuttings being inserted thickly in sandy soil in the autumn, when many root the next spring. We think you would succeed much better if you could purchase small plants 3 or 4 inches high.

HEATING WITH HOT WATER (*S. L.*).—We think all the arrangements will do, only as the pipes are sunk under the pathways, we would have four in each place instead of three; and instead of having your central bed sloping like the roof, we would have it of equal height back and front, say from 18 to 24 inches; the plants will then look much better from either pathway. We presume that the side ventilators come down under the ground level, to enter by an opening below the border, and thus the cold air will be brought in contact with the pipes—a very good plan. We hope top air is sufficient. It is all nonsense about the bees influencing the appearance or flavour of different Strawberries planted near each other. They would influence the seeds, but not the pulpy matter usually called the fruit. Messrs. E. G. Hender-on are rich in Cyclamens. It would not suit to print a manual on Cyclamens as you propose.

NEW YORK NURSERYMEN (*A Constant Reader*).—We cannot select from them, but you will find a list in the "Gardeners' Year Book for 1866."

PRICES OF FRUIT (*Mrs. S.*).—Your suggestion cannot be adopted. Dealers will not tell us the prices they pay for wholesale quantities.

GLASS EDGING FOR BOLDERS (*G. T. L.*).—The glass tiles, for this purpose may be had of Messrs. Kilner, glass manufacturers, Thames Street, London.

number each mustered, and I shall speak of pens and not of single cocks. First, Game, the largest entry of all—275 pens. Has not the Game fowl, in spite of cock-fighting being at an end, and not being an over-profitable sort, such a hold upon the English mind that nothing can shake it off? The length of leg in many struck me as being too great. Clearly by the number of entries the Black-breasted and other Reds are still the favourites. Englishmen love "a Red Game cock" as of yore; and yet what a beautiful bird is a Duckwing cock! and what a black prince is the Black Game cock! and how pleasing the symmetry, the chief thing that catches one's eye, in a White one! Next in number to the Game came Cochins—218 pens—yes, not as I expected, Dorkings, but much-abused Cochins; and yet one sees hundreds of Dorkings for one Cochin—so many Cochins, and many so excellent. I greatly admired the first-prize White. Next, not Dorkings but Hamburghs—195 pens, twenty-eight being Blacks. I am sure it is a mistake in the south and west of England people not keeping Hamburghs. Then Dorkings—132 pens. Shakspeare saw your ancestors not far from this place, for I feel proud to be in Shakspeare's county; but he never saw such Dorkings as these, and Justice Shallow's "short-legged hens" were pignies to you, I warrant. I noticed but few Silver-Greys. Bantmas—56 pens, divided, as they always ought to be, into Light and Dark. Spanish—38 pens, and very good. Polish—in all but 35 pens, and yet prizes for six varieties. Twelve prizes to be shared by only thirty-five pens! Why should the Polish go down? In an exhibition no fowls look better; few are so attractive—many crowd around their pens: the Black with white crests nobly contrasting, the Golden handsome, the Silver elegant. Come, brother fanciers, take to Polish. What a good chance of prizes for you! Large breeders, adopt this as an extra variety. Present your wife or daughter with a sitting of eggs next March. Next came Crève Cœur—20 pens, and last of all Malays—13 pens.

I turn now to the pignies. Of Game Bantmas actually 99 pens! Why is this? First, they are very easy to breed, their eggs being almost all fertile; and then they are pretty to look at, and remind Englishmen of Game fowls. Surely the Judges had some difficulty with this class. Throwing aside a few coarse birds, a great number seemed to me "one as good as another." I own I think shows are becoming overburdened with these easy-to-breed miniature Game fowls; and as to profit, with them, of course, there is none. Next—but how far apart!—came the Blacks, which, though true Bantmas in shape and carriage, number only 19 pens; of White there are only 11; of Silver-laced, only 9; of Gold-laced, but 8; and yet, standing for a long time at the end where the Sebrights were shown, I noticed they came in for more admiration than any birds near. It is indeed a pity they are so few. They cost trouble, but what a result if successful! I am thoroughly jealous of the number in which Game Bantmas mustered. Happily the aristocratic Sebrights were far away from them, and I hope did not hear about them, or their feelings would have been hurt. Surely, too, the Blacks are fitted for gentlemen's pets, and White for ladies'. As to spirit, what Game Bantman has more than a Black Bantman cock?

Next, gentle reader, we will go and see the Pigeons. The staircase is steep, so, if a lady, please accept my arm. The Pigeons! Well, here they are along the gallery, in an excellent position to be well seen. There were 331 entered, being a greater number than ever seen before at Bingley Hall. This is well, for people seem too often not to know what charming and ornamental pets Pigeons are. Among the higher-bred Tumblers my preference ran for the Mottled. They also look better in a show than Almonds, not so often standing all of a heap in a corner. The Pouters were better in length than colour; the Carriers good. A special word for the Runts: A pair actually weighed 4 lbs. 15 ozs., others a few ounces less. These large birds deserve to be extensively bred. The Barbs were very excellent. This is also a variety of Pigeon I rejoice to see gaining ground: the Blacks, especially, have so much in them; and oh! those lovely purple and green hues around the neck of the cock. Few Pigeons have higher claims to regard. The white Fantails were better than the coloured, as surely they always are. A coloured Fantail is as painful to my eye as would be a variously-coloured Swan. The Antwerps were too numerous, for what are they but sharp fliers, looking nothing in a pen? Why not more Jacobins? they are worth breeding. The high-bred Balbs were very pretty, but few and not perfect—a foul thigh, a coloured feather on the head, a slobbered cut; but how difficult it is to breed them free from

these blemishes, as I well know! The Dragons were very excellent. I particularly admired Mr. Perivall's Blues. The Turbits were also a good class, and, like the Dragons, drew two "very highly commended" from the Judges. Let me speak a word about the Laced Fantails—very beautiful birds if very clean, though they look like a freak of Nature. There was also a pair of Pribbacks, birds not often seen, and very queer-looking. So much for the Pigeons; would that I could more frequently see such beautiful birds.

I next determined to go for a while to the Dog show, so speedily walked thither. Curzon Hall is a square, with a narrow gallery running all round it. On the ground floor were the larger Dogs, in the gallery the smaller. I began according to number, and passed along noble Bloodhounds, quiet and self-possessed. Why should they be disturbed? They looked perfectly at ease, like true gentlemen, looking at one as if utterly forgetting or despising the crowd, and deeply cogitating some weighty matter, or solving some still problem. On I pass, glancing at shaggy Deerhounds dreaming of their native glens, smooth fawning Greyhounds, strong Foxhounds, then other Hounds. One as I came near happened "to lift up his voice and cry," and what music he made! Then came little Beagles and Pointers of all sizes, lovely to look at—heaten, however, by lovelier Setters; curly-coated Retrievers strong and fierce, as two proved which managed to slip their chains and engage in fierce fight. Then one came upon the "Dogs not used in field sports"—Mutties like Lionesses; Newfoundland; Sheep Dogs with no sheep to watch, and therefore not quite comfortable, "Othello's occupation" being gone. But what now? Oh, those marvellously ugly Bulldozers, but lying so marvellously quiet. "Old King Dick" wrapped in royal slumber, reproving Shakspeare's

"Ureasy lies the head that wears a crown."

Bull Terriers came next, and by no means sleepy, each one apparently regretting that nobody's call came near enough. On to black and tan Terriers, ready to make love to everybody; little Scotch Terriers wriggling their caterpillar-like backs to every one. Pomeranian Pugs, beloved in the last century, figuring in many a picture with their behooped mistresses, and now, it seems, beloved again with crinoline. Dogs and dress equally ugly. I was, however, pleased to notice that some of the seven Pugs exhibited had not had their ears cropped, one of the uncropped taking a second prize, and it was manifest how far less ugly the uncut-ears ones looked. Upon ascending the narrow gallery I observed many visitors leaning and looking over the balustrade down upon the square below, and I followed their example. Truly a beautiful sight lay beneath, for you saw all the different large Dogs at a glance from this altitude. They resembled some marvellously wrought and variously coloured carpet. I felt that I could look upon them for hours. In the gallery were the tiny pets. One Toy Terrier rejoiced in a coat or cloak of green velvet with rich gold fringe or border; and he lay on a cushion made to match his coat, with nothing of his tiny self visible save his sneaky little head. He received no prize, however—perhaps the Judges considered he had gold enough already.

There were in all 781 Dogs exhibited, the larger as a rule very quiet there and there a bad-tempered one, but the small Dogs very noisy, just as with unfeathered bipeds, the little folks making a great fuss and disturbance, while the large people rest quietly on their side and position. Let me not forget to name the inhabitants of the Puppy pen—poor little fellows, so pretty and so bewitched! wondering, perhaps, whether they were always to live in such a busy world. There was a boy, too, combing his pet puppy; and there was a Dog lying one moment motionless, the next he started up and wagged his tail, and gazed forward with bright intelligent eyes; for why?—he recognised his master in the crowd. A horrible thought came into my mind: Suppose all these Dogs went mad, or even all got loose! Then oh! their intolerable barking, it beat its way into one's brain. I could bear it no longer, and I hurried back to Bingley Hall, where, after the yelping and barking, I said to myself, "Welcome, gentle crowing!" I wander lovingly round the Show, I know it is my last visit, admiring again and again some pet pen. How one gets to have one's favourites at a Show, taking one's friends to them, and lavishing our admiration on them. I must say that I could but notice the excellent arrangement of everything. I heard high praise bestowed upon the civility of the attendants. The fowls were beautifully clean; not so, however, some of the Pigeons, with the habit which these birds have of attempting a bath out of their drinking-vessels,

and thereby getting the floor, and, if there is sand or gravel on it, their flight and tail feathers become very dirty. Some of the Pouter I saw in a very filthy state probably owed their condition to these causes. Might I suggest a greater number of water-pots? Of course, these can not be in the Poultry Show, but in other parts. What few there were were watched and watered for the Pouter by the ladies. I was glad to see that the National Poultry Company was making its first known, and that at Birmingham prices. Now that butcher's knout is so dear, poultry ought to pay. Poultry shows are always beneficial, but the one at Birmingham is, I think, especially so. The time of year is somewhat dull; no out-door pleasures save hunting are possible; Christmas's severity has not commenced. Well, the beautiful and extensive Show comes, and affords each year rich and perfectly innocent gratification to thousands. I enjoyed it extremely. It has made a pleasant first impression upon me. Many a time do I, and shall I, close my eyes and imagine myself in Bingley Hall, and live again those happy hours, thinking of my amusements and bewilderment the first day, and my quiet orderly pleasure on the second. I learnt that Bingley Hall was, in old days, a mansion standing in its large high-walled garden. Many a guest did it welcome at Christmas and New Year; but now it welcomes many more. The hosts, so to speak (the Committee), offer a constant source of pleasure, and time does not hang on their guests' hands. All thanks to the Committee. Please everybody they cannot let them be so, and not mind it a bit; but they did thoroughly please. Wm. Rector.

P.S. One little word upon another subject. Last April a great deal of that most precious thing in this world—sympathy, was felt and shown by many of our readers to Mrs. Chitty, widow of one of the writers in this Journal. Her poor husband had died after a few days' illness, leaving his wife and five children penniless. When at Birmingham I was the guest of Mr. Webby, Chitty's master, and although personally an entire stranger, I was received by that gentleman with all an Englishman's kindness and hospitality.

It will be remembered by many that the money collected sufficed to start the widow as a general-shopkeeper in the village in which she lived, and where her husband had been much respected. The last morning of my stay I walked to Solly Oak on purpose to see Mrs. Chitty. It is a village of but yesterday—one of the arms, or rather fingers, of that giant of industry busy Birmingham, which now stretches out many miles into the surrounding country—a village half-grown as yet, with patches of ground marked out for building upon in all directions. Passing houses of more pretension, I at length reached the village street, and soon came to Mrs. Chitty's shop. I had a peep through the window, in which everything was tastefully arranged and beautifully clean. I then sat an hour in the shop, and heard the sad story told, how a life of hard work by day and hard work by night broke down the health of the young and clever workman. It was a shop in which everything looks doubly good from its exceeding cleanliness. I saw and told it to the children, and tried to impress upon the older one their duty to their mother. I heard of much genuine kindness shown to Mrs. Chitty by her poor as well as her richer neighbours, and all seemed satisfactory. Mrs. Chitty expressed much gratitude to all who had helped her, and especially to Mr. Webby, who originated the subscription, and who now aids her by supervision and advice. Apparently she is likely to gain a comfortable livelihood. I make this little statement, for it was a great satisfaction to me to see, as it will be found to hear, that what was kindly done has had so good a result. W. B.

DOTTINGS AT NEWPORT

"Wm. Rector" not being there to see, I may give you a few nights on the Show. First and foremost, I should like to see some things altered at Newport. Lord Tredegar's Show is no longer a poultry affair, but takes its stand as one of the leading bird shows; it therefore ought to move onwards. I think most of my fellow exhibitors would prefer wooden pens to wicker baskets. The latter injure the plumage of the inmates, especially the tails of the cocks. Some, however, of the Newport baskets had no provision made to prevent the neighbouring male birds exchanging civilities with each other. I myself shifted two Polish that were thus engaged. Some of the baskets, moreover, were too small for their inmates. I saw one or two pens that I fancy lost position from the looseness of their baskets, the cock not being able to stand erect without

rubbing his comb against the top. Were this altered, and more light let into the building, it would be a great improvement, and tend greatly to increase the popularity of the Show. I missed well-known names, previous winners there. Could this account for their absence? For in many of the classes the prizes are very liberal. In every other respect the birds were most carefully attended to.

The Game class contained some splendid specimens, the substance and condition of the capons being everything that could be desired. I did not fancy the Dorkings were so good as usual. The capon of Butt Cochins was a most splendid pair—very large good-bred birds, and worth going many miles to see. Miss Milward's were beautiful in colour. The White Cochins were few, but good. Mr. Heath's cup Spanish cock begins to look as if he were going the way of all good Spanish cocks now-a-days; it seems a trouble to him to open his eyes. The extremely warty feet certainly disfigure them. The comb of this bird does not please me. I cannot agree with your reporter as to the Bantams. There have been much better competitions at Lord Tredegar's Show in previous years. This year I only saw two respectable pens. As the falling-off of entries in this class, now becoming so popular, to be attributed to increased entry payment without any increase of prize money?

Hamburghs mustered strongly, and there were very good specimens of all the older varieties. I did not like to see the prize card of another show struck off pens of birds that were here only highly commended. I thought it bad taste. It was done after the awards. The Gold and Silver Polands were few in number but good in quality. The Silver-laced cup Bantams were little pictures. The same may be said of Mr. Zurbast's Sultans—quite one of the gems of the Show—faultless in condition, &c. La Fleche may have good qualities, but certainly not beauty. Does any person doubt me? If he cannot see a living specimen, let him notice the drawing of Birmingham prize birds, in the *Illustrated London News*, and judge for himself. (N.B., if of nervous temperament the experiment had better be avoided.) A pen of blue Crève Coues were unnoticed. These birds were slate-coloured, like the Andalusians in face and colour; but the hens had top knots, the cocks, I think, being defective. A Crève Coue cock in the Single Cock class was exactly opposite a bad Silver Poland with developed comb, and they looked first cousins. Again I did to myself, "Dearest Poland!" Several of the Black Hamburghs had the white of the earlobe extending over the face, and again I said to myself, "Dred from Minoras!" Turkeys, Geese, and Aylesbury Ducks were very good.—Y. B. A. Z.

RAILWAY CHARGES.

The thanks of every exhibitor are due to "Y. B. A. Z." and "J. K." for so ably using their pens in the matter of "railway charges," as most must have suffered from nearly every previous exhibition mentioned. At many shows this year where I have been a successful exhibitor, it has been, as "J. K." says, "rather galling to find the prize-money, and even more, swallowed up in railway carriage," and to many this must prove a drawback. There can be no doubt that railways benefit by poultry shows, as not only do they carry the poultry, but, in many cases, the owners also. I myself have travelled hundreds of miles to a show, seldom alone, and find ladies prefer first-class and express trains; and, of course, this is the case with many others. I have in some instances received back the return railway carriage on application, but what is wanted is a general rule that no back-carriage shall be charged on poultry, or at any rate that the charges should be modified. I am glad to see "Y. B. A. Z." "hopes shortly to propose a remedy," and I trust it will be taken up, and tend to remove this grievance, so important to all. For, for one, shall certainly next year curtail my entries at shows on those lines where back-carriage is doubtful, and, on the other hand, send as many as possible on those lines consenting to return the birds un-sold free. I also fully agree with "Y. B. A. Z.'s" remarks on the delay in sending exhibition labels.—E. P. L.

MIDDLETON ORNITHOLOGICAL ASSOCIATION.—The first Exhibition of this Association is to be held at Middleton, near Manchester, on the 9th and 10th of February. There are fifteen classes for Canaries, twelve for British and foreign birds, and twelve for Pigeons, in most of which two prizes are offered. The entries will close on Monday, the 5th of February.

WHITEHAVEN POULTRY AND PIGEON SHOW.

THE success of the Whitehaven Poultry Show, held last week, was so great as to take the Committee by surprise, as between seven and eight hundred entries were received, and the amount of empty pens was unusually small. Gratifying as this must have been to the Committee, the accommodation of so large a collection of poultry presented no small amount of difficulty; but, by the kind permission of Lord Lansdale, the Riding School was placed at their disposal, and, consequently, accommodation for all was at length provided. We certainly ourselves could have wished for pens of somewhat larger size for Spanish, Dorking, Game, Cochins, and Brahma fowls, as the birds would have been seen to far greater advantage; but this difficulty admitted of but little compromise, as some of the Brahmas were hoisted fully 6 feet from the ground. If the numbers should progress with equal rapidity on future occasions, it would be advisable to erect an additional tent in the enclosed yard surrounding the Riding School, for the accommodation of some of the most hardy breeds. The extraordinary increase of entries this year attests, however, that the public confidence in the Whitehaven Committee is strong, and certainly no body of gentlemen could be more persevering in their efforts to do everything possible for the benefit of the poultry whilst under their care.

The competition in *Game fowls* was unusually severe, as may be easily gleaned from the fact that in the classes devoted exclusively to single Game cocks there were no less than seventy-three entries. The other classes of Game fowls were also well filled. It was a matter of regret to find the most unbusinesslike "trimming" of the hackles of some of the Game cocks, which led to their discomfiture; but such practices, when discovered, must be suppressed, in common justice to those exhibitors who feel a proper disinclination to adopt such measures to secure prizes. The total abstraction of the feathers over the eye in some of the *Spanish* fowls is equally deserving of censure. The *Dorking* classes were unexceptionably good—a proof, if any were wanting, that this excellent variety of fowls can bear with impunity the severity of a northern climate if the sulcol is dry. The winners of the Dorking prizes may, therefore, well be proud of their success. The *Cochins* were perhaps a good, or even better than are usually to be met with at this time of the year, most of them being shown in perfection of feather and condition, though a few of the earlier-hatched pullets of last year were beginning to show symptoms of broodiness. In *Buffs*, which were the best classes in the Cochins, Mr. Charles Jenkinson, of the Belle Vue Gardens, Manchester, had a singular amount of success; his extraordinarily good pen of adults having awarded them the following prizes at this Show for their lucky owner—viz., first in their own class of old Cochins; then the Three-Guinea Silver Cup for the best pen of Cochins or Brahmas shown; and again the Five-Guinea Silver Cup for the best pen of poultry of any kind in the exhibition. The principal prize for Buff chickens was also secured by the same breeder. It would be a very difficult task to bring together a better show of *Hamburghs*; though undoubtedly the Spangled ones were the most praiseworthy, all the varieties were shown in excellent feather. It must be borne in mind, however, that with a perfection in all other characteristics is quite incompatible with some, as if coupled with willow-coloured legs in any of the Hamburgh family. *Puffs* were truly excellent, whether Black with White crest, silver-spangled, or Golden-spangled; these varieties all competing together, and proving one of the gems of the Whitehaven Show. The *Game Bantams* were first-rate; but the *Sabots*, although from long-crested breeders, fell far short of those shown by the same exhibitors only a few years ago. It is apparently a fact that this expensively beautiful fancied is fast fading away. A class for the exhibition of a "Dozen Hens' Eggs," with the offer of a piece of plate for a first, and two other prizes, brought twenty-six competitors, all good without a single exception.

In *Pheasants* the show was good, and most of the classes were well filled. The *Powers* were remarkably good, the cock in the first-prize pen measuring 19 inches. Some very good *Dun Carriers* were generally admired. The *Fantails* and *Turkots* were also very good; *Trumpeters*, *Hunts*, and the *Siberian Ice Pigeons* all adding to the general attraction.

The Committee enjoyed the most favourable weather on the day of opening, so much so, that amid the brightest sunshine everything around remained visitor, in spite of the serenity of a May-day than being one at the very commencement of the year. The success of the Show was therefore secured.

SINGLE COCKS.

COCHIN.—First and Third, Sir St. G. Gore, Bart., Hopton Hall, Derbyshire. Second, J. H. Wilson, St. Peter. Fourth, C. W. Brierley, Middleton, Manchester. Fifth, T. Whitaker, Melton Mowbray. Commended, T. Stutter, Hull; C. W. Brierley; A. B. Dyas, Madeley, Salop. *Cockrel*.—First, J. Fletcher, Stonehouse, near Manchester. Second, R. Pickering, Carlisle. Third, Sir St. G. Gore, Bart. Highly Commended, A. Fenton, Rochdale; H. Thompson, Maryport. Commended, J. Fletcher; M. W. St. Bart, Darlington; J. Brough, Carlisle.

GAME.—First and Second, W. Jones, Wigton. Third, J. H. Wilson. *Cockrel*.—First, J. H. Wilson. Second, Messrs. Gunson & Jefferson, Whitehaven. Third, T. Smith, jun., Harrington, Cumberland. *DORKING*. (Any colour).—First and Second, Messrs. Gunson & Jefferson. Third, T. Dixon, Whitehaven. Highly Commended, Mrs. A. Park, Whitehaven.

SPANISH.—First, J. Bowman, Workington. Second, W. Hale, St. Bees. Third, J. H. Wilson.

COCHIN-CHINA (Any colour).—First, Messrs. Gunson & Jefferson (Buff). Second, J. Bowman (Buff). Third, J. H. Wilson.

HAMBURGH.—First, W. G. K. Jones, Parton, Whitehaven (Golden-spangled). Second and Third, Mrs. A. Parke (Silver-spangled and Golden-spangled). Highly Commended, J. Bowman (Golden-spangled). Commended, H. J. Nicholson, Fringinton, Whitehaven (Golden-spangled); W. Robinson.

BANTAM (Game).—First and Third, Mrs. A. Parke. Second, E. Fearon, Whitehaven.

GAME (Black-breasted and other Reds).—First, J. Geldred, Collin Croft, Kendal. Second, Sir St. G. Gore, Bart. Third, J. H. Wilson. Highly Commended, A. B. Dyas. Commended, J. Fletcher.

GAME (Duckwing and other Greys and Blues).—First, Sir St. G. Gore, Bart. Second, J. Fletcher. Third, E. Aykroyd, Bradford, Yorkshire. Commended, W. J. Cope, Barnsley.

GAME (Any other variety).—First and Cup, J. Fletcher (Piles). Second, Sir St. G. Gore, Bart. (Piles). Third, T. Whittaker (Piles). Commended, J. Brough. *Pullets*.—First, J. Robinson, Sunderland. Second, J. H. Wilson. Third, J. Harris, Wigton. Highly Commended, E. Wilson, St. Bees; J. Gaddes, Carlisle.

DORKINGS (Silver-Grey).—First, J. Rowlandson, Hawk-head, Copiston. Second, R. D. Holt, Orresthead, Windermere. Third, J. Hardie, Saddle Lows, near Langholme. Commended, R. D. Holt. *Chickens*.—First, J. D. Steele, Windermere. Second, J. Rowlandson. Third, W. H. Walker, Shenfield, Brentwood, Essex. Highly Commended, R. D. Holt; J. Hardie. Commended, T. Atkinson, Coniston Lake.

DORKINGS (Any other variety).—First and Cup, W. Cottle, Eccleston, Prescot. Second, R. D. Holt (Dark Grey). Third, A. Fenton (Coloured). Commended, A. Woods, Sefton, near Liverpool (Coloured); J. Robinson; Sir St. G. Gore, Bart. (Coloured). *Chickens*.—First, Sir St. G. Gore, Bart. Second, W. H. Walker (Coloured). Third, C. Jenkinson (Coloured). Highly Commended, W. Cottle. Commended, T. Rogers, St. Helen's, Lancashire; J. Fox, St. Bees.

DORKINGS (Any colour).—*Pullets*.—First, R. D. Holt (Dark Grey). Second, W. Cottle. Third, Messrs. Gunson & Jefferson. Highly Commended, Messrs. Gunson & Jefferson. Commended, J. H. Wilson.

SPANISH.—First, H. Beldon, Bingley, Yorkshire. Second, E. Brown, Sheffield. Third, J. H. Wilson. *Chickens*.—Silver Cup, R. E. Postans, Brentwood. Second, H. Beldon. Third, E. Brown. Highly Commended, J. Hardie. Commended, R. Pickering; J. Marchant, Halifax.

SPANISH.—*Pullets*.—First, J. H. Wilson. Second, J. Marchant. Third, J. Bowman.

COCHIN-CHINA (Cinnamon and Buff).—Cup, C. Jenkinson. Second, Miss F. A. Aglionby, Grassmere, Westmorland. Third, J. Poole, Everton, Highly Commended, W. Dawson, Houghton Bierfield, Yorkshire. Commended, H. Beldon; C. T. Bishop, Birmingham. *Chickens*.—First, C. Jenkinson. Second, J. Poole. Third, Miss E. A. Aglionby. Commended, W. H. Walker; W. Wood, Walkley, Sheffield.

COCHIN-CHINA (Any other variety).—First, W. A. G. Jones, Kirby Lonsdale (Partridge). Second, R. J. Wood, Chorley, Lancashire (Partridge). Third, E. Smith, Middleton, Manchester (White). Highly Commended, R. J. Wood (Partridge); W. Cottle (White). *Chickens*.—First, J. Wood, Chorley, Lancashire (Partridge). Second, J. Poole (Grouse or Partridge). Third, J. Bowman (Partridge).

COCHIN-CHINA (Any colour).—*Pullets*.—First and Second, C. Jenkinson. Third, J. Wood. Commended, J. Poole; Miss E. A. Aglionby.

FRANCA POUTRA (Any variety).—First, Rev. W. H. Fell, Statton, Ponton-le-Fylde (Dark). Second and Third, withheld. *Chickens*.—First, E. Sherman, Cheston (Dark). Second, J. Bowman. Third, J. Poole (Dark). Highly Commended, G. H. Roberts, Fenwortham, near Preston. Commended, Rev. W. H. Fell (Dark).

HAMBURGH (Golden-spangled).—First, Sir St. G. Gore, Bart. Second, A. K. Wood, Barnside, Kendal. Third, R. Tate, Green Road, Leeds. Highly Commended, H. Beldon; W. F. Dixon, Horestay, Whitehaven. *Chickens*.—First, H. Beldon. Second, J. Koe, Radcliffe, Manchester. Third, Sir St. G. Gore, Bart. Highly Commended, R. Tate; J. H. Wilson.

HAMBURGH (Silver-spangled).—First, A. K. Wood. Second, J. Robinson. Third, Sir St. G. Gore, Bart. Highly Commended, H. Beldon; J. Bowman. *Chickens*.—First and Cup, J. Robinson. Second, Sir St. G. Gore, Bart. Third, H. Beldon. Highly Commended, J. Smalley, Blackburn. Commended, J. Hargraves, Carlisle.

HAMBURGH (Golden-pencilled).—First, R. Burrow, Longtown, Sunderland. Second, Sir St. G. Gore, Bart. Third, A. K. Wood. Highly Commended, H. Beldon. *Chickens*.—First, A. K. Wood. Second, W. Dowe, Carlisle. Third, H. Beldon. Highly Commended, J. Robinson.

HAMBURGH (Silver-pencilled).—First, Sir St. G. Gore, Bart. Second, A. K. Wood. Third, H. Beldon. *Chickens*.—First, Sir St. G. Gore, Bart. Second, A. K. Wood. Third, C. Moore, Poulton-le-Fylde. Highly Commended, J. Preston, Alorton, Bradford.

HAMBURGH (Any other variety).—First, E. Smith (Black). Second, Sir St. G. Gore, Bart. (Black). Third, G. Lingard, jun. (Black). Commended, H. Beldon (Black). *Pullets*.—First, R. Burrow, Cumberland. Second, J. Robinson. Third, H. Beldon (Black). Commended, A. Woods; A. K. Wood.

POLAKES (Any variety).—First, J. Smith, Keighley, Yorkshire (White-crested Black). Second, H. Beldon. Third, Mrs. Procter, Hull (Silver). Highly Commended, H. Beldon; E. Smith (Silver). *Chickens*.—First, H. Beldon. Second, Mrs. Procter (Black). Third, J. Smith (White-crested Black).

GAME BANTAMS.—Cup, First, and Third, R. B. Postans. Second, C. W. Eriehy, Highly Commended, A. Fenton; Sir St. G. Gore, Bart. Commended, J. W. Morris, Rochdale; W. H. Walker; R. Tate.

BANTAMS (Gold or Silver-legged).—First and Second, M. Leno, Markgate Street, near Dunstable, Bedfordshire (Gold-legged and Silver-legged). Highly Commended, J. W. Morris (Silver-legged); G. Manning.

BANTAMS (Any other variety).—First, W. J. Cope (Eckings). Second, H. Beldon. Highly Commended, Sir St. G. Gore, Bart.

ANY NEW OR DISTINCT VARIETY NOT PREVIOUSLY MENTIONED.—First, W. Wood (White Malays). Second, E. Smith (Sultans). Third, Messrs. Gunson & Jefferson (Grey Malays).

SELLING CLASS.—First and Second, H. Beldon (Golden-spangled *Hamburghs* and Silver-spangled *Polands*). Third, T. C. Harrison, Hull (Drum)

This pen obtained the first prize in its own class, the three-guinea Silver Cup for the best pen of Cochins, and the five-guinea Cup for the best pen of poultry in the Exhibition.

sideration, awarded to Mr. Boyle. Pencilled *Hunts* were watched. Spangles were good and admirably judged, as also were *Polands*.

Ducks were a very large and fine show; *Geese* and *Turkeys* of most marvellous size, the Hon. Mrs. Arbuthnot's first-prize pen of Turkeys weighing 63 lbs., cock and one hen.

Bantams were a beautiful show. We need only mention the names of Messrs. Leno, Raynor, Crossland, Hodgson, Anderson, and Manning. *Single* birds were a poor show, except *Cochins*. The local birds were first-rate.

Mr. Dixon awarded the prizes, of which a list appeared in our last Number.

THE POULTRY BOOK.

By W. B. TEGETMEIER. London: G. Routledge & Sons.

We have received the commencement of this work, which is proposed to be completed in fifteen monthly shilling parts. It is "The Poultry Book" published some years since, edited by Mr. Wingfield and Mr. Johnson, re-arranged with additions. We think it right to apprise our readers of this, as Mr. Tegetmeier's name only appears on the cover and in the advertisement, from which they might be led to believe that it is the production of that gentleman.

A SHOCK TO THE NERVOUS SYSTEM.

In your report of the Aberdeen Poultry Show you give the name of Mr. H. Ashton, of Manchester, as the winner, with a pen of Nankin Bantams, of the third prize in the Selling Class. If you will refer to the printed prize-list of the Show you will find a pen of Black Red Game Bantams of mine marked also as third prize. When my basket of birds was returned to me it contained the printed card marked "Third prize." As there were fourteen entries in this class, and the names of the two third-prize men occur at each end of the list, it is clear that the mistake in the catalogue is not the fault of the printer, and that the "third-prize" card could not have been slipped into my basket by mistake.

At the last Farnworth (Chapelry) Poultry Show, for which, by the way, my direction labels did not arrive until after I had sent the birds with labels of my own, a very fine pen of my Game Bantams returned with the first-prize card in the basket. Then came a letter from the Secretary, with an apology that he could not send me a prize-list, which I had written beforehand to secure, as they were all sold on the day; and a polite intimation that I was "fairly beaten" by three exhibitors, whose names were given, but of whom I had never heard before, although I read the prize lists of all the shows attentively in those classes, which are my fancy. As no report of this Show appeared either in your paper or your sporting contemporary, whatever honour I may have won or lost remains in obscurity. I do not complain that I was "fairly beaten" at Farnworth, although I do not like the phrase; but I do complain that I had a first-prize card without the prize, that I had not a prize list, and that the Show was not reported in the poultry journals.

I shall be much obliged if you will insert this, as I am one of those people whose lives, according to the "WILTSHIRE RECTOR," ought not to be accepted by insurance offices, "because exhibiting must be so wearing to the nervous system."—GEORGE MANNING, *Springfield, Essex.*

You say, "Selling Class (Any variety). Third, H. Ashton, Nankin Bantam." My birds at the time of the Aberdeen Show were in my poultry-yard, many miles from Aberdeen. I sent nothing at all.—HOWARTH ASHTON.

VULTURE-HOCKED COCHIN-CHINAS.

I AM very glad that our Editors have expressed an opinion so decidedly upon the subject of vulture hocks. There can be no doubt that the subject has been allowed to remain unnoticed too long, and that the time has now arrived for it to be brought boldly forward, and fully and freely discussed. By having neglected to do this, an opinion has been growing and spreading, that any approach to the vulture hock is exceedingly objectionable, and I am sorry to find that some of our judges have evinced their agreement with this opinion by withholding prizes from such birds as have had this particular mark. It is certainly very mortifying to an exhibitor whose pen is unquestionably the best in the class, barring this supposed defect, to

see it passed coldly by, while others which are far below the mark come off with flying colours.

It is sheer nonsense to affirm that the vulture hock, although objectionable, is not a disqualification. The fact speaks for itself. It has disqualified and put to the right-about many a pen which has been ten times more deserving of honour than those upon which it has been bestowed. That such a judgment is somewhat arbitrary must be readily granted by any one who looks fairly at the matter. Why, it is but a very short time ago, that the vulture-hocked Brahmas (I refer more especially to the Brahmas) were the most admired and the most successful competitors of this class at our annual shows. We never heard till lately of this profuseness of feathering at the hock being a defect. It was, I believe, rather considered an ornament. Certain I am that it pertains to those birds which carry the heaviest fluff, have the shortest, best-feathered legs, present the finest figure, and attain the largest size. Why should it be pronounced a drawback? It was not thought so three or four years ago. Their parents came off triumphantly from many a hard contest, and why should not the same laurels be awarded to their offspring? Why should they be doomed to ignominy and defeat while less deserving competitors are crowned and applauded? Poor, innocent creatures, what have they done? Why must they be pecked, and cuffed, and virtually set down among the mean and disqualified? What shadow of a reason can be assigned for all this? Has any new discovery been made to sanction and justify this sweeping condemnation? Has their blood become tainted? Have they degenerated in colour, in calibre, in form, in spirit, in carriage, or anything else, so as to forfeit the rank and prestige which belonged to them in former years? If so, let it be clearly proved, and I will spread my agis over them no longer; but if the prejudice against these matchless birds be nothing more than a mere fancy, a mere matter of taste, and which has been allowed so to bias and warp the judgment of our Judges as to consign them to the dust of inevitable defeat, I beg permission, through the columns of this admirable Journal, to enter my respectful but earnest protest against this prodigious wrong.

Are gentlemen who have been at considerable expense and trouble in purchasing or rearing these fine specimens to sit down quietly and see them coolly put aside, or rather unscrupulously immolated upon the altar of caprice? If what is sanctioned one year may be reprobated the next, what ground of security have we to stand upon? The shape of a coat or a hat may be altered from time to time as the winds of fashion may happen to blow, but to allow our feathered friends to be subjected to such perpetual shiftings, would be expensive, whimsical, and absurd. Do this, and we at once expose ourselves to the merited charge of running poultry-mad.—JESSEIA.

THE DISEASES OF BEES.

(Continued from page 535.)

FOUL BROOD.—Any description of the diseases of bees must necessarily be incomplete without some notice of what Dzierzon most correctly states to be "incontestably and beyond comparison the greatest misfortune that can befall the bee-keeper;" but as the long discussion on this subject, which commenced in the autumn of 1863, must be fresh in the recollection of many of my readers, I will refer to it as briefly as possible.

This disease, which, as its name implies, affects not the adult bees but only the brood, appears so far to have baffled all attempts at discovering its origin. It attacks the young larvae in their various stages of development. At first only a few die; but these are not removed by the bees as is the case with chilled brood, and, as they putrefy in their cells, the infection spreads until but very few bees arrive at maturity, the brood combs become masses of corrupt and most offensive matter, and the stock dwindles and ultimately perishes. It is a singular fact that the diseased brood is, at any rate sometimes, inverted in the cells*, so that even if it arrived at maturity the young bees would be unable to liberate themselves, and this has given rise to the absurd idea, promulgated by some old writers, that all the mischief arises from the queen depositing her eggs with the wrong end upwards! I need hardly say that this ridiculous notion is incorrect, nor do the unfortunate larvae ever arrive at the stage at which they would perish simply from being unable to liberate themselves from their confinement. They seem to die soon after they have

* I am uncertain as to whether this is invariably the case.

from scale-brood, and it would appear that a peculiar form of degeneration set in which changes them into a brown viscous pulp, which the bees make no attempt to remove from the cells.

It may be stated that there are two forms or phases of this disease, one mild and curable, the other violent and nearly incurable, and that the former is liable to degenerate into the latter. When this takes place the make assumes a most infectious character, the bees, combs, honey, propolis, nay, even the very hive itself, become as it were saturated with the unhealthy virus, and each and all are capable of inoculating healthy stocks. For this reason one diseased colony may infect a whole apiary, and one such hive in which the bees have died may become the centre of contagion to an entire neighbourhood, if suffered to remain exposed until plundered of its contents. As the violent type of this disease was unfortunately the one with which I made acquaintance in 1863, I can fully endorse the conclusion arrived at by Dzierzon—viz., that looking at the probability of failure, and the risk of spreading the infection, it is unadvisable, except under very peculiar circumstances, to attempt the cure of a foul-breeding stock; better, far better, to consign the bees to the bin-stomper, drain the honey (which may be used for any purpose except feeding bees), melt the combs, and let the proceeds go towards the purchase of a new stock; whilst the hive itself should either be burnt or carefully purified in the manner hereinafter to be described.

As in my own case peculiar circumstances did exist, and I could neither think of exterminating my Ligurians, nor of consigning my entire stock of valuable hives to the flames, I will briefly describe the process by which, after many vain attempts resulting only in a series of vexations and almost heart-breaking disappointments, I at length succeeded in restoring my apiary to its former state of perfect health, and from which no relapse whatever has since taken place.

The bees and queen of an infected hive having been driven from their own domicile should be placed in an intermediate hive for four days, during the whole of which period the queen must be imprisoned in a queen-cage. At the end of this term my combs made in this hive should be destroyed, and the bees again transferred to a new domicile in which they are permanently to remain, and which is all the better if furnished with a few pure worker combs. It is well even then to keep the queen confined a day or two longer until comb-building has commenced, when, upon her release, she will proceed to lay eggs, which, if the matter has been properly managed, will probably hatch into healthy brood. Infected hives, if straw, should be burnt; if wood, should be carefully scraped over, the refuse scraped off being scrupulously burnt, and they should be thoroughly washed with a saturated solution of chloride of lime, which, in its turn, may in a day or two be washed off with clean water. If the hive can be spared it will be the safest plan to put it by unused for a couple of seasons.

Such, then, is the description and treatment of foul brood, which, at the risk of repetition, I have ventured on transcribing, but which may also be found more fully detailed in my communications to "our Journal" during the autumn of 1863. In concluding my notice of the Diseases of Bees, I may be excused for giving expression to the hope that none of my readers may at any time realise the woful experience of foul brood, which at that time befel—A DRYOSHINA BEE-KEEPER.

WINTER VENTILATION.

I have, with delight, in common, I feel certain, with every reader of the apianian corner of "Our Journal," the first contribution of our talented transatlantic brother, the Rev. L. L. Langstroth, the pioneer, it is to be hoped, of many more, alike excellent, opportune, and useful.

From having been bee-keeping, I may say, by observing and operating on stray colonies long established in our roof, I can fully bear out what our correspondent says with reference to the intolerance of bees to cold, always providing their domicile be kept dry and sweet. I would even say they prefer a rather cool position, from having remarked that such vagabond swarms usually select those portions of roofs having a northern aspect, possibly from the greater coolness there enjoyed during the extreme heat of summer, coupled with the additional advantage of thorough dormancy during the winter months, and a consequent saving of store.

That bees may be wintered almost equally well in wooden

hives with those of straw by the mode recommended by your contributor, I have not a doubt; nay more, I have proved that even in those of glass our little favourites may bear an amount of cold almost incredible, and come through as dry and healthfully as in a straw hive by a mode that similarly is untriviale. The case alluded to and chronicled in the time in these pages was that of a large square observatory hive of glass, whose stance was a stained-glass window. The thermometer on the memorable morning of the 24th of December, 1863, indicated 25° of frost within the hive, while in the comparatively shelter outside the windows it fell to 1° below zero, and, nevertheless, the inmates came out of this trial in beautiful order. This welcome, though unexpected result, I chiefly ascribed to the thorough ventilation and consequent dryness afforded by my having employed strips of India matting as a substitute for the usual wooden slide. Let me on this point, when constructing the hive, I must, however, state that I would give a decided preference to matting covered with woollen for ventilating purposes, from the greater facility with which the surplus moisture is allowed to escape through the former, and its not being so readily absorbed and retained as in the latter, avoiding the risk of the woollens becoming damp and dirty, besides the greater chance of their affording shelter to mites and vermin.

What a contrast the extreme mildness of the past December presented to the severity of that of 1860. In sheltered nooks along the bank of the Clyde a crop of strawberries and even pears has been gathered, while spots of laburnum blossom are by no means uncommon. Is it to be wondered, then, that in our Leith, Wicker, and more inland localities the fairs should be bursting into a glow, while little clouds of youthful yellow-jackets gambol in the stray beams of sunshine, while older stagers lie off to nibble the bursting blossoms? An Ayrshire correspondent informs me that fairs in blossom and bees gathering pollen in December, are events unprecedented in the memory of their oldest apianians.—A RANUNCULUS BEE-KEEPER.

OUR LETTER BOX.

PREVENTING SOFT BEES.—(C.) There is a deal to be done in this measure. It is always considered that the honey has the grain in itself, but the shell is composed of wax, and is not so hard. The substance must be supplied by paying some attention to the quality of the bees' gums. Taking this, all the dirt is got out of the back of the whole comb given to them. That is not soft, but, notwithstanding, as a check to it of brickdust or similar. This will have a check for the mortar between the bricks of the honeycomb, and the honey will be hard.

BONNIES' COMBS.—(B.) The change from a higher to a lower temperature will often cause the change in the colour of the tips of the combs of certain kinds, the same morning will do it. If they are in health, the bees will soon recover their real colour, save in very hard weather, when the tips may turn white, and ultimately fall off. A little stimulant, some bread soda, if in good case, will often rid the bees of the blackness.

SIX-SIXTY FOWLS IN 1855.—(B.) We know of no point in Spanish in which there has been an improvement during the past year. We have seen no birds equal to those shown by Mr. Ryley and Mr. Davy's pairs, 225. The cocks had stature and style. The same birds had large, yellow, pendant faces, and combs as stiff as if they were part of metal, and of large size, and fullness of structure. The hens were very good, and soft looking combs, and perfect feet. These points were all shown in faultless perfection, but they were none of the characteristics of a pen. They are met with in single birds, but we do not see faultless pairs of these birds as we did formerly. Inquiries about them was very difficult, but many of those now shown are copies of it.

BOOKS, &c.—It is a work of little value, and will never be reprinted probably. You will find all you need in "The Poultry-keeper," No. 147, just published at our office.

THE CRAYON, &c.—We believe that of Messrs. Crook's and "Inventor." For seven postage stamps you can have "The Poultry-keeper" and "The Many," free by post from our office. It contains a plan of a house and separate yard.

DR. DYER'S FERRIC.—Mr. O. Dyar, Post, Navy Arms, High Street, 671 Brompton, Kent, would be obliged by any bee-keeper whose bees are suffering from dysentery allowing him to make trial of a new remedy. The last winter were heaved to be cured by it, but Mr. Dyar's remedy is not so good if further before making it public.

MAKING POTATO SUGAR.—(J. H. W. C. 1055.)—Grind the Potatoes in a mill; mix this thoroughly with water, and stir thoroughly. After standing six hours pour off the clear water—the sediment is Potatoes-juice, though not quite pure. One part of this Potatoes-juice is to be boiled with four parts of water, one-fifth of oil of Vitrol, during thirty-six or forty hours; the water which evaporates being added. The jelly does not assume any consistency; the liquor remains clear, and the material used is found completely converted into sugar. By means of chalk the acid is removed, and the solution being evaporated, the clear crystallises.

POULTRY MARKET.—JANUARY 15.

The supply of poultry remains good, with an average demand. When the game season is over we may look for a slight advance of price, which will, in all probability, be progressive. Turkeys of good quality are valued just in proportion as they are heavy.

WEEKLY CALENDAR.

Day of Month	Day of Week.	JANUARY 23—29, 1866.	Average Temperature near London.			Rain in last 39 years.	Sun Rises.		Sun Sets.		Moon Rises.		Moon Sets.		Moon's Age.	Clock before Sun.	Day of Year.

29	M	Jasminum nudiflorum.	45.6	31.6	38.6	17	46	7	41	4	45	3	16	6	13	15	29

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 45.0°; and its night temperature 32.0°. The greatest heat was 57°, on the 29th, 1863; and the lowest cold 15°, on the 25th, 1827; and 27th, 1855. The greatest fall of rain was 0.90 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

ROSES ON THEIR OWN ROOTS.

LAD am I that the subject of growing Roses on their own roots has attracted the notice of some of your correspondents, and I flatter myself that further experience will

bring more converts to the ranks of those who dislike the trouble of working Roses, and, what is more, the inconvenience attending them afterwards. I must, however, in the first place state that my experience of worked Roses on the Manetti stock has not been very extensive; but I have had several hundreds on the briar, and a tolerably good number on the Manetti also, the latter being mostly dwarfs or half-standards.

I have read with much interest the many articles which your worthy correspondent Mr. Radclyffe has written on the queen of flowers: but, having grown many Hybrid Perpetuals on their own roots for some years with success, I am rather disposed to differ from him when he says that they require great care the first year, as my opinion would be that the worked ones require the care to prevent the suckers usurping to themselves the whole energies of the plant, and that those on their own roots merely need to be let alone. In the spring of 1857 I planted out about two hundred Hybrid Perpetual Roses on their own roots; they were not by any means over-well rooted, and had been lying about some time before planting, which was late in the season. I had occasionally planted some before that time, but less extensively; they succeeded so well, however, that in the following year I planted more, and nothing could possibly have thriven better than they have done, they being rarely affected with aphides, and never to the same extent as those worked on the briar or Manetti. One or two of the beds that were first planted are still doing well, but some alterations involved the removal of the bulk of them a year or two after they were planted; they were replanted, and have succeeded so well that, more Rose-beds being wanted, we planted last year about five hundred more of the same kinds on their own roots.

So much for this side of the question, let us take a view at the other, and this is not without its defects, but I would rather they were narrated by some one who has experienced more reverses than I have: for, with the exception of some kinds not doing well, I cannot find a single fault, as they are as strong and vigorous as could be desired, and the flowers individually are much finer and larger than those of the same varieties on stocks. Some blooms of General Jacquemot, which were produced last year, were the largest I ever saw. Such old kinds as Jules Margottin, Alexandrine Bachmetell, William Griffiths,

William Jessie, Souvenir de la Reine d'Angleterre, Auguste Mié, Baronne Provost, Duchess of Sutherland, Pius IX., Caroline de Sansal, La Reine, Mrs. Rivers, Mrs. Elliot, and several others are as vigorous as any one could wish. Whether the non-success of a few arose from the varieties not being adapted for the purpose, or whether they dwindled and did not grow well in consequence of the unfavourable season that followed their planting (for that was done in the cold spring of 1860), or from some other cause, I cannot affirm, but several kinds which I had from an eminent nurseryman died in the following winter, or rather they dwindled away during the cold summer preceding the memorable frost at the end of that year. I am, however, far from certain that these might not have succeeded well if planted in any other season; but as the beds of which they formed a part required to be kept somewhat uniform, I preferred planting the second time with kinds that had been found to answer. I may add that the soil is dry, but not so much so as to starve them, but a good useful garden soil of fair depth, and that the situation is sunny.

I have urged all who want plenty of good Rose blooms for cutting for bouquets, or even for the appearance of the plants in a growing state, to have these on their own roots, as, with the exception of perhaps cutting out one or two coarse shoots from a bed (not from every plant), during the summer, keeping the weeds down, slightly digging the ground in autumn, and pruning them in winter, such Roses receive no other attention. There is no fear of mistaking the stock for the worked part of the plant as in the case of Roses grown on the Manetti; and I confess having more than once made such a mistake myself in a solitary plant, and mistakes of this kind are by no means uncommon. A year or two ago, in walking round a garden with a gentleman fond of floriculture, he pointed out, with some exultation, the vigorous condition of his Roses, and called my attention to them. A short glance revealed the fact that, with the exception of one or two of the weakest of them, the rest were a mass of Manetti; and as he had in the previous year determined to increase his stock of plants growing on their own roots, cuttings had been taken in abundance, and they struck beautifully, and other beds of bristly Manetti exhibited themselves in another place. Now this is not a solitary case. Much of the work of the most eminent gardeners in the country must be left to labouring men, and they can hardly be expected in all cases to distinguish between Manetti and other kinds of Roses resembling that stock, or, perhaps, many may not know that such plants really are on stocks. Now, there is none of this trouble when Roses are on their own roots. Briars are worse for suckers than the Manetti, only they are never mistaken, but as they spread further they are often in the way of other cropping. All this, however, is so well known to the practical Rose-grower that more on this head need not be said here.

I may observe, and I do so in some degree with regret, that the Hybrid Perpetuals of such kinds as those mentioned above do not furnish any suckers, so that recourse to cuttings must be had for fresh plantations; and the process is less rapid in providing a number of plants in a

short time than working on stocks. With new kinds I fear that we must for some time put up with the inconvenience, but the sooner that can be remedied the better, as I expect that in a few years the majority of Roses will be grown on their own roots where the soil is suitable; and when good old varieties become so well known and proved as to be preferred to untried new ones, we may expect to find the class of Roses here spoken of as plentiful as beds of Tom Thumb, Golden Climber, and other old favourite Geraniums, which retain their place in spite of the scores of newer kinds said to surpass them. Roses, however, are far from being well known, or rather many of them have not been tried, in the way I recommend, until that be done, and while the demand always runs in the direction of new kinds, we must expect to have to contend against briar and Manetti suckers, and the other evils that follow in their train.

Although recommending Roses to be grown more extensively on their own roots, I am by no means certain that success will in all cases attend the experiment, but even the want of it enables us to come to the proper conclusion in the matter. On this head I should like Mr. Radclyffe to again enlighten us; and if he will say what success he has had with the best class of Tea Roses on their own roots I shall be obliged, for I confess that my experience in this direction is very limited. Other growers will, perhaps, be kind enough also to state their experience; for if Roses can be made to do well without the clumsy process of being supported by something else, they will be all the better servants.—J. ROBINSON.

MORE ABOUT POTATOES.

"Arrah, then, boys, wouldn't ye be content," I once knew an agent of Lord Angelsea's C— properly saying to some of the "finest pisantry in the world," "with pace and plinty staring you in the face, and the harings rowling agin the shores? So here's Praties galore and Erin-go-bragh!" Now, that same toast I can cordially re-echo; notwithstanding Fenianism overshadowing the land, I love ould Ireland and many an one in her; and I can also cordially say I like "Praties galore," only let the plenty not be obtained at the expense of quality.

Having a very decided opinion that no Potato except a Kidney is fit food for a connoisseur for all round Potatoes have, I think, more or less of that earthy flavour which to my mind destroys the delicacy of this useful esculent—I determined this year to try whether I could not begin, soon, and end with some sort of Kidney; and in accordance with the recommendation of, I think, "Upwards and Onwards," I obtained from Messrs. Sutton & Sons, Reading, and so from a source on which I could rely, good sound seed of the following:—

- | | |
|---------------------------|----------------------|
| 1. Sutton's Racehorse, | 4. Lapstone, |
| 2. Myatt's Ashleaf, | 5. King of Potatoes, |
| 3. Rivers' Royal Ashleaf, | |

and now give my experience of them. I should say that I do not think my garden is a favourable one for the growth of Potatoes. The soil is very rich, and hence they are apt to be waxy—a thing which I abominate. I must also add that the disease attacked Potatoes with a virulence in this neighbourhood that I have not seen for years, whole fields belonging to a neighbour of mine being left uncut, as they were not worth the trouble or expense of taking up.

I intended the Lapstone for a main crop, hoping that they would last me until late in the spring, when No. 5 would have helped me on. I hoped, till the new Potatoes were at hand, Sutton's Racehorse I found to be a few days earlier than the Ashleaf, but I do not think so good, and I should prefer relying on the latter for my first crop for another year. Of the Ashleaf I need say nothing; it suited my garden, and is a good and delicate flavoured Potato. Rivers's Ashleaf disappointed me. I had heard many speak so well of it, that I quite hoped that it would prove a valuable second Potato; but with me it did not do so. It was waxy—deficient, therefore, in flavour, and not a good cropper. The Lapstone is a gem. Doubtless it is a delicate Potato and liable to the attacks of the disease more than others, but what a delicious Potato it is! Nothing could have been more beautiful than the even graceful growth of the haulm; and nothing more woful than to see the "rind-pest" attacking it, the skins becoming spotted, and then the stalks rotting. When I dug the Lapstones out there was a large quantity of diseased ones, but they were unlike any diseased Potatoes I had ever seen. Instead of that brown dry spot which so soon spreads over the entire root, the whole tissue

seemed to be destroyed, and the tuber to be one mass of mortified matter. When they were hoised I found them rapidly going. I then took some quicklime, slaked it, and shook it over them, and from that time had no more deaths; whether owing to the lime or not I cannot say, all I know is the Potatoes kept well. This is to my mind the premier Potato. I know none to equal it for flavour. It steams well, and is very floury; and although I lost so much of it last year, I shall rely on it for my main crop for next season.

With the King of Potatoes I was also greatly disappointed. I have tried it both baked and steamed; but there is a very disagreeable sweet flavour about it—at least, and this is all I can say, when grown in my garden. The soil may not suit it, and there are things we can only gain by experience. This is a point one cannot too much insist on—that soil, situation, and climate do exercise a very material effect on fruits, roots, and flowers, and my experience may not be that of many of your readers.

When at Gloucester in the autumn Messrs. Wheeler, the well-known seed merchants, showed me, and, indeed, gave me to eat, a Potato called Milky White—a Kidney, of very excellent quality, floury, and beautifully white. They also spoke very highly of one which I see advertised extensively, called Mona's Pride, an early Ashleaf variety.

As to cooking Potatoes, I thoroughly and entirely endorse what my friend Mr. Radclyffe says, that the only way to cook them is to steam them, and to send them up to table with their jackets on. Poor Power, I remember, in my younger days used to say, when detailing his adventures in England, "Them's a barbarous people—they peels their praties afore they biles them!" And how any one can imagine a Potato can be properly dressed, or the flavour properly secured, by adopting such a method I cannot say. Let no one think it a very vulgar way to send them up to table. I have seen them so at some of the best houses not only in Ireland but in England.

As I have mentioned Mr. Radclyffe's name, I am sure his many friends will be glad to learn that he has found a resting place. He has obtained a house not very far from Blandford, belonging to Lord Rivers. It is at a place called Fitzpaine Okeford (we shall have to drop the first when we come to write about him); the land is of first-rate quality, very different from Rushton, and consists of four acres and a quarter, including two gardens, an orchard, and a field of fine grass land, a greenhouse, but no walls. The latter want I dare say can be remedied. The late tenant was a good gardener, and very fond of Strawberry-growing. The nearest station is Shillingstone, about a mile and a half distant. Won't there be a fitting there by-and-by when all the new Roses from Rawston find their way there! and shall we not hear, if our lives are spared, something from this said garden! And I am sure the hearty wish of all rosarians and fragarians will be, Long may he live to enjoy the *otium cum dignitate*.

And now as to this year. I have determined to try, if possible, to obtain a small piece of ground where there is not so much rich stuff, and to give Potatoes a fair trial. Mr. Radclyffe has sent me a few Red Ashleaves, Salmon Kidney, and the Hybrid Lapstone. I have also the Milky White and Mona's Pride, and may possibly try a few others; but if one can hit upon four good kinds—early, second early, main crop, and late, I do not see what we need more. The Salmon Kidney which Mr. Radclyffe sent me is very like one that used to be grown in this neighbourhood and called the Denne Hill Kidney, or "Parson's Kidney." I shall look to the Lapstone for my main crop. Regarding Paterson's Potatoes, I must fully endorse Mr. Whiting's views of them in a contemporary—they are fit for the field, good for pigs, but I do not like them for eating, being coarse and earthy. The same I would say of the Fluke and its allies. It is a handsome Potato, boils well, very little waste, but there is no flavour in it. It does capitally for London eating-houses, but I should be thankful to have something better at the time when it comes in. The best way to treat it is to make *pommes de terre frites* of it:—Cut it in thin slices raw, and then throw them into boiling oil or lard, and fry them of a light brown, as one gets them at Paris restaurants.

I have had my little say, and can only end with the agent's toasts, "Praties galore!" and "Erin-go-bragh!"—D., Deal.

TESTIMONIAL TO THE REV. S. REYNOLDS HOLE.—We have been requested to state that the subscription list must shortly close.

ORCHID CULTURE IN COOL TEMPERATURES.

I AM extremely obliged to Mr. Keane for his reply to my note on the above subject. I have had the pleasure of visiting the establishments referred to, and have long been convinced "that some kinds delight in a low temperature." I am also convinced that their number is very limited, I mean the number of genera. This being the case, would it not be well to state the kinds that require cool treatment, as I need hardly remark that the word Orchid is one of very wide import?

An apology is due from me to Mr. Keane for having made any remarks on the subject in the columns of THE JOURNAL OF HORTICULTURE, but I have done so for the following reasons:—First, I have tested the experiment and have failed; secondly, I know others who have done likewise and have lost their plants; thirdly, I know others who have small collections, and, probably, small means, who are strongly inclined to adopt the cool system in consequence of the saving in fuel—now, many of these collections have been slowly acquired, and are, perhaps, the only hobby of the owners; therefore, it would be a great pity if they were lost to them; and fourthly, because I think that to keep an Orchid-house containing *Vandas*, *Aërides*, *Saccelabiums*, &c., at a temperature of 55° during winter, as recommended, is dangerous and calculated to lead to unsatisfactory if not fatal results.—B. FINDLAY, *Botanical Gardens, Manchester.*

[The enclosed list of Orchids was obtained principally from Mr. Pileher, who has the management of Mr. Rucker's celebrated collection. He has them separated into three collections—namely, those requiring high, intermediate, and cool temperatures. Those requiring cool temperatures he has no objection to see at 45° at night, and in severe weather as low as 40°, with a rise in the day by sun heat to 60° or 70°.

At Knypersey Hall, near Congleton, the seat of J. Bateman, Esq., even more than twenty years ago was a large greenhouse which contained a plant of *Dendrobium Wallichianum*, also *Cyrtopodium speciosissimum* and *Calanthe discolor*, all in a fine healthy condition, and which were stated to be grown there during the winter; the temperature of the house was about 45°. Also, a vinery nearly filled with Orchidaceous plants—such as *Lælia superbiens*, very strongly grown; fine plants of *Dendrobium pulchellum* and *Barkeria Lindleyana*, *Stanhopea aurea*, *Oncidium bicallosum*, *Odontoglossum pulchellum*, and a remarkably strong and healthy mass of *O. grande*, which was constantly kept there and bloomed annually. There were many other smaller plants equally healthy. The temperature of this house was 50° in the daytime.

In another house were South American Orchids. Here the temperature was about 65°, and the atmosphere abounded in moisture. In a large span-roofed house with double glazing were the Indian Orchids. This erection was filled chiefly with *Stanhopeas*, *Aërides*, *Vandas*, and *Saccelabiums*. The temperature of this house ranged from 75° to 80°. The visit was made in April, 1844.—W. KEANE.

CHAUMONTEL PEARS IN JERSEY.

I was informed the other day by one who had just returned from Jersey, that the famous Pears of that island are grown upon espaliers at 1 foot distance from the walls. May I ask the reason of this custom?—WYESIDE.

[The Chaumontel Pear is grown on walls in the Channel Islands. South-west is probably the best aspect. Jersey has

a superior fruit-climate, as it slopes to the south, while Guernsey slopes to the north; but in both islands walls are considered necessary to bring this Pear to perfection. Size is obtained by summer-mulchings of seaweed, and repeated waterings; shape, by removing all but the centre blossom. This is thought to produce long-shaped Pears—by far the most saleable. Found Pears are sold at £5 the hundred, while half-pound Pears rarely bring one quarter of that sum. To obtain the largest Pears very few must be left on the tree. Espaliers removed from the wall are not considered first-rate.]

INTERNATIONAL HORTICULTURAL EXHIBITION AND CONGRESS OF 1866.

We are much gratified by being able to announce, that at a meeting of the Corporation of the City of London, held on Thursday last, it was unanimously resolved to grant the use of the Guildhall for a banquet to be given to the foreign visitors to the International Horticultural Exhibition and Botanical Congress, to be held in London on the 22nd of May next. We believe this is the first occasion on which the Guildhall of the City of London has been granted for a banquet which has not been connected with the Corporation.

MUSHROOMS OUT OF DOORS, AND FORCING IN POTS.

SOME Asparagus-beds, made in the autumn of 1864 in the ordinary way, produced during last August, September, and October, a good supply of Mushrooms; and in the beginning of November, thinking all was over, the beds were cleared, and a top-dressing of well-rotted manure given. To my surprise, from that time to the present I have frequently gathered a dish of fine Mushrooms, and twice since Christmas-day—viz., on the 28th of December and 4th of January, which is quite a novelty to me, and at the same time very acceptable, as a bed under cover has not come on so rapidly as it might.

The soil is of a sharp peaty nature, resting on gravel, which I have no doubt had something to do with such an unusual production in this wet season.—S. ROGERS, *Hants.*

P.S.—I have filled some 15-inch pots with rather fresh horse-droppings, spawned, soiled, and placed them in a heat of about 60°, with an inverted pot over them. Now, to save time, I should be glad if you could recommend me any other way with pots.

[No doubt your dry gravelly subsoil and the mildness of the season had something to do with the production of Mushrooms on an Asparagus-bed in the beginning of 1866, the bed being made in the autumn of 1864. Most likely the spawn had continued to run in the dung that had been used in making the Asparagus-bed, and must have withstood the frost of last winter, or been deep enough then to be beyond its reach. It was stated some time ago in "Doings of the Last Week," that a Mushroom-bed that had produced in an open shed in the summer of 1864, and which it was considered had done bearing, was left accidentally all the winter, protected from nothing but wet, and in the spring of 1865 it began producing again; and when it was watered and a little hay put over it, it produced heavily again. This bed, altogether, was not more than 10 inches deep, and the dryness of the surface was the only circumstance that would prevent the bed being well frosted. In fact, we do not know the amount of frost that the spawn will stand with impunity; but the frost can never penetrate below a covering of grass pasture to anything like the depth it would do in exposed soil. Most likely the Asparagus-bed, too, had some dressing last winter. The fact, at any rate, is worth recording, though we have had several letters about Mushrooms being found in pastures up to Christmas this season. One other important point we should like to know about afterwards, and that is the result of the Mushrooms appearing amongst the Asparagus. We should not be surprised if the spawn injured the Asparagus. Some funguses make sad havoc with other crops; and therefore, however useful the Mushrooms may have proved, they may eventually prove quite the contrary. All such facts are very useful, as they often lead to fresh experiments and results.

We presume that you have managed the pots all right. They must be watched for spawning the same as a bed, only a pot if filled with fresh droppings soon comes to the right heat. Keep the heat rather below 60° than above it. Beware that

the empty pot placed over the other does not make the surface too hot. Whenever the spawn begins to run the temperature will rise. In practice, a little surfacing of hay before the Mushrooms appeared would be as good as the inverted pots. ERS.

IRELINE HERBSTH FOR DINNER TABLE DECORATION.

Much has been said of late both for and against this plant. Some are strongly in favour of it, and are very sanguine as to its future; others are—much the other way, and condemn the plant altogether. I shall certainly not now class myself with the latter, for the more I see of the Iresine the better I like it. If it prove a failure as a bedding plant after it has had a fair trial next summer, there is another important purpose for which it will be used, and for which it cannot fail to be appreciated—well-grown plants cannot be surpassed for drawing-room and dinner-table decoration.

The way to grow plants for table-decoration in the winter is to strike cuttings early in August. As soon as they are struck they should be potted off in large 60-pots, and placed in a temperature of 65° or 70°, and as near the glass as possible; this will cause them to grow stocky. Care must be taken not to put them too closely together; they should be placed so that the air may circulate freely amongst them and in positions where they will receive the same amount of light on all sides. A suspended shelf is a good position. Thus placed, the plants will grow regularly all round. The top must not be pinched out, but the side shoots should be stopped after they have made the second pair of leaves.

As soon as the plants have grown to a height of 18 inches, they should be kept rather dry. They will by this time be furnished with side shoots from top to bottom. They should then be shaken out and repotted in 48-sized pots; the most suitable soil is a mixture of peat, leaf soil, loam, and silver sand, in equal proportions. After potting, the plants should be placed in a similar position to that which they previously occupied, and where they will soon fill the pots with roots. All the side shoots must be stopped as soon as they have fairly made a pair of leaves above the joint at which they were stopped before.

When the plants are well established they should be supplied about twice a-week with weak guano water; this will bring out the colour of the leaf in great perfection. There will be no necessity for putting the plants into larger pots than those named above. If the pots are larger than 41 or 5 inches in diameter the plants often have to be turned out of the pots in order to make them go into gold or silver cups, and the roots, consequently, are frequently very much injured, and the appearance of the plant is then soon spoilt.

The plants should be stopped as above directed till about the last week in September; after that time all the shoots may be allowed to grow. By the end of October the plants will be perfect models, and the colour of the leaf will far surpass anything we have for dinner-table decoration. Small plants, if grown as described above, when mixed with any light-foliaged plants, such as *Centaurea candidissima*, and *Ferns*, Mosses, &c., are very chaste and beautiful for stands in drawing-rooms and vestibules; and large drawing-room vases arranged as follows would produce a very neat and beautiful effect:—Place one large plant of Iresine in the centre, then a ring of small plants of *Centaurea candidissima* and Iresine alternately, all round. If the vase is white, and it is large enough, a margin of *Adiantum cucullatum*, or any other dwarf and graceful Fern, would make it perfect. The vase, however, in the daytime should be placed between the line of vision and the light, the colours would then be seen to perfection.

In the selection of cuttings care must be taken to take them only from plants that are perfectly healthy and in a free-growing state, and all the leaves should be perfect as to shape, &c., as they will all be retained by the plant from the time that it is a cutting until it is full-grown.—J. WILLS.

RAINFALL AT ARDDARROCH, DUMBARTON-SHIRE.

I SEND you an account of the rainfall here for the last twelve years. The gauge is 80 feet above the level of the sea. The climate here is very mild; we very seldom have any frost, and evergreens thrive remarkably well, especially *Rhododendrons*. Seedlings of these grow so freely among the plantations, that

we often require to hoe them up in our wood walks; but it requires great care to keep Grapes that are ripened in August hanging till the month of December.

—W. MA, Gardener.

CULTURE OF GOLDEN VARIETATED GERANIUMS.

I QUOTE agree with what Mr. Reid has said in regard to the disappointment that many have met with in the growth of these; also in regard to the reciprocity between root and branch, that there is a deficiency of fibrous roots as compared with other bedding Geraniums. I find, however, that if they receive the following treatment they will have the required amount of roots and branches like other varieties, and at present I have a stock which, I am sure, cannot be surpassed for health and vigour.

The following is my mode of treatment:—When the cuttings are taken off, say about the beginning of September, they are inserted in a cold pit in a compost of two parts of loam that has been used for growing Melons, one part of old Mushroom manure, and one part made up of silver sand and leaf mould. When the cuttings have been put in they are well watered to settle the soil round them; the lights are then drawn on, and no air given let the sun be ever so bright. When the cuttings become dry, which they will do first at the back of the pit, or frame, give water, but not overhead, as Geraniums are not often benefited by such waterings.

As soon as the cuttings are rooted, which they will be in the course of five weeks, they ought to have a little air for eight or ten days, when potting should be commenced without delay. In doing this use large 60-pots and the same compost as before, with the exception of adding a little more sand. After potting, if there is a frame from which Melons have just been cleared out, no place could be better adapted for them, as there will be a gentle bottom heat. By keeping close for six or eight days growth will recommence, when air ought to be given very gently at first, but the amount should be gradually increased till the young plants are fully exposed. There they may be kept till the nights become too cold, when they should be placed near the glass in a house where a little heat is maintained throughout the winter, for they are very impatient of cold and damp, and when exposed to such conditions soon lose their foliage and perish, or become useless.

In spring, say about the end of March, I take them out of the houses where they have been kept growing from the time they were struck. They are now removed into pits or frames according to circumstances, and plunged in old Mushroom manure to about 1 inch above the rims of the pots. Thus they remain till planting-out time, when they are found to have rooted over the rim of the pot into the manure. If carefully removed to the beds a portion of the manure is carried along with each plant, and the plants begin to root at once and experience no check.

Treated as above, the plants at bedding-out time are found to be as fine as any of the strong-growing varieties. I may mention that I have tried other plans, but none seems to succeed so well and give so much satisfaction. The plants are generally the admiration of all who see them during the summer months.

The tricolor-leaved varieties I treat in the same manner, but my experience is more limited with them but equally satisfactory.—JAMES STEWART, *Nucham Park*.

PRIMULA SINENSIS.—The finest and richest coloured Chinese Primroses we have yet seen are those raised by Messrs. Cutbush, Highgate Nurseries.

MUSA CAVENDISHII CULTURE.

ALLOW me space to say a word or two for a favourite of mine, the *Musa*, or Plantain Tree, which, I think, would be a universal favourite were it better known. It is well worth growing for its beautiful foliage as a stove plant, as well as for its fruit, and Mr. Gibson, of Battersea Park, has shown us its capabilities as an out-door ornamental plant.

The species cultivated by me, *Musa Cavendishii*, is, I think, the most tractable of the family, as well for fruiting as for growing, and from my own experience of it, I will endeavour to give a few hints as to its successful fruiting. Procure a sucker—say in March, as it will then have the summer before it. Supposing the sucker to be 3 or 4 inches in height, pot it in a middling-sized pot—say a 16 or 24, in a compost of peat, loam, and sand, well draining the pot, and potting rather lightly. Do not give much water till the roots have reached the sides of the pot, when the plant should be watered freely. Let it remain in the same pot, and in an ordinary stove temperature, for six or eight weeks, by which time, if all go well, it will be a good strong plant of 2 or 3 feet in height, with well-developed foliage.

The plant is then ready for the fruiting-pot, the size of which with me is 3 feet in diameter at the top, and about 2 feet deep. The pot should be placed where it is intended to grow the plant, and drained with 6 inches deep of oyster shells, charcoal, and crushed bones. Placing the young plant upon the drainage without disturbing the ball more than can be avoided, fill in at the sides of the fruiting-pot with strong yellow loam and rotten tan, which compost I find most suitable for fruiting. The plant will now be ready to be pushed along, and should receive rather liberal doses of liquid manure twice a week—say 4 gallons each time, and the same quantity of clear water in the week as well. This treatment and a temperature of about 80°, not shading more than can be avoided, should by September produce a plant 8 or 10 feet in height, and with its beautiful foliage it will have a very good appearance in the stove, for which it is an excellent centre plant. By keeping it dry for a week or two at this time it will throw up its flower-spike, which is a beautiful object, and as it continues to grow the rows of fruit will appear overlaying each other. When the first row of fruit is half-developed the watering should be recommenced as freely as ever, and with ordinary success there will be by Christmas a bunch of fruit as long as the arm, or thereabouts, and weighing 18 or 24 lbs, which should be ripe about the end of February or beginning of March, making a very unique addition to the dessert. I have a plant now growing, about 9 feet high, with a stem measuring 2 feet in circumference.—W. C.

REMINISCENCES OF TROPICAL FRUITS.

SOME years have now elapsed since I had occasion to pass a lengthened period in various tropical countries; but the vivid recollections impressed on my mind concerning many of the fruits will never be effaced.

I will first notice *ARTOCARPUS INCSA*, or Bread-fruit, which attains the height of 30 feet in the South Sea Islands. It is a beautiful tree at every stage of its growth, and easy of cultivation in our stoves. It is of great value to the natives of the South Sea Islands, and forms a considerable article of food. The fruit is about the size of a child's head, and round; the outer covering or rind is very hard, and contains a pulpy substance. The fruit is generally cooked in native ovens, and when prepared has the appearance of new bread, and in taste comes the nearest of anything that I know to badly leavened bread; a peculiar acid predominating, and a few strong fibres which traverse the pulp, are an objection; at the same time I have eaten many worse vegetables.

ARTOCARPUS INTEGRI-FOLIA is another noble member of this genus, popularly known as the *Jaca* or *Jack-fruit*. It is very ornamental in the tropics, but as it attains a height of 50 or 60 feet, I fear it will be seldom seen in this country. The fruit is very curious, being of the size of a small Pine Apple, with the stalk at the small end. The skin is rough, orange yellow, filled with an offensive pulp containing a number of seeds. The fruit generally appears on short foot-stalks, which protrude from the main stem or large branches, and is only eaten by the black population.

NELITRIS JAMBOSELLA is an interesting plant from the Society Islands, attaining a height of from 7 to 10 feet. It belongs to the order Myrtaceae, and is very nearly allied to the genus

Psidium, and by many would be taken for a *Guava*, the only difference is, that the fruit or berry is not partitioned. It is very refreshing, and I think worthy of cultivation.

ISOCARPUS EDULIS comes from the same quarter, and is frequently called the *Otaheite Chestnut*. The fruit has a very curious fibrous covering, and may be considered more in the light of a curiosity than as being of use. The plant fruits in a young state, and is worthy of a trial in our stoves.

FREYCINETIA BANKSI.—This is a very curious plant, having leaves much like a long, narrow-leaved Pine Apple or *Pandanus*, and fruit much in the form of *Monstera deliciosa*, but smaller, and of a fine pink colour; from it is made a very excellent jelly. I believe that it is only found in New Zealand, where it ascends the highest trees by its creeping, rooted stem, and adds a beauty to the trees not their own. While speaking of New Zealand, there is a beautiful dwarf Palm, which produces large clusters of scarlet berries (*Areca sapida*), worthy a place in the most select collection.

DIOSPYROS MABOLA, or Date Plum, of the Philippine Isles, produces a fruit in size and form like a medium-sized Peach, and *D. Kaki*, of Japan, produces a fruit much like an Apricot; but not having seen it in bearing I know very little about it. The fruits of both are very austere before maturity, and require keeping until in a state of incipient decay, like our Medlars, before being sent to table.

LUCUMA MAMMOSA, or Marmalade Tree of South America, is very beautiful either when in fruit or not. The fruit is filled with a pulp like Quince marmalade, and very good, but it is not equal to that of a species I met with in Peru and Chili, called

L. DELICIOSA.—This plant has larger and broader leaves, and larger fruit than *L. mammosa*. I once saw plants of it in the nursery of Messrs. Backhouse & Son, York.

GRIS CAULIFLORA, or Anchovy Pear, a native of Jamaica, and one of our most showy stove plants in or out of flower. The ripe fruit is of little or no value for the dessert, but that which is unripe makes an excellent pickle.

MAMMEA AMERICANA, and the various species of *Nanthochymus*, also belong to the same order as *Grias*; and as the whole of them have showy flowers and good foliage, all are worthy of cultivation, even if fruit is not an object.

Two species of *NANTHOCHYMUS*—viz., *X. ovalifolius*, and *X. pictorius*, succeed with less heat than the others, and will do well in a conservatory. *X. dulcis* is the best.

ERIOBOTRYA JAPONICA, or Loquat, is one of the easiest of tropical fruits to fruit in our stoves, at the same time many make sorry work with it, and say it is shy. I remember seeing a large plant on the back of one of the old houses in the Glasnevin Botanic Garden, which had been muddled for years, and never fruited, and I have seen it fruit on the open wall in the west of Scotland without protection. We appear to have only one variety in cultivation in this country; many with local names are known where it is much cultivated. There is a variety with large white fruit, very ornamental; also, one with much smaller fruit of a dark orange brown colour, and excellent in flavour. This is *RADDII*, *Peterborough*.

(To be continued.)

NOTES ON PEAR CULTURE.

IN Mr. Rivers's last catalogue of fruit trees there are some remarks on various fruits and their cultivation so worthy of attention on the part of all fruit-growers, that I shall be glad if you will give them a place in your widely-read Journal, with a view to elicit the experience of cultivators, particularly of Pears, in all parts of the kingdom. He says, Pears "differ in their adaptation to soils and climates," and "we have yet much to learn on this subject. Pears differ so much in quality with very slight variations of soil and climate, that much allowance must be made" (for difference of opinion). Again: "double-grafting of Pears will ultimately have a great effect on their culture in gardens, they seem always to make healthy and prolific trees; it must not, however, be concluded that to graft a free-growing Pear on the quince, and then to re-graft it with the desired sort, will always answer, some kinds require the stock belonging to their race; this can only be found out by the clever cultivator." "When this scientific method of cultivating Pears is fully understood, those who introduced the culture of Pears on the quince stock will have thanks instead of the usual deep grumble of the English gardener."

Now, I only cultivate fruit in a small way, yet every step I take, and every fragment of experience I pick up, serves to convince me of the soundness of these opinions; and with the view of eliciting the experience of others, I will relate some of my own observations, not only as to the soils and climates suited to the various sorts of Pears, but also to their treatment after being gathered.

For instance: Mr. Rivers classes the *Burré de Capiaumont* among the baking and stewing Pears. Here, besides being on an east wall one of the most productive Pears in my collection, when gathered before it is too ripe and placed in a warm room (not under 60° Fahrenheit) as soon as gathered, it is rich, melting, and excellent. It does not, however, keep more than a few days after arriving at maturity. As I have said before in this Journal, it was quite worthless with me as a standard, even in the last fine season.

The *Burré de Rance* growing here in a stiff clay little, if any, better than puddle, and double-worked on the quince, is of admirable quality; whilst in the rich alluviums of Wharfedale, into which district I sent some to a friend, this variety is utterly worthless. I think Mr. Pearson, of the Chilwell Nurseries, confirms this opinion, as he says this variety is only of good quality on the clay.

Again: the *Dunmore* here is excellent when double-worked on the quince; on the Pear, both on the walls and as a standard, it is of very indifferent quality, although it bears well.

Again: Williams's *Bon Chrétien*, which seems almost a standard of quality in the London markets, is here utterly worthless. Of course some allowance must be made for difference of taste; but admitting this, I can scarcely suppose that any good judge of fruit would be satisfied with the quality of Williams's *Bon Chrétien* as grown here; and the *Glou Moreau* must be classed in the same list.

Mr. Rivers has somewhere said that every fruit has its own peculiar season, when its excellencies are more perfectly developed than in other years apparently more genial. I allude to this remark because my *Seckle Pears* and the *Louise Bonne* of Jersey, grown on an east wall, were of better quality in the cold and wet year of 1860 than they have been either before or since.

I had written so far when I received the Journal of the 9th inst. containing an article on the growth of bush Pear trees on quince stocks in the Yorkshire hills, which is exactly the sort of communication I want to elicit from your correspondents. Your correspondent "C. I. M." has, however, omitted two points, which I hope he will add to his next communication, these are, the sort of soil in which he grows his Pears, and the elevation of his garden above the sea. I, like him, find the *Burré Superfin* a shy bearer even on an east wall, and the quality with me is by no means what I had hoped to find it.

The *Hessle* bears well with me, and the quality is much improved, judging from one example, by being grafted on the Thorn; but, unfortunately, the tree is then only short-lived. I have not tried it double-worked.

Mr. Rivers, some time ago, said that a dwarfing stock for Plums had not been met with hitherto: has the *Damson* or the *Sloe* been tried, double-worked? A friend of mine budded a *Green Gage* on the *Sloe*, many years since, but I do not think that any increase of fertility resulted from the experiment.

I hope that the letter of "C. I. M." may elicit many other communications of the same kind, which will, I think, greatly increase our knowledge of Pear-growing.—T. G.

MUSA VITATA FRUITING.

Will you inform me, has *Musa vittata* fruited in cultivation? We have a noble plant, 14 feet high, with a fine cluster of fruit, which is beautifully variegated.—J. SAYERS, *Gardener to Thos. Turley, Esq., Blackrock, Co. Dublin.*

I have made several inquiries, but cannot find that *Musa vittata* has fruited before in this country; still, if my memory does not deceive me, I have seen somewhere an account of its having done so. However, be this as it may, it is very desirable that the fruit should be well ripened; and as *Musa vittata* is only a beautiful variety of the ordinary fruiting sort, I see no reason why this should not be accomplished.

There is no tropical fruit grown in England the ripening of which is so little understood as the *Musa* or *Banana*. I have tasted, I may say without exaggeration, hundreds of the fruit ripened in this country, and out of all that number I only

remember four that were fit for anything; the rest were either completely flavourless, or tasted like very over-ripe Pears. Now this is not as it should be. The *Banana* may be ripened here as well as abroad with a little trouble; and as I have been very successful in giving the fruit a good flavour I will just mention a few of the principal points.

In the first place, then, from the time the fruit forms until it begins to ripen the plant should be plentifully supplied with weak liquid manure as well as water, and a high moist temperature should be kept up in order to swell the fruit to a handsome size. Little air should be given by day, but considerably more by night, and the temperature should then always be from 10° to 15° lower. My day temperature without sun during this period was 80°, allowing a rise of 10° by sun heat.

Secondly. The plants, particularly the variegated ones, should never be watered over their foliage by day, as it injures their beauty and is not good for them. My plan was, always the last thing at night to give the foliage a thorough syringing and let the water stand on the leaves all night. This, strange as it may appear, I found wonderfully beneficial to the plants. As the morning advanced of course they became dry, and were not again touched even in the hottest weather until night. I believe this to be a great secret of success.

Thirdly. When the fruit begins to ripen, which may be known by its not swelling any more, all water must be withheld from the roots, and the air kept hot and dry. This is most important, for upon it will depend the flavour of the fruit. The temperature may now range as high as 90°, allowing a little more by sun heat, and no air must be given by day, although it should be given plentifully by night. Every evening the floors, pipes, &c., may be well syringed, and the plants themselves very slightly; but as I said before, no water should touch the roots until the fruit is ripe, unless they flag very much. By these means, and by giving all the light possible, the *Musas* may be ripened with an excellent flavour in England, and the fruit is then a melting and most delicious one.—J. H.]

VARIOUS.

ESSEX RIVAL PEA.—At page 262 of last Volume "NICKERBO" asked for information of Mr. Eley as to the parentage of Essex Rival Pea. If it is new there could not be much difficulty in the raiser giving the parentage; but how comes it that the new Pea Essex Rival of 1865 is synonymous with a Pea which has been grown for years in Nottinghamshire and Leicestershire, and is now advertised by a midland house at one-third less than by Mr. Eley himself? and it could be sold for still less. It may be a good Pea, but it is an old one to some persons. Why have these double names to seeds and plants?

FENNIAN SYSTEM OF USING SEWAGE.—Many may not like the trouble or have the opportunity of heating sewage as Mr. Fenn has done; permit me, therefore, to state for the benefit of your readers a case in my own experience. About the year 1852 or 1853 I took charge of a garden near Bristol for a short time; it was in the spring, and there was a scarcity of Lettuce, and, having some standing under a south and south-east wall, I was anxious to bring it on for use. There was at the stable-yard a large tank which took all the drainage from the stables, cow-sheds, and piggeries, and the washings of the fowl-houses: the stable was on the other side of the mansion, and, to convey the liquid manure, we had only the garden engine, and the wheeling had to be done early in the morning, as we were robbing the fields, so said the "great authority." Well, I used to take the engine and use it myself, lest any of the men should fall into disgrace, and pumped this sewage well into the soil round the Lettuce, and most assuredly with benefit to that crop. The ground after the application was always raked over to check evaporation as much as possible, but on this wall were some Peach trees which had the "curl," and were infested with millions of green fly. I therefore tried the experiment of pumping on them, giving them a good washing, and, after three or four dressings, there was unmistakable evidence of the utility of the liquid: the trees rallied and grew, carried a fine crop, and had good shining foliage. Since then, whenever I could obtain it, I have always used sewage for green fly, and never, that I remember, have lost or injured a plant by it. Use it as it comes from the tank, but not while the sun is on the trees at mid-day.

VARIATION AND DISEASE.—Some time since we had a discussion on "Variation, is it Disease?" Have any of your correspondents been able, by observations, to throw any more

light upon the subject? I do not recollect to have seen so many sports and variegations in any year in my experience—variegations in Coniferae, hardy shrubs, Blackberries, and a tricolor *à la* Mrs. Pollock, but I doubt its coming so next year; variegations in Nettles, Dandelion, Chickweed, and Groundsel, Golden and Silver Arbor Vita, Silver Cupressus Lawsoniana, Golden Wellingtonia, &c., and even in Peas, Radishes, and Turnips. What can be the cause? for these variegated forms have come under my notice in various places—Kent, Surrey, Sussex, Warwick, Gloucester, Leicester, and, to controvert the theory that variegation is always accompanied by diminished growth, some of these sports have been stronger than the green-leaved species. I should be glad of the opinions of some more accurate observer than—NICKERBOB.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

RHODODENDRON HODGSONI (Mr. Hodgson's Rhododendron).—*Nat. ord.*, Ericaceæ. *Limn.*, Decandria Monogynia. "One of the noblest of the grand series of Rhododendrons that adorn the Eastern Himalayan Mountains," at elevations of 10-12,000 feet. Flowers purplish pink.—(*Bot. Mag.*, t. 5552.)

LÆLIA GRANDIS (Large-flowered Lælia).—*Nat. ord.*, Orchidaceæ. *Limn.*, Gynandria Monandria. Re-introduced from Bahia, by Messrs. Hugh Low & Co., Clapton Nursery. Sepals nanken; lip purple-veined on white ground.—(*Ibid.*, t. 5553.)

BEGONIA BACCATA (Berried Begonia).—*Nat. ord.*, Begoniaceæ. *Limn.*, Monœcia Polyandria. Native of Bight of Benin and Island of St. Thomas. Flowers white.—(*Ibid.*, t. 5554.)

SPARAXIS PULCHERRIMA (Most beautiful Sparaxis).—*Nat. ord.*, Iridaceæ. *Limn.*, Triandria Monogynia. "A most lovely Cape bulb," introduced by Messrs. Backhouse, of York. Flowers rich purplish crimson.—(*Ibid.*, t. 5555.)

EPIDENDRUM MYRIANTHUM (Many-flowered Epidendrum).—*Nat. ord.*, Orchidaceæ. *Limn.*, Gynandria Monandria. Native of mountains of Guatemala. Flowers lilac.—(*Ibid.*, t. 5556.)

SWAINSONIA MAGNIFICA.—Introduced from Australia by Mr. B. S. Williams, Victoria Nursery, Holloway. Flowers pink, and large.—(*Floral Mag.*, pl. 273.)

CLIANTHUS DAMPieri var. MARGINATA.—We noticed this at page 321 of our last Volume.

NEW STRIPED VERRENAS.—Beautiful, white, variously marked with purple. *Carnation*, white, marked with crimson and pink. *Fascination*, white, marked with crimson and pink.—(*Ibid.*, pl. 275.)

PRIMULA CORFUSOIDES AMENA var. ALBA.—Received by Mr. Veitch from Japan. Flowers, some purplish pink, others French-white.—(*Ibid.*, pl. 276.)

BEURÉ D'ANJOU PEAR.—"The fruit which we now figure under the name of Beuré d'Anjou is not the same as Brown Beuré, of which the same name is a synonyme, but another and a very different variety that was introduced by Mr. Rivers under that name. It is, we are informed, the *Nec Plus Meuris* of the French nurseries, and was received from Messrs. Jamin et Durand, of Bourg-la-Reine, under that name; but it is totally distinct from the *Nec Plus Meuris* of Van Mons. I cannot discover the origin of this variety, and I am, therefore, constrained to adopt the name that has been given to it in the French collections; but it is a most unfortunate one, seeing that it is liable to add to the already great confusion of nomenclature that pomologists have to contend with. It is some years since this excellent Pear was brought to my notice by Mr. Rivers; and I have since found on every occasion that I have met with the fruit, that on account of its handsome appearance as well as the superiority of its flavour, it is a variety of the greatest excellence, or, as Mr. Rivers expresses it to me, 'remarkable for the clearness and beauty of its fruit.' A first-rate Pear, of delicious flavour. Ripe in December."—(*Florist and Pomologist*, v., p. 1.)

TODMORDEN BOTANICAL SOCIETY.—Monday, Jan. 1st. The Secretary read a communication from S. B. Mellor, Esq., of Manchester, in reference to the identity of several interesting Ferns, gathered by Mr. M. in Scotland, North Wales, and Switzerland. A deeply incised form of *Cystopteris fragilis*, from Ben Lawers, had been mistaken by Mr. M., quite pardonably, for the true *Cystopteris alpina* (regia). There are many near approaches found to *C. alpina*. A form in all respects identical with Mr. Mellor's was reported as having been gathered on Snowdon.

ENTOMOLOGICAL SOCIETY'S MEETING.

The first meeting of this Society for the present year was held on the 1st of January, and, as might naturally be expected on such a festival, the members did not muster in their usual numbers. There was a goodly display of donations to the Society's library, including the publications of the Royal and Linnean Societies, the Imperial Societies of St. Petersburg and Moscow, the continuation of the fine works of Sepp on the transformations of European Lepidoptera, of Dural's genera of the Coleoptera of Europe, and of Thomson's Coleoptera of Scandinavia, also Mr. Wollaston's new work on the Coleoptera of the islands of the Atlantic Ocean, &c.

Mr. Samuel Stevens exhibited a large collection of Beetles, Butterflies, and Moths collected with the greatest care in the Himalayan region of India, many of the specimens having been reared from the caterpillar state. Amongst the Butterflies were the very rare *Papilio Mincus*, and several others of the same genus; and among the Beetles, *Buprestis Buquetii*, *Dynastes Hardwickii*, and some fine *Lucanida*.

Mr. Hewitson contributed a memoir containing descriptions of twenty-five new species of Hesperidian Butterflies; and the President, a memoir on the species of Longicorn Beetles (fifty-three in number), collected near Santa Marta in Venezuela by the late Mr. Bonchard, about twenty of which had proved to be new to science.

Professor Westwood read a communication which he had received from M. Suellen van Vollenhoven of Leyden, giving an account of the peculiarities which had been observed in Holland during the past year in the appearance and development of various species of insects.

Mr. MacLachlan read some further notes on the occurrence of insects of the genus *Stenophylax*, belonging to the family Phryganeidae, in deep ice caves in Switzerland. In some instances the insects were found in the most distant and darkest parts of the caverns, especially in one on the road to Chamounix.

Mr. Bates gave some account of the proceedings of Mr. Bartlet, who had gone on a zoological tour to the shores of the Uraly in the foot of the eastern side of the Andes. He had been successful in obtaining large numbers of mammalia, birds, fishes, and especially of insects. His collections had been despatched to this country, and might be expected to arrive in a very short time.

A GARDENING PILGRIM'S PROGRESS.

"W. E. J." tells us that a boy's first duties in a garden are to wash pots, attend to the fires, &c., for the first twelve months, and, in most cases, he is right; but it happened to be the reverse with me. I had to commence my career in the kitchen garden, shrubberies, &c., for the first two years, then I was promoted to the flower garden, and, occasionally, had a job in the houses, in fact, I was a general man for some time. Ultimately, when I succeeded in entering the houses I considered myself making fair progress, because I knew everything in the place, and could do anything that was to be done.

From my first commencement in that garden until I left I was well liked by the gardener, although sometimes I did merit his disapproval, and to give him his due, he was not a bad hand at "blowing up" at such times. Still, his anger soon subsided. During my time there, whatever I had to do I did it as well as I could, and always took a little pride in doing it extra well, but I certainly did like to hear a word of praise now and then. I accustomed myself to think over in the evening what I had done in the course of the day, to see if I had left any tools out, or if I had forgotten to close any of the houses, or cover pits and frames, if necessary; all those duties had a share of my thoughts in the evening, and before I left I saw that all was right. At first I found some difficulty in contracting this habit, but it soon became so strong that I could not leave it off. There is a true old saying that I have often heard when a boy—viz., that "Custom is a second nature." No matter whether a man make a habit of what is good, or what is evil, custom will give him fresh inclinations and capacities for it.

Another axiom is that "A stitch in time spares nine;" consequently a word of advice in time might spare some evil consequences; therefore, I will say to young men, should they have contracted evil habits, Give them up at once, and adopt those that are good, such as studying the various branches of gardening, and although doing so might be disagreeable at first, it will soon become an interesting hobby. But, above all, whatever you have to do in the course of the day, do it with all your might; then, if you are not sufficiently paid for your labour, you will have the pleasure of feeling that you have done your duty, and also advanced a little in knowledge.

From the name signed to this letter the readers of it will at once say that the writer is an Irishman, and they will not be far wrong. Well I remember the day I crossed from Waterford

to Milford Haven. Whether it was because I had a glass or two of whiskey, or the salt water did not agree with my constitution, I do not know; but I kept bobbing my head up and down all the way, and right glad was I when I was on dry land again. I at once made my way by rail to London; and when I arrived at Paddington and found I could not make it my habitation any longer, I walked out, and then I found myself in a dilemma, because my trip to London was only on chance. I had no appointment for any friend to go to, but after a little inquiry I soon found my way to a respectable nurseryman's place, of which I had heard before. I saw him, and he took me on at once, and he soon obtained for me a more suitable place in another nursery. I stayed there until I procured employment from another nurseryman for the purpose of awaiting my chance of obtaining a situation as under-gardener, and I shall always feel grateful to him for his kindness. I was not long in this nursery before he found me employment in a nobleman's place, at fifteen shillings a-week. I was there only nine months when the foreman left, and I had the offer of his place, and I accepted it, as I thought it a good chance to "finish off," as "W. L. J." terms it; but in place of finishing off, I only began to learn, as I found out very soon afterwards; although I knew the names of a good many plants both in and out of doors, also how to manage them well enough, I had, nevertheless, a host of other things to contend with. About the same time some of our more favoured friends in the art began to write about what a gardener ought to know in order to be thoroughly competent to manage a well-kept garden. My heart began to fail; I thought no one with only an ordinary brain could learn so much. What I was to do I did not know, for little as I knew about gardening, I knew less about anything else, and the only course left for me was to persevere and learn as much as I could. I have done so; but I confess I am not finished off yet; but I am thankful for what I have learnt.

Every man has his trials, a gardener has many; but we must always bear in mind that we were sent into this world for the express purpose of undergoing them patiently. It would be well if young men were impressed with the desirability of acquiring as much knowledge as possible while young, and thus laying the foundation to build upon in after-years. Now they have only a vague idea of what they will require hereafter, and they will find in course of time that knowing the names of plants and how to describe them in a scientific way will not be sufficient; they must also become acquainted with kitchen-garden cropping, with fruit trees and shrubberies, and know how to set men to work to the best advantage by day-work, piece-work, or otherwise. Every young man ought to know how to measure and lay out work; to do so, it is not absolutely necessary for him to be able to solve all the problems of geometry, though this is very well for those who are able to do so—but for young men who have not the advantage of a good education, if they can perfectly understand addition, multiplication, subtraction, and division, and can read and write, their own sense, if properly applied, will do the rest. So far as practical gardening is concerned, if they persevere and wait with patience they will some day have an opportunity to use their talents.

To succeed, it is necessary for young men to be humble and obliging, and as they advance in knowledge to show by their behaviour that they do not consider themselves superior to others. If they are clever let them be aware that it is of consideration to others just as they employ their talents usefully. Let them act so, likewise, when they become head-gardeners; by so doing, in place of deserving their master's contempt, they will command admiration, and eventually their masters will reward them according to the service they may render. — KILLWATY ANNOTICES.

NEW BOOK.

Les Plantes à Feuillage Ornemental, par E. ANDRÉ, Jardinier principal à la Ville de Paris. Paris: J. Rothschild, Libraire de la Société Botanique de France, Rue St. André-des-Arts, 13.

The name and position of the author of this volume of 256 pages are a guarantee of the quality of its contents. M. André is no untried contributor to the horticultural periodicals of his own country, and even of ours, for it was only last week that he gave in these columns an interesting account of the public gardens of Paris. In his connection with these it will readily be conceived that he must have acquired a great amount of experience, particularly with the class of plants of which this

volume treats, and which play so important a part in the decoration of the French capital.

M. André, in his first chapter, dwells on the fact that horticulture, like other things, has its fashions, and that a plant, like a pearl or a ribbon, must conform to the universal law. In proof of this he instances the Orange, the Camellia, the Tulip, and the Dahlia, but the Rose, the flower of every age and taste, has alone been an exception. At present plants ornamental by the form and colour of their foliage are the favourites, and such they are likely long to continue, especially as they are capable of producing grand effects in parks and other extensive areas. Of these plants M. André is an enthusiastic admirer, as well as a most successful cultivator, and the information which he supplies respecting them in the succeeding chapters possesses, therefore, a value which it would not otherwise have.

The second chapter treats on the propagation and culture of plants with ornamental foliage, and is divided into sections for annuals, perennials, rock plants, aquatics, climbers, and plants requiring to be wintered in pits, greenhouses, and stoves. Then follows a classification of plants according to their peculiar features and adaptabilities; and in the fourth chapter the subject of planting so as to produce the best effect in gardens and parks, in landscape scenery, and in towns, is entered into at considerable length, and examples are given of different modes of disposing the plants. The fifth and last chapter, of 169 pages, is devoted to a list of fine-foliaged plants, in which the characters, adaptabilities, and culture of each are given more or less fully, according to the importance of the genus in an ornamental point of view. Thus to *Caladium* seven pages are devoted, to *Cannas* twenty-one or twenty-two, and to the important genus *Solanum* about the same number.

The work is written in a clear and pleasant style, is illustrated with thirty-eight engravings, and will be found useful by those desirous of introducing tropical and other ornamental-foliaged plants into their gardens, and cultivating them successfully. It must, however, be remembered, that the cultural directions apply to the climate of Paris. The price, too, is very moderate, being only two francs.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The time has now arrived to commence operations in earnest, and one of the first steps is to plan out every inch of ground for the whole year, if possible. Laths should be written upon and placed at the heads of the quarters, descriptive of the kind of crop, the manuring, and what succeeded by. It is necessary also to keep a cropping-book in order to follow up a systematic rotation corresponding with the labels. Most persons will have laid in their stock of seeds for the year. Seeds remaining from last year should be thoroughly examined, and all that are deemed safe for the current season reserved, and some mixed with the new samples. *Asparagus*, the sooner the beds are manured and soiled the better. A plot of ground should be forthwith appropriated to slopes. Market gardeners avail themselves to a great extent of the immense advantages afforded by sloping surfaces. The slopes should, of course, run east and west, and are most convenient about 3 feet 6 inches wide. They should, if possible, be contiguous to the frame ground, as many of the crops on such banks—as Radish, Horn Carrots, early Lettuces, &c.—will require occasional covering with litter and frequent attention. Slopes of this kind, after carrying their spring and early summer crops, will be equally eligible for autumn ones, more especially for Endive, autumn Carrots, or for raising the stock of winter Lettuces. *Cabbage*, sow a little of an early dwarf kind—the Vanaek or Nonpareil; also a little Round Spinach and a pinch of Early Dutch Turnip on a warm slope. *Cauliflower*, a little to be sown in a box, and placed in a house at work; also Brown Cos Lettuce, and some White Spanish or Portugal Onions to be transplanted to highly manured ground. *Cucumbers*, continue to stir the dung in the fruiting-bed every other day until the plants are ready to be turned out. If it is a dung-bed, before the soil is put in take off the frame, and level the bed if the dung has sunk irregularly. After replacing the frame make a hollow under the centre of each light, and place in it a layer of turf with the grass side downwards; after which put a barrowload of soil, composed of two parts leaf mould, one part loam, and one-fourth white sand, under each light; let it remain a few days, and if the heat in the centre of the drills is moderate, say about 75°, the plants may be turned out. When the frame is

off the lights should be well washed. *Parsley*, sow a little on a warm slope. *Potatoes*, follow up planting at least the early kinds; cover them 8 inches deep, and draw off with the rake or hoe 2 or 3 inches in the first week of April as a cleaning process. *Tomatoes*, sow some seed immediately, that strong plants may be ready to turn out as soon as all danger from frost is over.

FRUIT GARDEN.

When pruning the Plum, Cherry, and other stone fruit trees, it is hazardous to cut off large limbs close to the stem, as gumming is apt to ensue. Shortening-back is therefore advisable in the first instance; and after the sap has had time to find its way into other channels, with the exception of a small portion to keep alive the reduced limb, the latter may be cut closely off with more safety in the following season. Clear off the prunings of Gooseberries and Currants, and dig between the rows. In the case of Gooseberries the surface soil should be carefully drawn back from below the bushes with a hoe and buried in the middle of the space, whence fresh soil should be brought to replace that taken away about the plants. Some persons have strictly followed this plan for twenty years, and have never been troubled with the caterpillar. Make cuttings of choice Gooseberries, Currants, &c., taking care to pick out the buds at the lowest end of the shoot, in order to avoid suckers.

FLOWER GARDEN.

Those who have alterations to accomplish this spring in the way of planting and groundwork, must now lose no time. In planting large shrubs it is an excellent practice to half fill the hole intended for the plant or tree with the rakings of the pleasure grounds. This imparts an unusual degree of luxuriance to the plants, and of a most enduring character too. Look over and correct the general outlines of ornamental plantations. Break into all hedge-like lines, form bold recesses where space will admit of it, and endeavour to create variety. The lines of irregular plantations or shrubberies should be corrected in this way at least every three years, as however well they may have been designed originally, the unequal growth of trees will, in some degree, militate against the first intention. Re-arrange American masses; some of the delicate Azaleas, &c., are frequently overgrown and injured by the grosser *Rhododendrons*. Biennials may be planted in flower-borders or beds. See to the bulbous tribe; stir amongst them, and protect if necessary. As there is no appearance of frost, Moss, Provence, and other hardy Roses, may now be pruned. Cut out as much of the old wood as can be conveniently spared, and shorten back young wood to the most prominent buds. The sooner Roses are planted now the better, except the more tender Chinese kinds. Roll gravel walks, sweep and clean as often as practicable.

GREENHOUSE AND CONSERVATORY.

A great step towards the proper management of stove plants in winter was made when those in flower at this season were found to do well even in a temperature averaging 45° in the conservatory. *Euphorbia jaequiniflora* is one of the best plants we have for winter, and the flowers are even more brilliant in the conservatory than in the stove. Among the forced flowers, *Narcissus*, *Hyaacinths*, early *Tulips*, with some of the different *Roses*, are now the most prominent. Sweet Briar is always welcome in winter, and no place should be without *Mignonette* in pots or boxes. Young Orange trees in small pots may be shifted now and placed in bottom heat in the forcing-pit. No plant delights in bottom heat more than the Orange, and few plants which will live over the winter in a low temperature like the latter. The great point to attend to in the greenhouse, is to keep the plants from growing till as late in spring as possible; such plants as show a disposition to grow early should be removed to the coldest part of the house. *Pelargoniums* and *Cinerarias* require more heat than the woody greenhouse plants, and are kept in houses by themselves in nurseries and large establishments; but where there is only one house for the whole, these may be kept in the warmest end. Cut down, number, and remove decayed *Chrysanthemums*, let them become dry in a cold pit.

STOVE.

Keep the atmosphere rather moist, especially if the weather is bright, and remove to the warmest part of the house such plants as are inclined to start. Above all look out sharply for our common enemies, the scale, mealy bug, and thrips, and wage an incessant war of extermination against them at every point. Some plants, such as *Stephanotis*, *Manettias*, *Allamandas*, *Dipladenias*, &c., may be pruned, trained, and started,

if in a gentle bottom heat all the better, but those plants wanted for late blooming must be kept back for the present. The whole of the *Clerodendrons* to be shaken out of their pots, their roots reduced, and repotted into small pots in light, sandy, loamy compost. Place them in heat until they have made shoots about an inch long, and then, unless required to bloom very early, they may be preserved for a time in a lower temperature. Now is a good time to repot such of the *Orchids* as require it. If you have not yet prepared the necessary materials, do it forthwith. Abundance of peat cut into cubes varying from 1 to 2 inches, fresh sphagnum, and charcoal in lumps, with plenty of crocks, should all be at hand. Commence potting those showing signs of growth, and follow up in this order; half char the peat, and soak the sphagnum in boiling water to destroy insects. Keep *Exoras* close to the glass, and at the cool end of the house, and give abundance of air at every favourable opportunity until the bloom is properly set. Prepare for a general potting next month, and train and clean plants at every opportunity.

PITS AND FRAMES.

Place in heat all kinds of stove plants for cuttings. The various sorts of *Salvia* make beautiful border plants for autumn. The sooner cuttings are struck now the better. They should be potted as soon as they are rooted, and grown in heat during the spring to make strong plants for turning out.—W. KEANE.

DOINGS OF THE LAST WEEK.

THE snowstorm went almost as suddenly as it came, but not without leaving traces of its presence, and of the high winds with which it was attended, on many a beautiful tree and shrub; the heavy weight of snow on the larger branches, increased by the leverage power of the wind, splitting and breaking off many in all directions, notwithstanding the efforts to relieve them of the weight as far as long-handled rakes could reach. Many a symmetrical plant, especially among the *Pinus* and *Arbor Vite* tribe, will have lost their symmetry for years to come. The latter kind of trees are as beautiful to the eye when grown in the regular bush form as when grown to a single stem with the branches coming out regularly all round like a tapering bottle brush; but the superiority of the latter mode of growth is at once apparent in a heavy snowstorm, the snow in their case gliding off the branches without much mischief, whilst in the former many of the contending leaders will be bent to the ground, and cracked and broken. *Cytisus*, *Juniperus*, *Thuopsis*, &c., would all be safer if grown to one stem, instead of approaching the bush form. This fact we may at least learn from the late storm. The disasters among trees and dwellings, &c., on land are after all less to be deplored than the sad news of the loss of life and property from all parts of our coasts. Many a home will be thrown into mourning by the recent hurricane.

As, no doubt, many accounts will appear of the late storm in a gardening and a land-care point of view, it would be interesting to know under what circumstances of general and particular altitude the greatest damage was effected. By the general altitude we would consider the height of the position above the level of the sea, and by particular altitude the height of the place above the neighbouring valleys. Whether it be from the freer course given to the winds on a height, or on the sides of a hill, trees often suffer less on such heights than in the valleys beneath. If this should turn out to be the case in the late storm of wind and snow, it may be partly owing to the well-known fact, that more rain and snow generally fall in the valleys than on the heights, even when the weather is calm; partly owing, we suppose, to the drops increasing in size from their condensing and precipitating upon themselves the moist vapour through which they pass. Even as respects particular altitudes much less rain will fall in a rain gauge fully exposed on the top of a house than one equally exposed some 2 feet above the level of the ground. The height above the ground should be the same when similar rain-gauges are to be compared. Independently of these presumed facts, we have often been mortified, when the ground has been parched-up in summer, to see a rain-cloud break on the hill, and give us only a few drops, whilst the rain was seen falling copiously in the valley. Taking these things into consideration, were we to come to a conclusion beforehand it would be that the greatest damage would be done on low grounds; but facts on this matter will be of more importance than any theory, however

supported by several instances. If the theory should prove to be at all correct, then the importance will be demonstrated of planting chiefly on the poorer land of the hills, and leaving the valley for ploughed fields and meadows.

The frost came and went as suddenly as the snow. On Friday afternoon and evening it promised to be very severe, the glass falling to about 11 below freezing, at 10 p.m., and no change denoted then except a little haziness in the west. Rolling snow for the ice-well was out of the question after the frost, but ice had formed on a large pond, and that being covered with snow, we had holes broken towards evening, and water thrown over the snow by means of a jet, so that the frost should have full power on the pond without the protection of a snow-covering, and we anticipated nice thick ice in the morning, and a day with the ice-cart, though the roads would be rather rough. The ice was thick enough, but on going out in the morning we found the rain, which we could not see, pattering on our face, so sudden had been the change. Having made every arrangement we did not like being thwarted, but after continuing some time the rain and sleet became so fast and furious, and the roads so bad, that we were obliged to desist, and by Sunday morning the snow was all gone. So with us the first chance of obtaining ice for the season has only been partially successful, though even a small quantity is better than none.

The ground being so wet we refrained from going upon it, for digging or otherwise, as much as possible, and the weather being so unsettled the chief work has been washing plants and pots, re-arranging houses, taking most of the bedding plants out of the Peach-house, scraping about half an inch off the surface soil in the orchard-house and taking it to a burning heap—a matter of importance for destroying the eggs of insects if there are any; and in addition to the glass of houses, went over most of the frames and pits, washing the glass inside and outside, putting on some spare sashes, so as not to expose the rather tender inmates long, and doing this near sheds, so that if a heavy shower came on, the men might be employed in washing pots and mending and making straw covers for protection. These are in every way superior to mats, but not equal to wooden frames or shutters. In the press of work some sashes of frames were left uncleaned in the autumn, and without seeing it we could scarcely have believed how dirty and slimy the glass would have become from the want of the autumn washing. No doubt this sliminess was greatly increased by the damp sunless weather we have passed through.

KITCHEN GARDEN.

The work here has been chiefly confined to sowing Peas and Beans in half-circle drain-tiles and on pieces of turf for future transplanting under protection. Removed Kidney Beans from Vine-pits where they were about done, as we wanted the room for moving and regulating the Vine-shoots. Placed Potatoes in pots near the light, in a pit where there was a little heat from leaves. Swept over the last spawned Mushroom-bed so as to have the surface clean and smooth. Looked after large snails at night, as they had begun to have more than their share; they generally make their appearance now about nine or ten o'clock in the evening, and go back to their holes long before daylight. They are generally brought in with the tree leaves, &c., which we use for the bottom of beds. Put a little more Rhubarb in the Mushroom-house. Cut the Sea-kale before it grew too long, as it came faster than we wanted it, and put it in a cool place, on damp moss in a pot, with another pot over it, for a few days. We are sorry to find that some good Cauliflowers in an earth-pit have damped from being covered up several days. Nothing else has suffered, though the covering remained on until Monday. Washed the glass over Asparagus to give it all the light possible, and put on sashes with good glass and large squares, instead of the inferior ones which we were obliged to use at first. Have very little of a fermenting-heap, but intend to raise a bed that has been used for other purposes, in order to sow Horn and Early Dutch Carrots in rows 6 or 7 inches apart, with Radishes in rows between, drawing out the Radishes early, and thinning the Carrots chiefly by drawing. Such a bed of Carrots not much thinned is one of the most profitable things in the garden. We have sown a lot of Newington Wonder Kidney Beans, having run out of other sorts, but though this kind is small it is prolific and well-flavoured, and when the pods are not more than 1½ or 2 inches in length, they are very good cooked whole. We often think that even in the case of larger pods, though quite fresh and young, the flavour is often rendered very flat and watery from the pods being minced and cut into such small pieces before boiling. All

Kidney Bean pods are too old for cooking when they do not break at once, and crisply, when you attempt to bring the two ends of the Beans together. Other matters much the same as in previous weeks. In case frost should come, though there is at present no appearance of it, took up the remainder of the Parsnips, and a lot of Horseradish and Jerusalem Artichokes, secured the Globe Artichokes with litter, and placed burnt clay and burnt rubbish over the crowns of Sea-kale.

FRUIT GARDEN.

Cleared most things out of the Vine-pit, so as to be able to regulate the shoots. Examined and cleaned Strawberry pots in this pit, and filled two shelves in the Peach-house with Strawberry plants, setting the pots on turf reversed on the shelf that overhangs the pathway, and in saucers where the shelf overhangs the trees and can be easily examined. These pots were just gently excited from standing close to the glass in a frame, where there was a little heat below them from leaves, placed above what had been a Melon-bed. Nothing is better than such a frame for giving the plants a quiet start, and nothing, scarcely, can be worse at this season than giving such plants as much heat as would encourage them to root freely in the leaves. If these have to be moved to shelves the check given is often fatal to success, and the whole process tends to the encouragement of leaves rather than flower-stems. If the heat is more than the mildest the pots would more safely be placed on boards and tiles, instead of being plunged in the bed. Allow us to remind those who have their Strawberry plants in frames or under glass, to keep a sharp look-out after mice and rats, and especially the former, as a few of our plants with nice crowns, and the trusses showing well, have been nibbled and cut by mice until they are useless. What with one enemy or another it is seldom that a gardener can have unbroken ease and satisfaction even for a day. There is always some interloper that does the best to mar his best-laid plans, and at least to keep him ever on the alert. If the present dripping weather continues, we will have the orchard-house and trees thoroughly washed. We gave them a good smoking with bruised Laurel leaves when the roof was covered with snow, and the house still retains the scent of the burning smothered leaves. There could have been no better time for smoking greenhouses, conservatories, and frames, where such a smoking with tobacco was necessary. A cool, airy atmosphere is the great preventive of insects. We have not yet needed any smoking with large plants of Cinerarias. For other matters, as respects fruit and fruit trees, see previous weeks.

ORNAMENTAL DEPARTMENT.

Chose a dry time, as soon after Monday as was practicable, to sweep and level some walks that had been rendered rough by shovelling and sweeping pathways in the snow. A small snow-plough—say formed chiefly of three boards, making a triangle, the sides being 4½ feet long, and the base 3½ or 4 feet, the boards 2 inches thick, and 11 or 12 inches deep, is the best means for making walks passable when covered with snow, as it will leave a covering of snow over the gravel, though thin, and thus prevent the smooth surface of the gravel being interfered with. These three pieces of the triangle, braced by stout pieces between, and a weight placed on these in proportion to the depth of the snow, a string or chain fastened to the acute angle in front, and a handle behind to hold by and push, will enable two or more men, according to the depth of the snow, to secure walking-space in a short time over a great extent of walks. One good result of the snow is, that it has filled all pools, ponds, and other receptacles for water to a greater depth than they have been for many years. The ground has also had a soaking, such as it has not had for many years in this neighbourhood. The mild weather has encouraged the worms to throw up their heaps on the lawn, and to keep them out of sight the lawn was run over with a light wooden roller, a smooth green lawn being now a great attraction. A nice lot of Pinks in pots, we are sorry to say, have been nibbled by the mice, as if for mere mischief. Even tarring a rat has not made them all decamp. Wherever much grain is thrown down for game near gardens there is sure to be more than enough of mice, rats, and birds. At present, even as respects birds, every compact Laurel bush seems to give a roosting-place to hundreds every night.

In the case of Auriculas, Polyanthus, and Carnations, the great point is to keep them from becoming too damp, and yet give plenty of air by raising the front and back of the lights, but keeping the damp out. Drip from the sash-bars must be avoided in the case of valued plants of Auriculas.

In dry hours the driest soil should be housed and well aired for potting and other purposes. The snow acted as a good protection from the frost of Friday night, as everything exposed and in cold pits was more tender than usual, owing to the mild sunless weather. Our Calceolarias, &c., were covered up from Wednesday to Monday, and were all right, as a little extra damp would not hurt them. We are having the glass washed, which will make the plants more stubby. Most of them are resting now, and it is quite time enough, for if they grow fast they will be too thick before we shall be able to thin them by planting them in an earth pit without glass protection. Gave plenty of air, without rain, to Violets. Will soon begin to pot some Searlet Geraniums that are very close together in boxes. Cleared any dead or damped parts from the tops of those that were taken up from the beds and put in large pots as if they were so many faggots. Most of them are beginning to break nicely, owing to the mildness of the weather. If they had done so a month or six weeks later, they would have been early enough. Fresh arranged plant-houses, and will have a lot of potting done if this dripping weather continue. All the houses are kept at about the temperatures mentioned lately.

HINTS TO BEGINNERS AND WINDOW GARDENERS.

There are a few matters to which, in addition to what was said lately as respects bulbs and forced plants, we would respectfully direct the attention of beginners and window gardeners.

1st, Endeavour to have all glass and woodwork clean. Clean water with the chill taken off is often the best, as if much soap is used the alkali is apt to make havoc with the paint. A little brown soap will do no harm.

2nd, Let all pots be scrubbed clean with a brush, and a little sand, if very dirty. It is safest to use nothing but clean soft water for this scrubbing. Never on any account put a bulb or a plant into an old pot that has not been well washed inside and outside, and then allowed to dry before using it. Even rubbing the inside of the pot with a dry scrub is a poor substitute for washing. If many pots are very dirty, they may be soaked some hours before washing, the water poured off, and warm water, to be comfortable, used, and, on the whole, simple water is the best. A little soda or potash may be added, if the pots are very dirty, but in the case of soft pots such ingredients cling to them a long time.

3rd, Keep all leaves and stems of plants, and especially in windows, free of dust, and if it settle on them, brush and then wash it off. A bath will be of importance to the tops of window plants, as it will help to neutralise the dry atmosphere of a sitting-room. There is no better plan for washing the heads of plants of moderate size, than having two pails or tubs filled with clean water at a temperature of from 60° to 70°. If the plants are very dusty, brush the foliage with a soft brush when dry, then place a cloth on the top of the pot, and with the fingers of the left hand spread over and holding the pot, reverse the head of the plant in the water, pulling it backwards and forwards several times, and then set the pot on the floor with the head in the usual position, and wash leaves and stem with a soft sponge until you learn to use the fingers and thumbs of both hands, which may be applied softly and quickly to both sides of the leaf. Then swinge the head again through the same pail, and if that leave it pretty clean, pass it once more through the clean water-pail, and the appearance of the plant will be more than a reward. The cloth and fingers over the surface of the pot will prevent the earth falling out, and the cloth will prevent the earth being soaked in the cleansing operation.

4th, Pay great attention to having the soil rather dry, warm, and well-aired before using it for potting. Those who want so much as to have a small stack of this pared turf, and thatched with itself by turning the grass side outwards, will only have a minimum of care in having the soil aired, as if such turf is built in a narrow ridge and somewhat open, the air will enter sufficiently to sweeten it in six months or so, without turning or anything of that sort. There is scarcely the side of a highway where nice soil suitable for all common plants may not be had.

Lastly, in watering in winter and spring, the water should only be given as wanted, and if the fires in a room are pretty strong and the sun bright, a sprinkling over the top will often be better than saturating and deluging at the roots. When a sunny day comes after a week or a fortnight of dull weather the shade of a muslin curtain for a few hours will often be better than watering. When, however, the soil is dry, watering for a

potful of roots should be given so as to moisten all these roots. The water should be soft, and as warm or a few degrees warmer than the atmosphere of the house or room. For particular plants it is best that the water should be warmed, without taking hot water out of a metal boiler to mix with cold water, as in some such cases there is too much of an oxide or other salt of iron in the water. We have known Ferns &c., injured by watering with water taken from the cistern of hot-water pipes in a forcing-house. We are often glad, however, to go to such places in winter and spring when warmed water must be had. A great advantage, even in large gardens, would be either a large copper for heating water alone, and boiling manure water, and then cooling it before using it, or a large cistern with a coil of hot-water pipes at the bottom, so that the water would be heated without being affected by the rust of the iron inside the pipes. For window plants a tin pitcher or an earthenware vessel might be set by the fireplace. For most common plants a little hot water from the kitchen boiler, to mix with the soft water, though cold, will answer well enough; but it is right that the cultivator of a single plant should know the best mode of securing water that has had the chill taken from it.—R. F.

TRADE CATALOGUES RECEIVED.

Barr & Sugden, 12, King Street, Covent Garden, London.—*Descriptive List of Choice Seeds for Flower and Kitchen Gardens.*

W. Cutbush & Son, Highgate, London, N.—*Catalogue of Vegetable, Flower, and Farm Seeds.*

Hooper & Co., Central Avenue, Covent Garden, London.—*General Spring Catalogue.*

R. Parker, Exotic Nursery, Tooting, Surrey.—*Catalogue of Agricultural, Flower, and Vegetable Seeds, Fruit Trees, New and Rare Plants, &c.*

William Paul, Paul's Nurseries and Seed Warehouse, Waltham Cross, London, N.—*Select List of Vegetable, Flower, and Agricultural Seeds, Seed Potatoes, &c.—Price List of Paterson's Seedling Potatoes.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Seeds for the Kitchen Garden, the Flower Garden, and the Farm.*

COVENT GARDEN MARKET—JANUARY 20.

Good dessert Apples and Pears find plenty of buyers; but the supply is limited. Pines are sufficient for the demand, as also are Grapes; some good Black Hamburgs are still to be had, but the bulk consists of Barb arossa, which commands nearly the same price. Forced Strawberries have not yet made their appearance. Among foreign imports are Green Peas from Spain and Algeria; consignments from France chiefly consist of Salads, Artichokes, and Asparagus, the latter selling at from 25s. to 35s. per bundle. Greens of all kinds are very abundant and cheap. Good samples of Potatoes are saleable at a trifling advance on former quotations.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

RIBBON BORDER. *P. G.* Your proposed arrangement will look very well. Let us know what four Geraniums your propose for a ribbon-border, and we will give you our opinion.

HEATINGS. A SMALL BOILER BY GAS. *R. S.*—For seven postage stamps you can have free by post from our office "Greenhouses for the Many." At page 38 there are a plan and descriptions that will guide you well.

IN DOOR SPIDER ON PEACH AND NECTARINE TREES. *Insurance, horticulture.* If your trees are infested with small flies, and paint the wall with a wash of sulphur vivum, 2 lbs.; soft soap, 8 ozs., dissolved in a gallon of water; soft, 1 lb.; fresh lime, 1 lb.; clay, 1 lb. Mix the sulphur, lime, and soft with a little of the soap solution, then add the clay and enough of the soap solution to make the whole like paint. Brush the mixture into all the crevices, in fact, fill the soap. To free the trees are nailed to the wall wash them with sulphur vivum, brought to the consistency of paint by a solution of 4 ozs. of soft soap in a gallon of water. Apply with a brush, taking care not to injure the buds. If red spider attack the trees in summer syringe them with water frequently, and now and then with 2 ozs. of soft soap dissolved in a gallon of water.

BOOKS. *Henry Clarke.* "The best book on wild flowers" demands upon the purpose for which it is required. For identifying species Hooker and Arnott's "British Flora" is as useful as any according to the Natural System; Sir J. E. Smith's "English Flora" according to the Linnaean. We cannot state the prices. Heliborus fatidicus might have its flowers improved by crossing with the *Christinus* form, but we have never heard of the experiment being tried. *D. H. J.* "In-door Gardening" will probably suit you, price 1s. 6d., free by post from our office for twenty postage stamps. *(L. M. T.)* Three very small books, 1s. 6d. each, will completely supply your requirements. "The Garden Manual," "Out-door Gardening," and "In-door Gardening." For six extra postage stamps they may be had free by post from our office.

EXHIBITING AT THE INTERNATIONAL HORTICULTURAL EXHIBITION. *(A Practical Gardener in the North.)*—Regulation 11 says, "Every exhibitor must be prepared to declare that the objects he exhibits are his own property, or that of his employer," which we consider intends that a gardener, or an amateur, must not exhibit anything purchased. If a gentleman has a residence in the south of England and a residence in the north, we think the products from the gardens of those residences might be exhibited in one collection. Cucumbers we consider come within the comprehensive name "Salading." An intending exhibitor accidentally prevented exhibiting, after giving notice of his intention, does not incur any responsibility by his non-exhibiting. Potatoes, Peas, Dwarf Kidney Beans, Mushrooms, Tomatoes, and Carrots, would form a good collection. Of course excellence in each article will be a paramount consideration.

LEWISIA BIRDVIA. *(D. V. and many others.)*—We do not know any one who has this plant. It is probably at Kew, but so numerous are the inquiries for it that any nurseryman obtaining it and raising a stock would profit well by the effort.

VINES FROM EYES. *(Cherise D'Amiens.)*—The eyes from shoots of the preceding year are always used, of course from shoots that are properly matured. In the "Vine Manual," which you refer to, it is expressly directed (page 26) to take the eyes from shoots found and of medium robustness.

HOUSE SEWAGE. *(Thos. L. Carter.)*—The chamber slops diluted with five times their quantity of water may be applied about twice a week to your Rose trees, &c., so soon as growth commences in the spring. It is so rare that useless to apply manure to any plant whilst it is dormant in winter.

PRIMULA. *(P.)*—The variety of *Primula* you sent is not new. Many similar varieties were exhibited last year. Brightness and distinctness of colour are more to be desired than these pale varieties.

COVENT GARDEN MARKET MEASURES. *(E. C. E.)*—It is not available to quarrel with the Covent Garden Market dealers about the measures they employ; but to help you and other country readers we will add a definition of some of those measures. *Bottle:* A long, tapering basket, made of deal shavings, holding about a pint and a half. *Scotch Punnet:* 8 inches diameter at the top, and 7½ at the bottom, and 2 inches deep. *English Punnet:* 8 inches diameter and 1 inch deep, if to hold six hands; or 9 inches by 1 inch for twelve hands. *Mushroom Punnet:* 7 inches by 1 inch. *Salading Punnet:* 5 inches by 2 inches. *Half Sieve* contains three imperial gallons and a half. It averages 12½ inches diameter, and 6 inches in depth. *Sieve* contains seven imperial gallons. Diameter, 15 inches; depth, 8 inches. *Bushel Sieve*, ten imperial gallons and a half. Diameter at top, 17½ inches; at bottom, 17 inches; depth, 11 inches. *Bushel Basket* ought, when heaped, to contain an imperial bushel. Diameter at bottom, 10 inches; at top, 14 inches; depth, 17 inches. Walnuts, Nuts, Apples, and Potatoes are sold by this measure. A bushel of the last-named, cleaned, weighs 56 lbs.; but 4 lbs. additional are allowed if they are not washed. The hand of *Rushes* varies with the season.

CINERARIAS WITHOUT PETALS. *(G. G. E.)*—We are unable to account for the absence of petals, but we think that it proceeds from the plants being too cross, from their being kept too far from the glass, and too close and warm. Give them a light airy situation and a temperature not exceeding 45° from fire heat, and we think that if the blooms proceed afterwards there will not be many without petals. It is not unusual for the first blooms of early plants to be without the corolla, but it is not so throughout, the fringes having that tendency only at the commencement of flowering. The Beans you sent are—1, Common Dwarf Kidney Bean; 2, Red-speckled Kidney Bean.

SPRINKLING EARLY CROCUS BLOOMS. *(Thompson's Subscriber.)*—Put in stakes or sticks at every 6 feet or so, and stretch black thread or worsted from 9 inches to a foot above the Crocuses, fastening at every 3 feet along the threads a small piece of glass. The birds will alight, but when they see the thread and pieces of shining glass hanging above their heads they will go off directly.

BORDER FOR HERBACEOUS PLANTS AND ANNUALS. *(G. H.)*—Your border of sandy yellow loam would be improved by trenching 18 inches or 2 feet deep, and that is all we should recommend to be done at present. Yellow loams are mostly fertile, and well suited for the growth of herbaceous plants, the sandy nature of your's rendering it all the better, as the plants will not be so liable to go off in winter as if the soil were of a heavy wet nature. Hardy herbaceous plants: *Astragalus officinalis*; *Agrostemma corymbosa*, and var. *purpurea*; *Aquilegia scrophularioides*; *A. glandulosa*, and *A. fragrans*; *Aster tuncacetifolius*; *Betonica grandiflora*; *Campylobasis nigra*; and *C. speciosa*; *Cheiranthus Marsballii*; *Dicentra spectabilis*; *D. spectabilis alba*; *Dodecatheon meadia*, and var. *elegantis*; *Fritillaria imperialis* vars.; *Geranium sanguineum*, and *G. lanceolatum*; *Gemma coccinea grandiflora*; *Hypericum calycinum* (St. John's Wort); *Iris germanica* vars., *I. pallida*, *I. xiphoides*; *Lilium tenuifolium*; *Lobelia urens*, *L. fulgens*, *Sr. Clair*; *Lycalis Haageana*, and its variety *superba*; *Lythrum roseum superbum*; *Paeonia alba*, *P. arctica*, and *P. officinalis* in variety; *Papaver nudicaule*; *Phlox canadensis* and varieties; *Polemonium cornutum*, and variety *variegatum*; *Potentilla alpestris*, *P. splendens*, *P. Menziesii*, *P. MacNabiana*, and *P. bicolor grandiflora*; *Pyrethrum carnum*, and many double vars.; *Salvia pratensis*; *Scabiosa grandiflora*; *Spirea filipendula plena*; and to these may be added *Carnations* and *Pirotees*. The preceding grow to a height of from 1½ to 2½ feet, and are well suited for third and fourth rows. The following, growing from 6 inches to 1 foot, and occasionally 18 inches high, are well suited for first and second, and also third rows when the border is wide:—*Achillea aurea*, *A. chvrenca*, *A. nana*; *Ajuga alpina*, *A. alpina rosea*; *Achemilla alpina conjuncta*; *Allium fragrans*; *Alyssum saxatile compactum*; *Anemone nemorosa plena*, *A. pennina*, *A. palmata*, *A. japonica* *Honorine Jobert* (1½ feet); *Antennaria hyperborea*; *Anomatheca cruenta*; *Antirrhinum* in variety (1½ feet); *Aquilegia alpina*; *Arabis alba*, *A. bellidifolia*, *A. hieda variegata*; *Aubrietia deltoidea grandiflora*; *Aster alpinus*; *Asclepias tuberosa*; *Bellis perennis acumbifolia*; *Calandrinia umbellata*; *Campylobasis muralis*, *C. gargarica*, *C. pulla*, *C. pusilla*, *C. fragilis*; *Cerastium tomentosum*; *Colchicum autumnale flore pleno*; *Conwallaria majalis*, and gold-striped, pink, and double-flowered vars.; *Crocus sativus*, *C. autumnalis*; *Dianthus deltoideus*, *D. barbatus*, *D. Heddeburghii*, *Dianthus Highclere vars.*; *Draba aizoides*; *Dryas Drummondii*; *Eranthis hyemalis*; *Erigeron grandiflorus*, *E. speciosus*; *Galanthus nivalis*, *G. plicatus*; *Geumina verna*, *G. aculeis*; *Heutopia triloba* in variety; *Iris sibirica*, *I. reticulata*; *Leneojum verum*; *Lotus corniculatus flore pleno*; *Muscicla lyvatioides*; *Myosotis sylvatica*; *Narcissus Ajax*, *N. conspicuus*, *N. juncifolius*; *Etiolonia macrocarpa*, *E. variegata*; *Orchis verna*; *Ornithogalum nutans*; *Oxalis tropaeoides*; *Primula acaulis* in variety; *P. hortensis*, *P. auricula* in variety; *Pulsinaria officinalis*, *P. angustifolia*, *Hannuculus amplicaulis*; *Saponaria oymoides*; *Scilla amena*, *S. sibirica*, *S. hollia*, *S. verna*; *Silene alpestris*, *S. Schafar*; *Stachys lanata*; *Stemodia lutea*; *Statice Gmelini*, *S. latricia*; *Tigridia pavonia*; *Trichocoma bulbocodium*; *Trollius europaeus*, *T. albus*, *Tussilago farfara variegata*; *Veronica alpestris*, *V. caudata*; *Viola odorata* vars., *V. cornuta*, *V. pennsylvanica*, *V. snayley*, and *Zephyranthes candida*; to which may be added *Pinks*, *Sweet Williams*, and *Double Rocket*. Taller plants for the back rows: *Campanula pyramidalis*; *Polystachyum vulgare*; *Delphinium Belladonna*, *D. formosum*, *D. Hoopsii*, and *D. bicolor grandiflorum*; *Lilium candidum*, *L. lineifolium*, *L. Brownii*, *L. aurantiacum*, *L. chalcidicum*, *L. martagon*, *L. tigrinum*; *Lupinus arboreus*, *L. polyphyllus*; *Papaver bracteatum*, *P. orientale splendens*; *Tritoma naria*, to which add *Hollyhocks*. We have proved these and found them good. We could name more, but as you only require select kinds we go no further. If too many are named take a part. To have annuals in the intervals you must allow a space between the plants or rows equal to the height the plants attain, in addition to that required for the herbaceous plants. A dressing of any artificial manure scattered over the border between the plants in April, and going over the ground with a hoe, will do them good, and it may be repeated in six weeks. A dressing of leaf mould early in winter will be as beneficial as a dressing of rich manure. It should be put round the plants 3 inches deep at the back, and an inch in front, allowed to remain all the winter, and be pointed-in in March.

TUBEROSES AND GLOXINIAS AFTER BLOOMING. *(A Subscriber, H. C.)*—After blooming gradually withhold water, giving only a little to prevent the leaves flagging, and keep the plants in a light airy situation until the foliage be decayed; then place the pots containing the tuberoses in a dry part of the greenhouse, and give no water. In March remove the plants, removing all the old soil unless they have roots, when only so much of the old soil should be removed as can be done without injuring these. A compost of turfy loam, rich loam, and one-third leaf-mould, answers well, adding sand if necessary. Grow the plants in a light airy part of the greenhouse, and as near the glass as possible, syringing frequently to keep down red spider, which is their great enemy. After the foliage of the Gloxinias has decayed the pots are to be placed on a damp floor, which will keep the soil a little moist, though it will appear dry. This will prevent the tubers from becoming farinaceous, as they are apt to do when kept on a shelf with soil dust-dry, and consequently rotting when the soil is moistened in spring. To winter Gloxinias safely the temperature should seldom be lower than 45°. In February or March they should be potted, removing all the old soil; and if the soil is in nice order and just moist they should not be watered, but be placed after repotting in a mild hotbed of about 75°, and there remain without water until they begin to grow, when water should be given cautiously at first, increasing the quantity as the plants advance in growth. They should be retained in the hotbed until far advanced for blooming, when they may be removed to the warmest part of the greenhouse, where they will do well after the middle of May. Without heat at the recommencement of growth Gloxinias cannot be grown satisfactorily in a greenhouse. If you start them in February they will bloom in June, and in July if started about the end of March or beginning of April.

ASPARAGUS FOR COVENT GARDEN MARKET. *(Working Gardener.)*—It is quite useless to expect the prices you mention (except for bundles of uniformly fine heads). You had better write to Messrs. Webber & Co., Covent Garden Market, and state what you purpose doing, and ask if they would take your produce.

POLYANTHUS FROM SEED. *(James N.)*—To succeed in raising first-rate Polyanthum seedlings, you must obtain the best kinds of plants and sow your own seed. You can buy plenty of seed in the market, but you cannot expect to purchase what has cost the grower much thought and care in hybridising, &c.

WEATHER WISDOM (*John Bryon*).—Weather charts, price 2s. 6d. (by J. Glaisher, Esq., F.R.S.) as used by the Royal National Lifeboat Institution, can be purchased at Negretti & Zambra's, 155, Fleet Street, London, E.C., and such charts will last a year, or longer if the observer do not mind tracing the barometric line for two or three months on the same chart, using each time different coloured lines. Full explanations of the way to use a chart, with charts for use in the book itself, are to be found in a small work (price 1s.) entitled "How to use the Barometer," published by Debenroes & Sons, 21, Paternoster Row. This is a very useful book for observers of weather who wish to learn how to record the fluctuations of the barometer, of wet and dry bulb thermometers, and the direction of the wind. The best kind of barometer for gardening purposes is the Farmer's Barometer by Negretti & Zambra, price 2s. 10s., and attached to this instrument is a dry and wet bulb thermometer. There is a small and cheap portable barometer (price 12s. 6d., by Casella, 23, Hatton Garden, London) called the Agricultural Barometer. Mr. Casella warrants it to work very accurately for general purposes. One such instrument has now been in use for more than twelve months, has travelled from near London to Scarborough, and further northward, and back again without injury, and reads pretty accurately with a Standard Barometer. Once, indeed, the readings taken by Casella's instrument were sent by "X." on a chart to Mr. Glaisher. The chart was corrected by the readings taken at the Greenwich Observatory, and those readings were not very different (for general purposes) from those observed by the 12s. 6d. barometer. The tube of the barometer is very small, but this weather glass is a cheap one, and is not to be despised. A dry and wet bulb thermometer, sufficient for weather purposes, can be purchased of Negretti & Zambra for 12s. 6d. Standard instruments, for scientific purposes, are very expensive, but they are not really required for a gardener's use. When "X." in his remarks, page 525, said "There is no expense attending such observations," he meant that there was no expense incurred in noting down the weather (in a chart for a year costing only 2s. 6d. or less), after the first outlay had been made by a master in providing suitable instruments for his gardener.

HARDINESS OF CERTAIN FERNS (*H. G. S.*).—Of the Ferns named *Lastrea delicatula* requires a greenhouse, but not a cool one; *Asplenium Belangeri* will do in a greenhouse, but needs a stove to do well; *Campyloneuron phymatodes* (*Pleopeltis phymatodes*, also *Drynaria vulgaris*, and *Asplenium foveolatum* are stove Ferns. *Lastrea Standishii*, has not, so far as we know, been proved to be hardy, but it is likely to be so. This fine new Fern certainly does well in a cool house or frame. *Lastrea patens* is of continental origin, and, as we had it, did not succeed at all well in a greenhouse fernery, but it grew luxuriantly in the stove. *Davallia canariensis*, *Nephrodium molle*, and *Pteris longifolia* require a greenhouse; and *Asplenium* (*Cyrtomitium*) *falcatum* is only hardy in warm sheltered situations, doing much better in a cool house than anywhere out of doors.

APPLE TREES INFESTED WITH INSECTS (*D. Barton*).—The trees should have a dressing of 8 ozs. of soft soap dissolved in a gallon of water along with 8 ozs. of salt. Apply it at a temperature of 100°, brushing it well into the crevices. This will free the trees of insects and moss, and should be applied now. Be careful not to injure the fruit-buds by rubbing. No specimen came in your letter.

CAMELLIA-BUDS AND LEAVES FALLING (*Idem*).—From the plants losing their leaves and being in a bad state of health, we should think that there is something the matter at the roots. Is the drainage good, and the soil sweet and not soddened with water? If not, then it should be. Are the plants watered when they require it, and only then? The soil should always be kept moist, at the same time no water should be given until it is required. An imperfect root-action is the most likely cause of the buds falling.

FERNS WEAK—PRIMULAS DAMPING OFF (*Idem*).—Your Ferns are weak from being kept too warm. They will become strong if properly potted, well supplied with water both at the root and in the atmosphere, and kept in a proper temperature, with good ventilation. The Primulas damp off from being constantly watered. They would not be so liable to damp-off if the surface of the soil in the pots were covered quite up to the collar of the plants with small pieces of stone. These should range from the size of a pea up to that of a hazel nut. From one-half to three-quarters of an inch is sufficient. Give more air, and do not water so often; give plenty of water, but only when they require it.

TIME OF FORCING STRAWBERRIES (*Idem*).—The beginning of February is a good time, and early enough to have a good crop. They cannot be forced with a prospect of a full crop before that time, and the longer it is deferred the more plentiful the fruit will be. Thompson's "Gardener's Assistant" contains the necessary information for the pruning of fruit trees.

RHUBARB RUNNING TO SEED (*A Moonraker*).—It throws up flower-stems more abundantly when planted in poor than in rich ground; but it will produce its large umbels under any circumstances after it has been planted three or four years, some kinds more than others. This weakens the roots very much and should not be allowed. Cut away the seed-stems, when you first perceive them, level with the ground, and this will induce the formation of crowns at their base, instead of the energies of the roots being expended in the production of seed. It would be well to take up the roots now, preserving as much soil attached to them as possible, and after trenching the ground, and working in a liberal amount of manure, to replant, dividing the roots if large; but they will not produce so well the first year as if they had not been divided. If you cannot take the Rhubarb up and prepare the ground properly, give a good top dressing of manure, and point it in, not going so deep as to injure the roots. A good watering of liquid manure now and then in summer will make it stronger.

RHUBARB FORCING (*Idem*).—If your dark cellar is sufficiently warm it will answer admirably for forcing Rhubarb. The temperature should not be less than 50°. It is not too late, for if you put roots there now they will produce long before stools in the open air unheated and uncovered. You may pot the roots in Vine pots as you propose, or spread a little soil on the floor, place the roots on it, and then cover them with moist soil. There is this advantage in forcing Rhubarb where it grows, the roots are but little injured and may be forced every other year without any great deterioration, whereas if they are taken up and placed in a cellar or elsewhere they are of little value afterwards, requiring more time to recover than is needed to raise from offsets roots of greater strength, and in every way better for forcing-purposes.

CUCUMBERS AND MELONS IN PIT HEATED BY HOT WATER (*R. J. Wheeler*).—Your pit would do well for the growth of Cucumbers and Melons, provided you could form a bed over the tank, and leave the sides of the tank exposed so as to heat the atmosphere; but as you will not be able to do this, from the top of the tank being level with the bottom of the pit, we would advise you to place 6 inches of rubble over the bottom of the pit as well as upon the tank, and above the rubble a layer of sods, grass side downwards. Over the tank insert a drain-pipe or tile, with a bore 3 inches in diameter, at every 2 feet, the lower end going through the sods into the rubble, and the other opening into the pit. These pipes should be inserted perpendicularly, and through them heat will ascend and give a sufficient atmospheric temperature, and the heat from the tank going amongst the rubble will give bottom heat. Three inches of soil all over the sods will be sufficient to begin with, but immediately under the centre of each right place about half a barrowful of soil in the form of a cone with the top flattened, and exactly 1 foot from the glass, so that you must make the rubble so thick that you will have 10 or 12 inches of soil over it, and yet have the tops of the cones of soil 1 foot from the glass. When the soil of the cones has become warmed through, plant in the centre of each two Melon or Cucumber plants, one to be trained to the back and the other to the front of the pit. If you have the plants to prepare, sow the seeds in pots, plunge these in the soil, pot off, and finally plant in the centre of the cones. When the plants grow, the space between the cones and the sides of the pit is to be covered or filled with soil by degrees, placing it against the cones so as to cover the bed with soil nearly level with the tops of the cones. The tops of the tiles will be a little above the level of the soil, and must be kept free. You may raise from seed any plants you like in the pit, at least such as require heat, so long as they do not interfere with the Cucumbers and Melons. Remove the plants before they do that. Your other frames will answer for hardening off the plants raised in the heated pit. Cucumbers and Melons do not succeed well in the same compartment, you should, therefore, have a division or rather partition wall.

PRUNING RECENTLY-TRANSPLANTED LAURUSTINUS (*A Subscriber, Allerton*).—It is not safe to cut in these shrubs in winter, for that is their blooming season. They are not the hardiest of shrubs; hence, when they are cut in in winter they frequently die down. Let them alone until the first week in April, and then cut them in to the desired shape and dimensions. The heads will assist the shrubs to form roots, and they will further protect the shoots of which these shrubs are seldom devoid at the base.

GARDENER ILL-TREATED (*One in Trouble*).—We have a letter for this correspondent if he will send us his address.

VINES IN POTS (*J. Naylor*).—Your Vines in pots, one year old, with canes 5 feet long, are, we presume, too weak to fruit. If not strong—that is, if much less in diameter than the little finger, and the eyes are not large and plump, cut-in to two eyes now, and replot in the same pots after shaking away most of the old soil. If the Vines are strong, the eyes plump, and the wood brown and hard, do not prune them at all, but pot them at once in 15-inch pots, providing good drainage, and using a compost of rather light, rich, turfy loam. Those in 14-inch pots may be fruited in that size, and in that case you will merely have to look to the drainage and remove the surface soil and replace it with rich compost. If not already done they should be pruned at once, cutting them in to 6 feet. You may not do this in 18-inch pots, but do not disturb the ball, though you may slightly loosen the roots around it. Vines in pots require the same temperature as Vines in borders, and this you will learn from the "Vine Manual" which you have; but we may state that for the first fortnight the temperature from fire heat should be from 40° to 45°, for the second fortnight from 45° to 50°, for the third fortnight from 50° to 55°, and in a week it should be increased to 60°, and at that it is to be maintained until the flowering takes place. That and the setting over, we increase the temperature to 65°, and continue that heat until the fruit changes colour, when we lower it 5° by night from giving more air, and this is continued until the fruit is ripe, when we lower the temperature as much as practicable, but not below 50°. On these temperatures we allow a rise of 5° on dull days, 10° on those which are cloudy with clear intervals, and from 15° to 20° on bright days. Elphinstone published a little book on Vines in pots, but it is now out of print. The subject will be treated of shortly.

LEAVES OF MRS. POLLOCK GERANIUM ALTERING (*E. G. H.*).—The leaves lose the markings from the plants being kept in too close and warm an atmosphere. The stove only forces them into growth. Geraniums of the tricolor-leaved section are less faint in their markings in a stove in winter than in a greenhouse; but the marking is much less bright in winter anywhere than in spring and summer. Geraniums do not require steaming and roasting in stoves. Most of the nurserymen who advertise in our columns can supply you with Geraniums.

GARDEN INFESTED WITH SLUGS (*W. E.*).—You must not apply gas lime now and crop with Potatoes. The gas lime should be put on in autumn; one-third of the quantity is sufficient, a hundred bushels per acre being a good dressing of fresh lime. If your garden have fruit trees in it do not use gas lime, but fresh lime, and it will kill slugs. March is a good time to apply it. Slake the latter so as to reduce it to powder, then spread it over the ground when the weather is mild, and turn it in. If you give your ground a dusting of fresh lime on the evenings of mild showery weather at intervals in summer, your garden will soon be free of slugs. Be cautious in using gas lime; it will kill vegetable as well as animal life, and is not safe to use in a garden, nor anywhere until it has been exposed to the action of air and water for a considerable time.

PELAGONION LEAVES MILDEWED (*S. B.*).—The tips of the leaves are badly mildewed. Dust them with flowers of sulphur. They have the appearance of having been injured by frost. Give the plants all the air possible, and keep the leaves dry; keep the plants near the glass and as cool as possible, but exclude frost. Give air early, and always when the external atmosphere is above 32°, except on foggy days.

DECAYING CUCUMBER PLANTS (*Sunnylands*).—Most likely the roots have been kept too hot and too dry in this dull sunless weather. We have examined such Cucumbers and found the soil some 6 inches from the surface like so much ashes from beneath a furnace. When the soil and the roots are all right, we have seen such a result produced by a very bright sun for half an hour, after some weeks of dull weather. The higher the temperature in dull weather the more likely would the plants be to suffer. A little shade is useful in such a case.

WASH FOR WALLS AND FRUIT TREES (C. C. E.).—Lime water is made by placing 14 lbs. of fresh lime in a hogs-head and pouring in 10 gallons of water, stirring well up; and, after standing for forty-eight hours, the clear liquid drawn off is lime-water. We have not used this for destroying insects, but we find it the best of all agents for clearing a lawn of worms. We have no faith in its being used to kill the eggs of insects, and we do not recommend it as a wash for walls. We recommend all walls to be washed with fresh lime and soot in equal parts, brought to the consistency of whitewash by the addition of enough boiling urine or strong liquid manure. Apply the mixture hot—the hotter the better, to the wall, and brush it well into every crevice, and if it does not kill the eggs it will seal them up for ever. Lots of soft soap and 8 ozs. of salt, dissolved in a gallon of water and applied hot to the wall, form an excellent wash, and will kill moss and the eggs of most insects. The efficacy of these and other remedies in a great measure depends on the composition being thoroughly brushed in. The trees may also be washed with the latter solution, applied hot, and with a brush, and well rubbed into the crevices, being careful of the buds. It should not be applied hotter than 160°. For winter dressing fruit trees, 8 ozs. of Gishurst compound should be dissolved in a gallon of soft water.

MATHUW'S ELIZA PEAR—MELON MARROW (A Lady Subscriber).—Mathuws's Eliza Pear is the same as Groom's Princess Royal, rich and early, and in season from January to March. The jam made from the Melon Vegetable Marrow is just like that from the Apricot. The seed has been advertised in the pages of this Journal.

RHODODENDRON AND CAMELLIA LEAVES SPOTTED (Ilum).—The leaves sent have the appearance of having been watered frequently, as if by water dripping from the roof, and their pale colour arises from want of light, growth being made at this dull season. Keep the foliage dry, and water the plants whenever they require moisture, and not oftener. You will know when to water by the dryness of the soil. Then give a good watering. The cause of the leaves browning and becoming spotted may be due to the plants being watered once a week and all at the same time; and, each receiving the same quantity of water, some must have more than they require, whilst others have the soil too dry. On examining the Camellia leaf we have come to the conclusion that the drainage of the pots is not so perfect as it ought to be. That, combined with the buds not being formed perfectly through a deficiency of heat in the preceding summer, will be sufficient to account for the buds falling. This evil mainly arises from deficient root-action.

LENGTHENING A GREENHOUSE (Manchester).—The plan No. 2 with the hipped roof would be the most suitable for gaining the objects you have in view. The junction of the sashes or sash-bars would be best done against a ridge-board; and if the house is 30 feet long two iron pillars or rods would support it more thoroughly.

HEMLOCK IN A GRASS-COVERED ORCHARD (A Worcestershire Lady).—We fear there is but little hope of eradicating this pest while you continue to allow the grass to grow for hay. If you could pasture it for one season, and cut off the foliage of the Hemlock frequently as soon as it shows above ground, it is likely that you would succeed in destroying it. We have ourselves a similar case to yours. A piece of ground has been in hay for some years, and being under trees the crop is not an important one, especially as the Hemlock seems to increase rather than diminish, it being only cut when the hay crop is, and that more for appearance than use. Cutting off the tops an inch or so below the surface with a three-spind is a good practice; and if this be followed up during April, May, and June the Hemlock will be much weakened, and but few plants of it will be left for another year, and these would succumb to a similar course of treatment.

WEEDING PINE (J. G.).—A Weeping Pine would be an acquisition, and there is a probability that the seed in your possession, from Finland, if fresh, would produce one. Sow it in about a month hence in sandy tarry loam, in pots, and place the pots in a cool frame.

PLANTING A VINERY (E. James).—We generally approve of the proposed planting of the vinery, but we think your planting at back will be thick, and would recommend not more than five in the first house, and ten in the second. In the early house, instead of three Muscats, we would have one Dutch Sweetwater and one Buckland Sweetwater, or Royal Muscadine, for the early ripening, or as you have Hamburgh, or Front, if you may have fewer Hamburghs at back. In the larger or later house we would not plant four Golden Hamburghs, not because the Grape is not a good one, but it is a little uncertain, and should be cut when ripe. One or two Vines of it would be enough. We would substitute for it and the variety

not named, Muscat of Alexandria, Bowood Muscat, and Muscat Hamburgh. Instead of having two Barbarossa Vines, which are also a little uncertain, one white Grape, either Calabrian Raisin or Trebbiano, would make a good companion. These three and Lady Downe's require a good heat in autumn to ripen them before winter. The plan proposed will do well.

GRAPES SHANKING (L. C. S.).—You do not say whether your Vines are planted inside or outside. We think it is very likely that lighter or copping will prevent the shanking, but not altogether if the roots are very deep. If so, lifting would be the best remedy; but as you want to make sure of a crop whilst effecting an improvement, try what a lighter crop and a more fire heat will do. The strength and vigour of the wood seem to denote more fruit ripeness. We would try the plan you suggest, planting against the back wall, and training down the glass, and allowing the Vines in front to go on until those at back become strong; and to assist them in doing this you must let them have a good portion of light. Then when you replace your present Vines, we would advise you to plant inside; but to have the inside border, however narrow, higher by a few inches than the outside one. Our Vines, to our sorrow, are all planted outside and brought in through the wall, but it is not a good plan. Be sure of drainage, the least stagnant water will cause the Black Frontigan to shank.

FRUIT TREES IN POTS (L. E. Z.).—Your pit or houses in relation at p. 529 of No. 248, being 9 feet in width, your four-foot bed in front would do well for Melons, with two four-inch pipes below the bed and two for top heat, as recommended at page 529; but if you wished to grow Cucumbers in that bed in winter, it would be advisable to have three pipes for top heat instead of two, or if you grow anything that required a great heat in winter. Now to the first inquiry, as to what fruit trees in pots you could grow in a second bed, 2 feet wide, at the back of this house, with no bottom heat, and 4 feet from the top of the bed to the glass, we would reply that you would succeed with no hardy fruit trees if placed at once in a temperature that would suit Melons; nor would the fruit, if obtained, be of much value if you allowed the glass to be pretty well covered with the branches and leaves of the Melons. If, however, you started Peaches, Vines, or Figs in some other places, or in the same place, but beginning below 50°, and raising the temperature gradually to 60°, so as to have Peaches set, Vines showing their bunches, and Figs their fruit, before these plants had a temperature of from 60 to 65° at night, and from 70 to 80° or more with air in sunny days, then the fruit trees would do in the same temperature as would suit the Melons; and the flavour of the fruit would be fair just in proportion as there was an open space of glass over them, and the sun would also shine through the openings between the leaves of the Melons. If you are fond of Figs, perhaps they would be best in such a position. A dozen pots might be placed in such a border. Peaches would require great attention to air-giving. We need not allude to tropical fruit, but the Passiflora quadrangularis would do well against such a wall, and the Melon-like fruit would swell well if care were taken to fecundate the flowers artificially. It would often be well to keep such a house as you describe as a propagating-house and Melon-house alone. Supposing you to sow now, propagating could go on with the heat that would suit the young Melons, and a dozen of plants or so could either be grown in large pots, or at first only half of the bed might be given to them, the rest being kept for propagating; and when the plants were struck they could be set on the back bed to be slightly hardened off. Then if you sowed in April, the Melon plants, say a dozen, could be planted in the back border, which would be warm enough in May and June without bottom heat, and these could be trained down the glass by the time the first crop was ripening and going off. Saw again in the beginning of June, and you could have a late crop in the bed with the advantage of bottom heat. Such a narrow back bed would also be useful for Ferns and low flowering plants that liked heat. As to the second inquiry, we would be satisfied with the clean gravel above the clinkers for bottom heat, and 5 inches from the pipes will be quite enough. We would place no cocoanut fibre between the gravel and the soil, as the fresher it is and the drier it becomes the more will it act as a non-conductor, and keep the heat from rising into the soil. As you have placed brickbats and clinkers around the pipes in an open manner, it is necessary that you should have pipes, say drain-tiles, an inch or 2 inches in diameter, not only for pouring down water, but also allowing air to enter; for if the air round the pipes were thoroughly confined the heat would not be transmitted by it any more than by fire coccoanut fibre.

NAMES OF FRUITS (E. C.).—Glor Morceau. (T. L.).—No Plus Moutis. **NAMES OF PLANTS (M. D.).**—1, Doodia caudata; 2, Asplenium lanceolatum.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending January 20th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

CROOK'S IMPROVED INCUBATOR

The accompanying engraving is a representation of Messrs. Crook's improved incubator, which, though not differing ma-

terially in principle and form from the older apparatus, nevertheless presents some important modifications. To show more clearly what these are it will be necessary to describe briefly the original apparatus. The size known as No. 2 was calculated to hatch 60 hens' eggs, or 84 Pheasants' eggs, was 22 inches high, 15 inches wide, and 11 inches from front to back. The trays of perforated zinc, lined with blanket, were enclosed each in a

compartment all the sides of which, except the front, were hollow, and served to contain water by which the requisite degree of heat was communicated to the eggs. To heat the water, both in the old and improved apparatus, a lamp is employed which burns a highly rectified non-explosive oil, the burner being a brass tube pierced with five of the smallest holes which it is possible to drill, and filled with cotton threads to draw up the oil. In lighting the lamp a piece of burning paper is held against this tube till the vapour from the oil ascends and is lighted. Externally, the water-jacket is covered with blanketing to prevent loss of heat. The new apparatus instead of being closed at the back is open, so that there is always a current of cool air from front to back below the eggs, and these receive the heat principally on the upper side, as in natural hatching.

The alterations and improvements are stated by Messrs.

Crook to have "originated not from any inefficiency in the principle of our former incubator, but to avoid, as much as we are able, those disasters happening through inattention, the results of which are to dry up the moisture necessary to the perfect development of the germ, and destroy the vitality of the chick. To describe our alteration, it will be necessary to say that we are now imitating Nature as closely as possible, by radiating the warmth upon the top of the egg only, and allowing the under side to remain somewhat cool. Your readers will at once see that this is a natural method; and as the germ floats only at the top side of the egg, and remains so in whatever position the egg may be turned, we consider this beautiful provision of Nature to be our unerring guide, and our experiments have proved that this is the correct method for us to apply our heat. We have not in any way altered the configuration of the apparatus; each remains precisely the same.

Crook's Improved Incubator

Artificial Rearing Apparatus.

"The artificial rearing-apparatus, of which the above is a representation, is very simple in its construction, and is, in fact, a mere perfect carrying out of the plan proposed by M. Réaumur, whose works upon the subject of artificial incubation are well worthy of the attention of poultry-breeders. The apparatus is a slanting casing of hot water, with a loose casing of perforated metal, and lined with lamb skins; a lamp is placed at the back end, which keeps up the required warmth for winter use. It is intended that this useful adjunct should be attached to a coop, as represented by the dotted lines in the en-

graving, which prevents the birds from flying on to the top of the apparatus; the oblique construction of the apparatus enables the chicks to nestle comfortably up to the top side, in imitation of Nature, as if the chick were nestling under the hen. There is no warmth applied to the feet of the birds, as we have found from experience that when they are warmed from the floor upon which they rest, they become weak and languid, soon have the eramp, and readily take cold. The warmth in this, as in the improved incubator, is only applied to the top or back of the bird."

RAILWAY CHARGES.

I AM glad to find from "our Journal" of December 26th that others besides myself complain of railway charges. I am not surprised. The only wonder is that we have submitted to the grievance so patiently—another proof, were it wanting, of the endurance of the Anglo-Saxon! Still, we are told, "If you tread on a worm, it will turn," and I only hope we shall "turn" to some purpose. Your correspondent "J. K." suggests some plans somewhat similar to those that have been thought over by myself. As, however, I promised to suggest a remedy, I now fulfil my promise, and must leave my fellow exhibitors to act as they think fit.

Firstly, then, I think that the Poultry Club may justly turn their attention to this subject: their object is the encouragement of poultry shows and of poultry keeping, especially for exhibition. Are the present railway charges likely to increase the number of exhibitions or exhibitors? I trow not. I do not think any of the members would object to some small amount of income being devoted to remedying this grievance; it need not be very large. I would suggest that at the next meeting of the Club a resolution should be proposed (and if I might do this by proxy I should be very glad to propose it myself), declaring the opinion of the Club, that poultry exhibitions would be encouraged, and indirectly railway traffic would be promoted, if it were an established rule on all railways that

unsold birds returning from an exhibition should travel free. Supposing such a resolution carried, and I can hardly imagine a dissentient voice, it could be printed, and forwarded to the head office of the principal railways, requesting an answer; or, to save the expense of printing, I would take upon myself the trouble of writing out the said resolution and forwarding it to the Secretary for his signature; the postage would then be the only expense. I have already written to the Secretary on this subject.

Independently of any such action on the part of the Poultry Club, I am willing to enter into communication with the principal exhibitors of poultry, and sound them as to their willingness to sign a petition to be forwarded to the various railway authorities. Many, perhaps, would kindly spare me some of this trouble by signifying at once to me, under cover to "our Editors," their willingness to join in the requisition. Of course, all this performance must cost some money, and perhaps most exhibitors would scarcely care to entrust their donations to the unknown quantity that I have hitherto been. The amounts, with the consent of "our Editors," might be sent to the office, and to all such helpers I would give "our Editors" perfect liberty to unravel the mystery. To some few I am already known by name, though not personally, and one gentleman, whom I have never seen, a frequent and successful ex-

Libator, after my first letter on this topic, wrote me that he should be pleased to send me £1 towards any expenses I might incur. Perhaps "our Editors" might be induced to assist us by acting as Treasurers.

I may state that glad as I should be to meet any number of my fellow-managers on this or any other subject connected with Poultry, my duties tie me too completely at home.

I hope next week to draw up a form of requisition that I think may form the ground-work, subject to hints from any persons interested in the matter.—Y. B. A. Z.

THE POULTRY BOOK.

In the notice of "The Poultry Book" in THE JOURNAL of P^{ROFESSOR} for January 16th, it is stated that "it is 'The Poultry Book,' published some years since, edited by Mr. Wingfield and Mr. Johnson, re-arranged with additions." We think it right to apprise our readers of this, as Mr. Tegetmeier's name only appears on the cover and in the advertisement, from which they might be led to believe that it is the production of that gentleman." Permit me to state as follows: Messrs. Routledge, the proprietors of the copyright and plates of the original work, having determined to issue a new poultry book, entrusted me with its preparation. Any portions of the old edition which might be serviceable were placed at my disposal. Finding, however, little of the letter-press available, and that such portions as I adopted would have to be so modified, that it would be unfair to render Messrs. Wingfield and Johnson responsible for them, it was determined to issue the work solely under my name. In the part which has appeared, less than three pages of the original matter are retained out of the twenty-four of which the Number consists. How far the quantity of introductory matter thus adapted in proportion much in excess of what will occur in the body of the work can be said to support the statement that this is the original "Poultry Book, re-arranged with additions," I leave your readers to determine.—W. B. TEGETMEIER.

We are obliged by this communication, as it authoritatively informs our readers what "The Poultry Book," by Mr. Tegetmeier, is to be. The name is the same as that published by the Rev. Mr. Wingfield and Mr. Johnson, and the plates are the same. When Messrs. Routledge placed any portions of the old edition at Mr. Tegetmeier's disposal, they could not have imagined that Mr. Tegetmeier would be disposed to commit a wholesale plagiarism. Five (not three) pages of that old edition are included, without any acknowledgement, in the first twenty-four pages.—Ebs.

PROFIT OF POULTRY-KEEPING.

My stock consisted of a *Dorking* cock and three hens, and three *Brahma* hens. The return has been 814 eggs and sixteen and a half pairs of chickens, the latter averaging 7 lbs. per pair when killed, for an outlay, including food, wire and string netting, and all expenses, of £5 5s. 6d. My fowls have only a small run, and except for an hour in the morning, when they are allowed a run in a neighbouring meadow, are constantly shut in. As egg-producers, I find the *Brahmas* give three eggs against two of the *Dorkings*; the latter cannot do without their hour's liberty in the morning, and I think all *Brahmas* would be best where the birds cannot have entire liberty, their quiet behaviour also makes them great favourites with all parties.

The birds should be kept young. My plan is to dispose of the two oldest hens annually, two pullets taking their places; this keeps them at the same average age, and also secures two winter layers at least. As to food, I use barley, barleymeal, catmeal, soaked bread, potato raw or cooked, and plenty of green meat. They likewise have clean pump water, and clean houses. This management will keep the birds in good condition; but to produce eggs they must have, in addition, as many worms, snails, and other small insects as their owner can possibly supply them with. The return of eggs varies considerably in different seasons; for 1864 it was 186, whereas in 1863 it was 225.—J. M. S.

Two Eggs in a Day.—I have a *Cochin* Hen which has performed the unusual feat of laying two eggs in one day. The first egg was laid about 8 p.m. on Sunday morning, and when she went up to roost at 4 she had laid another, thus laying two

eggs in eight hours. I am quite certain of this, for I have only three hens of that breed, and one is sitting. I took three eggs out of the nest on Sunday, and I am positive that there was not any in on Saturday night. The hen is eight months old. Both the eggs were perfectly shelled.—POULTRY.

THE WALSALL EXHIBITION OF POULTRY AND PIGEONS.

THE quality and the quantity also of the specimens entered for this Show very far exceeded the expectations of its promoters. The entries were fully double the number which the most sanguine of the Committee had ever calculated on, and combined with this unexpected result (as so many other shows were taking place simultaneously, or within a day or so), the names of the exhibitors who would compete foretold what proved to be the fact, a very heavy Show. Placed in so unexpected a difficulty, the Committee did all that then lay in their power to accommodate every one; but to find places for double the number of pens in the space calculated for one-half that number, was a problem of no easy solution. The only course was, "it must be done." As being the most accessible pens of any to light, arrangements were made with Messrs. Turner, of Sheffield, for the number required, and their man did all he could to confine the pens within the prescribed space. A large proportion of the pens for the smaller varieties of poultry were consequently overlapped in front some 9 inches, in no way adding interest to the Exhibition; but it was the only resource to save space, and even then the lower tier of pens was actually on the floor of the Guildhall, and the upper ones were so raised above the line of vision that benches had to be provided all round for the Judges, Messrs. Hewitt and Cottle, during the time of making their decisions. As the poultry pens in all cases crossed the windows the difficulty of seeing the birds thus situated was great, and this circumstance tended much to exclude the light from the remainder. The gas, though liberally introduced, seemed only to cause a confused combination of light with extreme shadow, rendering minute inspection impossible alike to Arbitrators and visitors. Mishaps are generally twin-born, and the morning proved wet and lowering, and so the weather continued until past mid-day. It may be said, that no provincial first show ever yet contained so many first-rate specimens; and a like successful result, we are informed, will be fully provided for at future meetings of the Walsall Society. The building, at present only in course of erection (not being yet roofed in), will, by another year, be completed. It is intended to serve as a place of exercise for the district Rifle Volunteers, and will be of ample size to accommodate any number of pens under a thousand, and the light will in all parts be good. This is, indeed, a vastly improved prospect for the future; and, evidently, Walsall will shortly hold a place among the first ranks of local shows, as many enthusiastic exhibitors are to be found among the inhabitants of the surrounding district.

But to the Exhibition itself. A most singular feature was, that of the large number of pens entered, not more than a dozen were found vacant. *Dorkings* were the first class, and a capital collection they proved; they enjoyed the best light in the whole Show. The hens throughout the class showed to great advantage, but some few of the cocks seemed ailing and over-exhibited. One or two of the cocks had the spurs placed outside the legs, which amounts to a positive malformation. The *Spanish* class was indisputably one of the very best that has been met with for a long time, almost every pen being excellent. All the best pens in this variety had, therefore, to be taken to fresh pens, and placed in a full light, side by side, before any positive opinion of relative merit could be arrived at, and the same dilatory process was compulsory with not a few other varieties. Mr. Rodbard's cup pen was marvellously well shown. The Partridge-coloured *Cochins* were good, and splendidly formed; but many of the cocks were ruddy on the breast, and the hens absolutely buff-throated. Mr. Jennison, of Manchester was the cup winner in Buff *Cochins* with his adult pen, and the attraction of the exhibition was considerably increased to the public, by the order of the Committee to take this splendid lot from a dark bottom pen into a light opposite an avenue, to replace another pen, "highly commended," shown by the same gentleman, by which arrangement (after the prizes were awarded) this pen of *Cochins* proved of easy inspection to every visitor. The *Hawburgh* classes were especially good; but they did not show to the same advantage as they do when placed in full daylight. Many of these pens were evidently much injured by over-exhibition, and a pen or two so much so, that they were returned to their owners as unfit to remain in their present diseased state in close proximity to valuable healthy competitors. The *Palombes*, though a limited entry, were excellent in quality. The *Game* classes were among the best in the Show; but these varieties happened to stand among the least blest with the light of day. Mr. Jas. Fletcher, of Stoneclough, near Manchester, took the principal prizes with Brown Reds and Red Piles; some extraordinarily good Black-breasted Reds were also shown. The "Any other Variety" class was exceedingly good. In *Game Bantams* the competition was, as is always the case in the present day if good prizes are offered, of first-rate quality. Mr. John Crossland here stood first with such a pen of *Duckwings* as would do credit to any breeder, nor would they have ever returned homewards had not the price placed on them been

purposely prohibitory. In the "Any other Variety of Bantams" some excellent Cochins, Bantams, Blacks, Whites, Japanese, and tolerably good Selrichts competed.

Ducks were very good, but all varieties competed together. The "Selling" class of nearly fifty pens brought many buyers.

The **Pigeons** were a very good portion of the Show; the Carriers, Pouters, Jacobins, Owls, Turbits, and Barbets especially so. Many of the latter variety, however, proved in sad condition. In the "Any other class for Pigeons the "Siberian Joe" Pigeons, as they are entered by their owner, were again successful. The name by which they now appear is quite a mistake; they are the "Irishlanders," a Pigeon well known and frequently met with years back, but of late comparatively rare. The Siberian Ice (or Snow) Pigeon, if they must be re-named, could not be complained of, though we ourselves doubt their Siberian origin.

A peculiar feature of the Walsall Show, and one highly creditable to its promoters, was the intrinsic value of its nine silver cups, stated as being worth three guineas each. They were all exact counterparts of each other, and we were assured by two highly respectable silversmiths: "They were worth £4 each at least, wholesale, anywhere." May we here suggest that it would be well for some other Committees we could name to become copyists in this particular of real value, as being a change much wanted? The Walsall Committee have led the way in this matter so well that we trust the complaints sometimes arising as to the absolute value of plate prizes will be no longer heard; and we are confident that the competition will be proportionally increased.

As on the day of opening towards one or two o'clock the sun broke out, the Show was well attended by many of the aristocracy as well as by poultry amateurs. On the second day, though the weather was quite unpromising, the Show was also well attended. The Committee were most obliging to all amateurs, and we rejoice in the success of the Walsall first meeting.

DORRINGS (Any colour).—First and Cup, A. Fenton, Crimble Hall, Rochdale. Second and Third, T. Tatham, Kingsthorpe, Northampton. Highly Commended, Mrs. Bailey, Shooter's Hills, Stoke-on-Trent; H. Lingwood, Barking, Needham Market, Suffolk; J. D. Hewson, M.D., Cotton Hill, Stafford. Commended, Mrs. M. Seamons, Hartwell, Aylesbury Bucks; J. Spittle, West Bromwich.

SPANISH.—First and Cup, J. R. Rodbard, Aldwick Court, Wrington near Bristol. Second, Rev. J. de L. Simmonds, Chilcomb Rectory, Winchester. Extra Second, H. Lane, Ashley Villa, Ashley Road, Bristol. Third, A. Fenton. Extra Third, G. Lamb, Compton, near Wolverhampton. Highly Commended, J. Smith, Walsall; E. T. Holden, Walsall; Rev. J. de L. Simmonds; J. Hildick, Walsall. Commended, E. Draper, Pinrose Hill, Northampton; A. O. Worthington, Newton Park, Burton-on-Trent; C. T. Bishop, Birmingham; J. Smith, Walsall; E. T. Holden; J. R. Rodbard.

COCHIN-CHINA (Partridge).—First and Cup, J. Stephens, Walsall. Second, E. Tudman, Ash Grove, Whitechurch, Salop. Third, J. Wood, Brinscall Hall, Chorley, Lancashire. Highly Commended, R. J. Wood, Brinscall Hall, Chorley, Lancashire; "Caxtus," Clipping Norton, Oxon; H. Bates, Yardley, near Birmingham; E. Tudman. Commended, E. Tudman; J. Stephens.

COCHIN-CHINA (Any other colour).—Cup, First, and Third, C. Jennison, Belle Vue, Manchester (Buff). Second, Mrs. Wollerstan, Statfold Hall, Tamworth. Extra Third, H. Yardley, Birmingham. Highly Commended, C. T. Bishop; E. C. Boville, Wellington, Burton-on-Trent; E. Bemrose, New Uttoxeter Road, Derby; T. Tatham; C. Jennison. Commended, J. Stephens; H. Mapplebeck, Woodfield, Moseley, near Birmingham; R. Adams, Handsworth.

HAMBURGH (Gold or Silver-pencilled).—First and Cup, J. Gleave, Church Lawton, Che-le-hire. Second, T. Fletcher, Stoneclough. Third, R. Roy, Skirbeck, Boston. Highly Commended, T. Wrigley, jun., Tonge, Middleton, near Manchester; J. Holland, Chestnut Walk, Worcester. Commended, R. H. Nicholas, Malpas, near Newport, Monmouthshire; R. Sherwood, Claines, Worcester.

HAMBURGH (Golden-spangled).—First and Cup, H. E. Emberlin, Leicester. Second, J. Palmer, Wednesbury. Extra Second, I. Davies, Harborne, near Birmingham. Third, A. E. Wood, Barneside, Kendal. Highly Commended, W. Beestonstone, Brockthorpe Farm, near Walsall; W. Horton, Altrington, near Wolverhampton; J. Palmer. Commended, S. Mills, jun., Caldmore Cottage, Walsall; R. Tate, Green Road, Leeds.

HAMBURGH (Silver-spangled).—First and Third, J. Fielding, Newchurch, Manchester. Second, M. Palmer, Wednesbury. Extra Third, J. Gleave, Highly Commended, A. K. Wood; T. Davies, Belmont Cottage, Stow Hill, Newport, Monmouthshire. Commended, Hon. W. C. W. Fitzwilliam, Wentworth Woodhouse, near Rotherham; Miss A. M. S. Hurt, the Knoll, Littleover, near Derby; Rev. W. Serjeantson, Acton Bunnell Rectory, Shrewsbury.

POLANDS (Any colour).—First, G. C. Adkins, the Lightwoods, near Birmingham. Second, J. R. Jessop, Hull. Highly Commended, E. Smith, Middleton, near Manchester.

GAME (Black-breasted and other Reds).—Cup and First, J. Fletcher, Stoneclough, near Manchester. Second, Hon. H. W. Fitzwilliam, Wentworth Woodhouse, near Rotherham. Third, J. H. Cook, Severn Bank Tannery, Worcester. Highly Commended, J. Fletcher; J. H. Williams, Spring Bank, Welshpool; W. Wainright, Stretton-under-Fosse, near Rugby; J. E. Sheldon, Wednesbury; J. Tyler, Brook House Loughborough; M. Billing, jun., Wood End, Erdington, near Birmingham. Commended, W. Wainwright; J. Jeken, Eltham, Kent.

GAME (Any other colour).—First, J. Fletcher. Second, J. H. Williams. Third, M. Billing, jun. Commended, R. Lambick, Kenilworth.

ANY OTHER VARIETY.—First, F. W. Zarhorst (Crève Coeur). Second, H. B. James (Light Brahma Pootra). Third, R. Loft, Woodmansey, near Beverley, Yorkshire (Sultana). Extra Third, W. Newman, Walsall (Brahma Pootra). Highly Commended, G. Lingard, jun., Selly Grove, Selly Oak, near Birmingham; Mrs. M. Seamons; R. F. Goodwin, Middleton, near Manchester (Black Hamburg); R. H. Nicholas (Chinese Silkies and Black Hamburg); E. Smith (Black Hamburg).

GAME BANTAMS.—First, J. Crossland, jun., Wakefield. Second, T. E. Postans, Brentwood. Highly Commended, J. G. Pearson; J. Skinner, Mairdree Farm, near Newport, Monmouthshire; G. Maples, jun., Waverley, near Liverpool; R. E. Postans; Rev. G. Raynor, Kelvedon Hatch Rectory, near Brentwood, Essex; J. Percivall, Cleat Villa, Harborne near Birmingham; C. W. Brierley, Middleton, near Manchester. Commended, A. Fenton.

BANTAMS (Any other variety).—Cup and First, C. W. Brierley. Second, J. H. Kilner, Wilsey, near Bradford (White). Highly Commended, E. Cambridge, Stokes Croft Road, Bristol; H. Draycott, Immlerstone, near Leeds (Gold-laced); M. Leno, Markyate Street, Dunstable, Beds (Gold-laced); S. Nock, Walsall; T. Davies. Commended, H. Draycott (White); H. E. Emberlin (White); H. Mapplebeck (White).

DUCKS (Any variety).—First, A. Worthington. Second, J. R. Rodbard (Rouen). Third, J. Skinner (Aylesbury). Highly Commended, T. Tatham (East Indian); H. E. Emberlin (Aylesbury); Mrs. M. Seamons (Aylesbury); Rev. W. Serjeantson (East Indian). Commended, Hon. W. C. W. Fitzwilliam.

SELLING CLASS.—First, S. Mills, jun. (Hamburg). Second, Messrs. S. & R. Ashton, Mottram, Cheshire (Poland). Extra Second, T. Tatham (Dorking). Third, E. Smith (Cochin-China). Extra Third, J. R. Jessop (Widgeon Ducks). Highly Commended, R. H. Nicholas (Hamburg); C. Jennison. Commended, J. Hopkins, Walsall (Brahma); T. Gameson, Walsall (Hamburg); R. Dodge, Sheffield (Game); C. Jennison (Cochin-China); E. Shaw, Plas Wilnot, Oswestry (Spanish); E. Smith; I. Bebbie, Walsall (Dorking); E. C. Boville (Hamburg).

PIGEONS.

CARRIERS (Any colour).—First and Second, T. Colley, Sheffield. Extra Second, S. Harding, Fareham, Hants. Commended, H. Allsop, Birmingham; H. Simpson, jun., Whitby, York; W. Massey, Fulford, York.

TUMBLERS (Any variety).—First, E. E. M. Roysds, Greenhill, Rochdale. Second, J. J. H. Stockhall, Broad Green, near Liverpool. Commended, H. Mapplebeck.

POWTERS (Any colour).—First, W. Massey. Second, E. E. M. Roysds. Highly Commended, W. R. Rose, Cranley Hall, Kettering; H. Yardley.

FANTAILS (Any colour).—First, H. E. Emberlin. Second and Extra Second, H. Yardley.

JACOBIANS (Any colour).—First, A. Middleton, Newport, Monmouthshire. Second, E. E. M. Roysds. Commended, H. Yardley.

BARBS (Any colour).—First, W. Massey. Second, G. H. Roberts, Penwortham, Preston. Very Highly Commended, H. Yardley. Highly Commended, H. Simpson, jun.; W. Massey.

TURBITS (Any colour).—First, W. Massey. Second, H. Yardley. Commended, H. Mapplebeck.

OWLS (Any colour).—First, H. Yardley. Second, G. H. Roberts. Highly Commended, E. E. M. Roysds.

ANY OTHER VARIETY.—First, J. J. Stockhall ("Siberian Joe"). Second, J. R. Jessop. Extra Second, H. Yardley. Highly Commended, H. Simpson, jun.; J. Percivall. Commended, S. A. Taylor, Sutton Coldfield (Trumpeters); H. Roberts (Trumpeters); H. Yardley.

SILVER CUP FOR THE BEST COLLECTION OF PIGEONS.—H. Yardley.

JUDGES:—*Poultry:* Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, Birmingham. *Pigeons:* Dr. Cottle, of Paltney Villa, Cheltenham.

The eighth annual Exhibition of the Jedburgh and Border Counties Society was held in the Corn Exchange, Jedburgh, on Wednesday and Thursday, the 17th and 18th inst.

The following is the prize list:—

SPANISH.—Cup, T. Knowles, Aberdeen. Second, H. Beldon, Goitstock, Bingley. Third, A. Cochrane, Perth. Very Highly Commended, A. Ridpath, Gilmot Place, Edinburgh. Highly Commended, —Wallace, Aberdeen. *Chickens.*—First, R. Teabay, Fulwood. Second, A. Ridpath. Third, J. Anderson, Friarshaw, Melrose. Very Highly Commended, W. Paterson, Langholm, Dumfriesshire. Highly Commended, J. Macneil, Edinburgh.

DORKING (Coloured).—First, T. Knowles. Second, J. Anderson, Rutilven House, Meikle, Forfarshire. Third, C. Pease, Southend, Darlington.

DORRINGS (Silver).—Cup, Countess de Flahault, Tullyhann Castle, Perth. Second, D. Hardie, Sorbie, Langholm. Third, J. Elsworth, Campsie Junction, Glasgow. Commended, Miss Milne, Otterburn.

DORKING (Coloured or Silver).—*Chickens.*—First, Countess de Flahault. Second, Lord Binning, Mellerstau. Third, R. Kerrs, Monteviot, Jedburgh. Highly Commended, Countess de Flahault. Commended, D. Hardie. *Pullets.*—First, Countess de Flahault. Second and Third, Miss Milne. Highly Commended, T. Mansfield, Headmanston House; Lord Binning. Commended, J. Jardine, Arkleton, Ewes.

COCHIN-CHINA (Any variety).—First and Third, J. Shorthose, Newcastle. Second, W. R. Park, Abbotnagow, Melrose. Highly Commended, Mrs. Craw, Jedburgh; H. Beldon. *Chickens.*—First and Second, J. Shorthose. Third, Mrs. W. Ford, Hardengreen, Dalkeith. Commended, Miss E. A. Aglionby, The Hollis, Grammer; C. Pease; T. Knowles; H. Beldon.

BRAMA POOTRA.—First, Miss H. Scott, Anerun House. Second, J. Shorthose. Third, C. Pease. *Chickens.*—First, W. H. Fell, Statnine, near Poulton-le-Fylde. Second, Miss H. Scott. Third, Mrs. Craw, Jedburgh. Very Highly Commended, J. Shorthose. Highly Commended, Mrs. Craw.

GAME (Black or Brown Reds).—Cup, J. Brough, London Road, Carlisle. Second, R. Pickering, Carlisle. Third, H. M. Julian, Whitefriarsgate, Hull. Very Highly Commended, T. Mansfield, Headmanston House.

GAME (Duckwings).—First, Messrs. Easton & Mahon, Jedburgh. Second, T. Dyson, Pellon Lane, Halifax. Third, F. L. Roy, Nenthorn, Kelso.

GAME (Any variety).—*Chickens.*—First, J. Anderson, Meikle. Second, D. Hardie. Third, Mrs. J. Turnbull, Brae, Jedburgh. Highly Commended, T. Mansfield; R. Pickering.

HAMBURGH (Silver-spangled).—First, J. U. Sommer, Jedburgh. Second, Mrs. Craw. Third, H. Beldon. Highly Commended, S. C. Noble, Keldal, Westmoreland.

HAMBURGH (Silver-pencilled).—Cup, W. Cheyne, Selkirk. Second, H. Beldon. Third, R. Roy, Skirbeck Rectory, Boston, Lincolnshire.

HAMBURGH (Golden-spangled).—First, H. Beldon. Second, R. Dickson, Selkirk. Third, A. Heattie, Selkirk. Highly Commended, H. Beldon. Commended, R. Dickson.

HYMNION (Golden pencilled).—First, R. Roy. Second and Third, H. Beldon. Highly Commended, J. Mimos, Brownlands, Paisley.

GUM BANTAMS (Any variety).—First, W. F. Entwistle, Otley. Second, G. Turnbull, Dundee. Third, J. Anderson. Very Highly Commended, Miss L. A. Aglionby (Filed). Highly Commended, M. Ballantyne, Sprouton (Duckwing); D. Froomfield, Kelso; Messrs. Easton & Mabon (Black Red). Commended, F. L. Roy (Black Red).

LANTAMS (Any other variety).—First, J. Muirhead, Tranent. Second, F. L. Roy (Silver-headed). Third, J. R. Jessop, Beverley Road, Hull (Black). Very Highly Commended, F. L. Roy (Black). Highly Commended, H. Dryden, Humbarstone, Leicester-shire (White).

GIENE (Any variety).—First, S. Swan, Bush (Toulouse). Second, T. E. Roag, Luton (Toulouse). Third, D. Hardie (Toulouse). Highly Commended, Miss Bell, Marcheleugh (Toulouse); T. D. Sanderson, Magdalen Hall (Chinese); T. Elliot, Hyndhope.

DUCKS (White Aylesbury).—First, A. O. Swan, Everton Bush, Jedburgh. Second, J. A. S. E. Fair, Gillbestongues, Jedburgh. Third, G. Laidlaw, Mervin-law. Very Highly Commended, E. Leech, Grove House, Rochdale. Highly Commended, S. Swan, Bush. Commended, Miss H. Scott.

DUCKS (Rouen).—First, J. Gibson, Woolhit. Second, Capt. Scott, Kirklands, Ancrum. Third, T. Elliot, Hyndhope. Highly Commended, J. Hall, Broombank, Jedburgh; W. Hodgson, Darlington; E. Leach; Mrs. Douglas, Hyndhope.

DUCKS (Any other distinct breed).—First, E. Hutton, Pulsey (Pintail). Second, J. J. Jennings, Bellevue Gardens, Manchester (Carolinian). Third, J. R. Jessop, Hull (East Indian). Highly Commended, T. C. Harrison, Hull (Brown Call); Comtesse de Flahault (White Call). Commended, J. R. Jessop; E. Hutton (Ten).

TURKEY.—*Poult.*—First, E. Leech. Second, T. Mansfield, Headmaning House. Third, T. L. Jackson. Highly Commended, Lord Binning. Commended, J. Muirhead, Tranent; T. Elliot.

ANY OTHER VARIETY.—First and Second, Comtesse de Flahault (La Fleche and Crive Cour). Third, R. L. Ft. Woodmansey, near Beverley, Yorkshire (Sultans).

SINGLE COCKS.

SPANISH.—First, J. Shortrose. Second, T. Knowles. Third, Mrs. Craw. **DOEKING**.—First, Comtesse de Flahault. Second, A. Cochrane, Perth. Third, J. Shortrose.

COCHIN-CHINA.—First and Third, J. Shortrose. Second, H. Beldon.

GAME.—First, Messrs. Easton & Mabon. Second, D. Hardie. Third, T. Dyson. Very Highly Commended, Mrs. J. Turnhill.

HAMBURGH.—First and Second, H. Beldon. Third, R. Tate, Leeds. Highly Commended, Mrs. Craw. Commended, H. Pickles, jun., Earley.

The Silver Cup, to the most Successful Exhibitor, in the foregoing classes, J. Shortrose.

SWEETSTAKE FOR BANTAMS.—First, T. Oliver, sed., Jedburgh. Second, D. Brown, Bridge Lane, Perth. Third, G. Turnbull, Dundee. Very Highly Commended, W. F. Entwistle, Otley; G. Dodds, Crailing; T. Mallen, Sunderland; Messrs. Easton & Mabon. Highly Commended, F. L. Roy. Commended, J. Steel, Kelso; J. Anderson; S. H. Jeffrey, Jedburgh.

SELLING CLASS (Any variety).—First, T. Clensinson, Darlington (Brown Red). Second, J. A. S. E. Fair (Aylesbury Ducks). Third, Mrs. Dickens (Silver Dorking).

COTTAGE'S PRIZES (Any variety).—First, A. Henderson, Dunip, Jedburgh (Dorkings). Second, W. Murdie, Jedburgh (Spanish). Third, A. Stevenson, Cossford (Black Red Game).

PIGEONS.

The Silver Cup given to the most Successful Exhibitor in Pigeon classes, J. Thackray, Petersgate, Hull.

ALMOND TUMBLERS.—First, J. Thackray. Second, F. Else, Westbourne Grove, Bayswater, London. Third, H. Yardley, Birmingham.

TUMBLERS (Any other variety).—First, R. Pickering, Carlisle. Second, H. Yardley. Third, J. Thackray. Highly Commended, J. Bell, Newcastle (Kites). Commended, J. R. Jessop, Hull; T. Knowles.

FANTAILS.—First, W. R. Park. Second, J. R. Jessop. Third, E. Else. Very Highly Commended, W. Veitch, jun., Jedburgh. Highly Commended, H. Yardley. Commended, J. Sharp, Canal Cottage, Johnstone, Renfrewshire.

POWTERS.—First, Second and Third, J. Grant, Edinburgh. Very Highly Commended, J. Grant. Commended, J. E. Spence, Dovecot-house, Musselburgh.

NUNS.—First, R. Laurie, Melrose. Second, W. Veitch, jun. Third, R. Paterson, Melrose. Highly Commended, W. R. Park.

OWLS.—First, R. Pickering. Second, J. Thackray. Third, J. R. Jessop.

TURBITS.—First, R. Thompson, Kendal. Second, F. Keir, Church Lane, Edinburgh. Third, H. Yardley. Highly Commended, R. Paterson. Commended, J. Thackray; R. Pickering; Mrs. Craw.

JACOBS.—First, J. Thackray. Second and Third, H. Beldon. Very Highly Commended, J. Sharp. Highly Commended, R. Pickering. Commended, F. Else.

BARBS.—First, J. Thackray. Second, H. Yardley. Third, H. Beldon. Very Highly Commended, R. Pickering. Highly Commended, Mrs. Craw. Commended, H. Yardley.

ANY OTHER VARIETY.—First, J. Thackray (Swallows). Second, J. R. Jessop (Magpies). Third, H. Yardley. Very Highly Commended, Mrs. Craw. Highly Commended, Mrs. Craw. Commended, H. Yardley.

SELLING CLASS.—First, J. Gow, Kelso (Barbs). Second, R. Thompson. Third, J. Sharp, Johnstone (Black Magpies). Very Highly Commended, A. B. Boyd, Trinity (Monks). Commended, A. B. Boyd (Sheild).

CANARIES.

SCOTCH FANCY (Yellow).—*Cock*.—First, R. Ballantyne, Hawick. Second, J. Kemp, Galashiels. Very Highly Commended, R. Ballantyne. Commended, J. Hervey, Jedburgh.

SCOTCH FANCY (Buff).—*Cock*.—First, J. Kemp. Second, J. R. Thompson. Very Highly Commended, J. R. Thompson. Highly Commended, J. Jeffrey. Commended, G. Laidlaw, Galashiels.

SCOTCH FANCY (Buff).—*Hen*.—First, W. Hardie. Second, G. McMillan, Jedburgh. Very Highly Commended, R. Ballantyne. Highly Commended, J. Hervey. Commended, R. Ballantyne.

SCOTCH FANCY (Yellow).—*Hen*.—First, W. Tinline, Galashiels. Second, J. Kemp. Very Highly Commended, J. Dalglish, Galashiels. Commended, J. Grierson, Edgworth.

BELGIAN FANCY (Yellow).—First, J. Jeffrey, Kelso. Second, J. Kemp. Commended, J. Marshall, Galashiels.

BELGIAN FANCY (Buff).—*Cock*.—First, G. Laidlaw. Second, J. Kemp. Very Highly Commended, J. Dryden, Kelso. Commended, G. Mabon, Jedburgh.

BELGIAN FANCY (Yellow).—*Hen*.—First, J. Kemp. Second, J. Dryden. Very Highly Commended, G. Laidlaw. Commended, W. Tinline.

BELGIAN FANCY (Buff).—*Hen*.—First, W. Tinline. Second, J. Marshall. Very Highly Commended, J. Dryden. Commended, J. Marshall.

FLEEKED CANARIES (Yellow).—*Cock*.—First, T. Darling, Hawick. Second, A. Ferguson, Kelso. Very Highly Commended, R. Rutherford, Jedburgh. Commended, W. Emay, Jedburgh.

FLEEKED CANARIES (Buff).—*Cock*.—First, Miss Clay, Kerchester. Second, J. R. Thompson. Very Highly Commended, J. Kemp. Highly Commended, R. Ballantyne. Commended, Miss Collier, Jedburgh.

FLEEKED CANARIES (Yellow).—First, G. Park, Galashiels. Second, J. Kemp. Very Highly Commended, G. Mabon. Highly Commended, J. Barton, jun., Jedburgh. Commended, A. Ferguson.

FLEEKED CANARIES (Buff).—*Hen*.—First, J. Kemp. Second, J. Hall, Jedburgh. Very Highly Commended, J. Marshall. Highly Commended, Miss Clay; T. Darling, Hawick. Commended, J. Steel, Kelso.

JUNGLES.—*Poultrey*: Oliver Nicholson, Esq., Landport, Portsmouth; and E. Dixon, Esq., Gold Island, Hexham; *Pigeons*: G. J. Maclean, Esq., Morning-side; *Cottages*: J. Broomfield, Esq., Edinburgh.

KENDAL POULTRY SHOW.

The eleventh annual Exhibition was held on the 18th, 19th and 20th inst. The following is a list of awards:—

GAME (White and Pile).—First, H. Thompson, Maiden Hill, Penrith. Second, T. West, St. Ann's, Eccleston. St. Helen's Lancashire. Third, Rev. F. Watson, Missing Hill House, near Kelvedon, Essex. Highly Commended, T. West.

GAME (Black-breasted and other Red).—First, H. Snowden, Great Horton, near Bradford, Yorkshire. Second, T. West. Third, T. Statter, Bury, Lancashire. Highly Commended, A. Fenton, Grimble Hall, Bockdale; R. Wood, Old Huton. Commended, M. W. Stobart, Middleton-on-Clow, Darlington; H. Thompson. Commended, T. Robinson, Uxerston. *Chickens*.—First and Cup, J. Fletcher, Stonecote, Manchester. Second, T. Bottomley, Sapper Lane, Bottom-shelf, Halifax. Third, T. Robinson. Highly Commended, J. Hodgson, Whittington, Kirkby Lonsdale.

GAME (Any other variety).—Prize, H. Snowden. *Hen*.—First, T. West. Second, W. Hodgson, Darlington. Third, H. Snowden. Highly Commended, J. S. Butler, Boulton-de-Fylde. Commended, M. W. Stobart.

HAMBURGH (Golden pencilled).—First, J. Robinson, Garstang. Second, A. K. Wood, Burneside, Kendal. Third, Messrs. Burch & Boulter, Allen Street, Sheffield.

HAMBURGH (Silver pencilled).—First, J. Robinson. Second and Third, A. K. Wood.

HAMBURGH (Golden or Silver pencilled).—*Chickens*.—First, S. Taylor, Ibbotshole, Windermere. Second and Third, A. K. Wood. Highly Commended, J. Robinson; J. Walker, Haya Park, Knareborough.

HAMMOU (Golden-spangled).—First, T. Waring, Preston. Second, A. K. Wood. Third, Messrs. Burch & Boulter. Highly Commended, R. Tate, Leeds; A. K. Wood. Commended, J. Walker.

HAMBURGH (Silver-spangled).—Cup, First and Second, A. K. Wood. Third, J. Robinson.

HAMBURGH (Gold or Silver-spangled).—*Chickens*.—First, J. Robinson. Second, J. Walker. Third, Messrs. S. & R. Ashton, Mottram, Cheshire. Commended, J. Walker; Miss Steel, Handhow, near Kendal.

DONKINGS (Coloured).—First and Cup, J. Cople, Eccleston, Prescot. Second, H. Harvey, Sheffield. Third, T. Statter. Highly Commended, J. Robinson; T. Atham, Kingsthorpe, Northampton; H. Knowles, Liverpool; Hon. Mrs. Howard, Levens Hall, Kendal. Commended, G. R. Smith, Rams-bill Villa, Scarborough; J. Hatfield, Cottingham, Hull; J. H. Wilson, St. Bees. *Chickens*.—First, H. Knowles. Second, Messrs. Gunson & Jefferson, Whitehaven. Third, J. Robinson. Highly Commended, W. W. Kuttledge, Storth End, Milnthorpe; J. K. Fowler, Prebendal Farm, Aylesbury; H. Harvey. Commended, J. Walker.

COCHIN-CHINA (Cinnamon and Buff).—First, T. Stretch, Ormskirk. Second, J. Cattell, Birmingham. Third, H. Mapplebeck, Woodfield, Moseley, Birmingham. Highly Commended, H. Harvey; G. Fell, Warrington; Messrs. Bowman & Fearon, Whitehaven. Commended, H. Tomlinson, Balsall Heath Road, Birmingham.

COCHIN-CHINA (Brown and Partridge-feathered).—First, R. J. Wood, Chorley. Second, T. Stretch. Third, Messrs. Bowman & Fearon. Highly Commended, Miss E. A. Aglionby, The Hollins, Grasmere.

COCHIN-CHINA (White).—First, Miss Biggar, Braes House, Ecclefechan. *Dumfries*.—Second, Dawson, Hopton Mirfield. Third, Rev. F. Taylor, *Chickens*.—First, Second, and Third, R. F. Taylor. Commended R. Smalley, Lune Villa, Lancashire.

SPANISH (Black).—First, Miss Biggar. Second, H. Harvey. Third, Messrs. Burch & Boulter. Highly Commended, G. Robinson, Gelderd's Yard, Highgate, Kendal; E. Brown, Albert House, Sheffield. *Chickens*.—First, Miss Biggar. Second, J. Marchant, Hanson Lane, Halifax. Third, Miss E. Ridpath, Edinburgh. Highly Commended, R. B. Postans, Brentwood, Essex; T. Kew, Dale House, Burton, Westmoreland; H. Harvey. Commended, J. Harrison, Burneside, Kendal; J. H. Wilson.

BEAUM POOTRAS.—First, R. W. Boyle, Galtrim House, Wicklow. Second, J. K. Fowler. Third, H. Harvey. Highly Commended, F. Crook, Vine Cottage, Forest Hill, London; J. Waugh, Castle Hill, Lochmaben, Dumfries; G. H. Roberts, Penwortham, Preston; Mrs. J. F. Smithson, Whitwell House, Chorley.

ANY OTHER VARIETY EXCEPT BANTAMS.—First, J. Robinson. Second, H. Harvey (Silver Poland). Third, Messrs. Gunson & Jefferson.

SELLING CLASS.—First, A. K. Wood. Second, J. F. Harrison, Kendal. Third, R. D. Holt, Orrest Head, Windermere. Highly Commended, T. C. Harrison; J. P. Harrison; B. B. Postans; M. E. Hutton, Pudsey. Commended, F. W. Earle, Edenburgh, Huaton.

SINGLE COCKS.

GAME.—Cup, First and Second, C. W. Brierley. Third, J. Fletcher. Fourth, M. W. Stobart. Highly Commended, T. Statter; Messrs. Bowman and Fearon. Commended, A. Fenton. *Cockered*.—First, A. Fenton. Second, T. Bottomley. Third, J. Brough Carlisle. Fourth, C. W. Brierley

DORKING.—First, H. Harvey. Second, R. D. Holt. Highly Commended, R. D. Holt.

BANTAM (Game).—First, Mrs. A. Monkhouse, All Hallows Lane, Kendal. Second, W. F. Entwistle, Otley, Yorkshire. Third, Messrs. J. & F. Fryer, Snavely near Chesterfield. Highly Commended, W. Hodgson; H. Shun-
nab, Brook Cottage, Southwell, Notts; R. B. Postans.

BANTAMS (Game).—First and Cup, R. B. Postans. Second, H. Mapplebeck. Third, Mrs. Park, Highson Hall, Whitehaven. Fourth, J. Walker. Highly Commended, W. F. Entwistle; Messrs. J. & S. Fryer; J. Shiener, Maindee Farm, Newport. Commended, G. Maples, jun.

BANTAMS (Any other variety).—First, E. Hutton. Second and Third, M. Leno, The Pheasantry, Dunstable. Highly Commended, W. J. Cope. Bantams (Pekin Bantams); C. W. Brierley. Commended, T. Davies Belmont Cottage, Newport.

DUCKS (White Aylesbury).—First and Cup, J. K. Fowler. Third, Miss M. Jackson, Vale House, Garstang. Highly Commended, E. Leech, Rochdale; J. K. Fowler.

DUCKS (Rouen).—First, T. Statter. Second, J. Nelson, Heaton Mersey, near Manchester. Third, —Willison, Kendal. Highly Commended, J. Nelson; Miss M. Jackson; J. Walker; Mrs. J. F. Smithson; Messrs. Ganson & Jefferson. Commended, H. Knowles; T. Robinson; Mrs. J. F. Smithson.

ANY OTHER VARIETY.—First, T. C. Harrison. Second, A. Fenton (Black East India). Third, R. Turner, Crosthwaite, Milnthorpe. Highly Commended, F. W. Earle, Edenhurst, Hynon, Liverpool, (Black East India); K. Smally, Lune Villa, Lancashire; E. Hutton (Brown Call Ducks).

PIGEONS.

CARRIERS.—First, H. Allsop, Birmingham. Second, H. Yardley, Market Hall, Birmingham. Highly Commended, W. Massey, York; A. I. Robinson, Sunderland; E. Brown. Commended, R. H. Artindale, Liverpool; T. Wareing.

ALMOND TUMBLERS.—First, A. I. Robinson. Second, F. Key, Beverley. Highly Commended, H. Yardley; E. Brown. Commended, W. Stalker, Liverpool.

TUMBLERS (Any variety).—First, H. Yardley. Second, W. Stalker. Highly Commended, A. I. Robinson. Commended, R. Thompson, Kendal.

OWLS.—First, H. Yardley. Second, G. H. Roberts.

POWERS AND CROPPERS.—First, A. I. Robinson. Second, W. R. Rose, Crinley Hall, Kettering. Highly Commended, W. R. Rose; H. Saowden; H. Yardley. Commended, W. Stalker.

BARBS.—First, G. H. Roberts. Second, A. I. Robinson. Highly Commended, T. Kew, Dale House, Burton, Westmoreland; H. Yardley. Commended, H. S. Salisbury, The Lawn, Kempsey; R. Thompson.

FANTAILS.—First, R. W. Thompson. Second, H. Yardley. Highly Commended, W. Stalker. Commended, R. James, Kendal; H. S. Salisbury.

TURKITS.—First, R. Thompson, Moresdale Hall, Kendal. Second, H. Harvey. Highly Commended, R. Dodge, Sheffield; H. Yardley; A. I. Robinson.

TRUMPETERS.—First, A. I. Robinson. Second, J. Thompson, Market Place, Bingley. Highly Commended, Mrs. A. Monkhouse; F. Key.

JACOBS.—First, J. Thompson. Second, R. Thompson. Highly Commended, H. S. Salisbury; A. I. Robinson; E. Brown. Commended, R. Dodge; H. Yardley.

ANY OTHER VARIETY.—First, H. Harvey. Second, S. Sherwin, Whitehaven. Highly Commended, T. Young, St. John's Wood, London (Archangels); H. Yardley; J. K. Trenam, Helmsley, Yorkshire. Commended, H. Yardley.

SELLING CLASS.—First, G. Woodley, Thorne, Doncaster (Black Barbs). Second, J. Thompson. Highly Commended, R. Thompson (Spangled Scabians); D. Harding, Middlewich, Cheshire; Miss J. A. Monkhouse, (Carriers); W. Jackson, Bolton-le-Sands (Yellow Muzzles); H. Yardley; W. Massey; J. Thompson; R. Doge. Commended, R. Thompson (Nuns); Miss J. A. Monkhouse; J. Thompson (Turbits).

SPECIAL PRIZE.—First and Cup, M. Thompson, Beast Banks, Kendal. Second, R. Wood, Old Hutton, Milnthorpe. Third, M. Graham, Kendal. Highly Commended, M. Graham. Commended, G. Robinson, Kendal; R. Wood; M. Redhead, Kendal.

JUDGES.—*Poultry:* Mr. R. Teebay, Fullwood, Preston. *Pigeons and Game:* Mr. H. Beldon, Bingley.

great length of limb and feather, and, arranged in a semicircle on the raised platform, constituted quite a feature in the Show; nor must we omit the Powders of Mr. Hayne, who sent six birds of great beauty of feather, form, and length.

The National Columbarian Society was the first, we believe, to encourage the exhibition and fancy of that kind of Pigeon really in use as messengers. The bird now trained for these long flights is a foreign variety, sedulously reared and trained in Belgium, and now adopted in this country. Messrs. Hudson and Betty sent a large number of these birds. Specimens in Mr. Hudson's pens were noted to have flown four hundred miles at one journey.

Near them we saw a large pen of high-flying *Rollers*, birds evidently bred with great care; in markings they were saddle-backed and black-mottled, and their shape denoted great agility and strength. Next were the *Fantails* shown by Mr. Allison and Mr. Else, two large pens of them; birds of the highest merit. We were delighted with Mr. Allison's powder-blue *Owls*, their neatness and colour made them gems. We are still amongst the Toys admiring a pen of Almond *Baldheads*, Yellow *Baldheads*, and *Jacobins* exhibited by Mr. Morris. This good Toy-fancier never fails with his pretty birds to satisfy the critical eye of the fancier, or please the visitor. Mr. J. Percivall showed also Toys, *Jacobins*, *Archangels*, Short-faced birds, and some resplendent Blue *Dragons*. As we look at them we cannot recollect any to surpass them. We next have to notice a pen of *Almonds*, *Agates*, and some other of the thirty-two modifications of colour (all of which may be found in an Almond stud), the property of Mr. Merck, and some very good *Almonds* and *Kites* shown by Mr. Park.

Returning to the Barbs, represented by a superb collection, Mr. Dart had some very good birds, *Yellows*, *Blacks*, and *Reds*. Mr. Jones filled a pen with twenty magnificent birds, besides showing others singly and in pairs; among them were birds of singular excellence, being models of perfection. The pigmy Powders of Mr. Tegetmeier are a novelty. They are very interesting, showing all the properties of our old Powder reduced to a minimum; still they have the properties of an elegant Powder, and may become favourites here as they are in the Emerald Isle.

Mr. Walker's pen of *Almonds* and *Black Mottles* were birds of great value and in high condition. We admired Mr. Esden's pretty Blue Beards, Mr. Else's *Trumpeters*, and then reached Mr. Wiltshire's contribution, eight full-propertied Black Carrier cocks, magnificent birds, and by themselves an exhibition. Lastly we have to say a word on the *Almonds* shown by the Chairman of the Society, Mr. Jayne. They filled a large pen, were such as Mr. Jayne's birds are well known to be, and the old connoisseurs of this Pigeon pressed round the pen to admire their favourites.

We understand the Society intend holding their next Exhibition during the cattle show, in December, for the convenience of country fanciers. We have no doubt it will be an event in even that busy week.

(From a Correspondent.)

The annual grand Show of the above Society was held at the Freemasons' Tavern on Tuesday last, when both members and visitors mustered in strong force. On the whole, the show of Pigeons was of a marked and superior character, indeed we scarcely remember seeing the pens so well and so numerously filled. Messrs. Hayne and Bacchus showed a collection of *Powers*; Mr. Hedley, *Carriers* and *Barbs*, among which were some good specimens. Mr. Betty, the Secretary of the Society, had a small pen of *Archangels* not quite so bright in colour as we should like to see. Mr. Jones exhibited *White*, *Red*, *Yellow*, and *Black Barbs*; many of them very good in eye, but somewhat long in the face. Mr. Hudson showed his stud of homing birds, some of which have been at Winchester, Southampton, Salisbury, &c. Mr. Percivall exhibited a pen of *Dragons*, which were greatly admired for their sound colour and fine form; also a pen of Short-faced *Tumblers*, *Baldheads*, *Archangels* (first prize at Birmingham), &c. Mr. Esden's *Beards* and *Black Mottles* were much noticed, both specimens being very good; and an exceedingly pretty pen of *Almonds* and *Black Mottles* was exhibited by Mr. Walker. The Carrier class was unusually well represented by Messrs. Else and Faith, the first-named gentleman especially showing some very fine birds; a young *Dun* hen in particular was deservedly admired. Mr. Allison's *Fantails* were good, but hardly up to what we have seen on former occasions. A pretty pen of *Baldheads* and *Jacobins* was sent by Mr. Morris, the *Red* and *Yellow Baldheads* were very neat and good. We are pleased to find this Society so steadily progressing, and heartily wish them that success they so fairly deserve.

DOTTINGS AT NEWPORT.

HAVING been myself present at the last Show at Newport, I beg to endorse all that "Y. B. A. Z." has said in the last Number of "our Journal" as regards the size of the exhibition pens, or, more properly speaking, baskets. There was scarcely room in many of them for the birds to turn round. In some the cock birds could not stand erect without injury to their combs, and the tail plumage, both of cocks and hens, was sadly disfigured. The baskets for the single cocks seemed in most cases suffi-

THE NATIONAL COLUMBARIAN SOCIETY'S EXHIBITION.

THIS Society invited the public on Tuesday to their annual Show, held in the Masonic Hall of the Freemasons' Tavern. We congratulate the Society on the great interest their Shows have attracted, and on this occasion the Exhibition called forth loud expressions of surprise and commendation from every one. The hall was filled with lines of pens, and contained more than 1500 birds, around which circulated from two to six an unbroken succession of visitors.

On entering the Hall we noticed on our left the *Carriers* of Mr. Hedley, fine specimens, shown singly, and well worthy of the distinction. Next came his *Barbs*, birds of rare quality; continuous with them were placed the twelve *White Barbs* of Mr. Jones, the best collection of Whites we ever saw together; the rich-coloured eye wattle, large and round, was seen to perfection on the snowy-white ground; then Mr. Else's *Carriers*, birds that have held their place in so many prize lists. Next we come to a diminutive bird, the *Black Mottles* of Mr. Esden. We were delighted to see this old fancier of *Beards* and *Mottles* so successfully keeping before our eyes that prettiest of *Tumblers* the *Black Mottle*, which had threatened to become extinct. We next noticed the *Carriers* of Messrs. Ord, Faith, Feltham, Allen, and Edmonds. As these gentlemen exhibited about two hundred birds altogether, we must pass these over in more general terms than they merited. Mr. Ord showed *Whites* and *Blues*, two *Blue hens* in a round pen, perfect in style and symmetry, the flowers of the flock; Messrs. Faith and Feltham, *Blacks* and *Duns*; Messrs. Edmonds and Allen, *Blues*. A host of *Powers* shown by Mr. Bacchus were birds of

ciently large, but when there were three large Dorkings or Cochins together, the space given was miserably insufficient. It is a pity that so well-ordered a Show should lose exhibitors from such a cause as this, which might be prevented at no very great outlay. No doubt when the attention of the civil and attentive Secretary is directed to the subject, he, under Lord Tredegar's auspices, will remedy the evil.—A. K. C.

TRIMMING COMBS—VULTURE HOCKS IN COCHIN-CHINAS.

On the authority of one of our most able poultry judges, I find by your Journal of the 9th inst. that it is not considered unfair to trim slightly the combs of Cochins and of Spanish, and that it is a frequent practice to cut, or, what is more difficult of detection, to pull out the feathers in vulture hocks. If I understand the object of poultry breeding, and poultry shows rightly, it is to improve the breed and natural condition of birds by care and judgment in the selection of stock, and not by the use of "the razor, a sharp knife, or scissors." The only exception that can be made to this, is with Game, which, as long as we breed for fighting-points, must come under surgical operation.

In the name of common sense and common honesty let judges at once not only "turn the scale" against, and disqualify and publicly denounce, all persons practising imposition; for if we are to purchase prize birds at enormous prices for the improvement of our stock, and to avoid certain defects, it is nothing less than a swindle to have paid for those birds in which the defect has been artificially hidden, but can be reproduced in the next generation. If this matter be not stringently dealt with, purchasers at shows will become rare, and shows themselves will be simply competitions where the greatest rogue wins, and scissors tell better than breeding.—EGOMER.

SIBERIAN ICE PIGEONS.

Your report on the Manchester Show contains a mistake in the name of my Pigeons, which have won the first prize under "Any other variety." Not "Siberian Joe Pigeons," but "Siberian Ice Pigeons" is the correct name. Since, also, another journal contains the same mistake, I am led to believe that either my entry of the birds must have been misread, or a misprint must have occurred in the catalogue. The "Siberian Ice Pigeons," also called "Porcelain Pigeons," owing to their plumage having a resemblance with the white cream-colour of china, as it is used in the East, come from the extreme east of Siberia, from the peninsula of Kamtschatka, where they abound and thrive during the severest winters. Kamtschatka produces also White Geese of enormous size, with long curls and laced wings, which give them the most striking appearance. Kamtschatka fowls are black, their feathers and spangles being turned upwards in graceful curls. The cock has a collar, standing upright like the old-fashioned Stuart collar, and his comb, being 4 inches in length, 2 in height, and 1 in breadth, has a serrature of no less than forty-six tips. I received some specimens of the above, together with Siberian Ice Pigeons, and I intend to exhibit them after this spring's breeding season.—FRANCIS BRÖMMEL.

TURKEYS.

Your remarks as to the advance made by the various breeds of poultry within the past twelve months are, no doubt, strictly true. The prizes affixed to the various pens in the late shows, and the number of pens "claimed" at high figures, are a proof not only of this, but of the rapid advance poultry-breeding is making in public estimation. Perhaps among the competing birds none have surpassed Turkeys, two pens of which were claimed at Manchester at £15 and £20 each. Whether you regard form, size, weight, or plumage, the birds of this year are a great improvement on those of last. The object of my letter is to endeavour to remove some of the restrictions and disadvantages under which this highly favoured race labour. Considering the cost of railway carriage to and from the shows (often amounting to 10s. or 15s. each way), the prizes offered are too small. The clumsy mode of weighing the birds when judging them is simply barbarous; instead of weighing them in their cages they are pulled and hauled out by rough hands, and often much injured in their plumage.

One of the primary objects of exhibitions is to give persons an opportunity of selecting suitable birds for breeding purposes. This would be better accomplished if, instead of calling for a pen of one cock and two hens, or even of one cock and one hen, the managing Committees would call for pens of "single cocks," and of a pair of hens or poults. We do not want to breed in-and-in, but to cross. Considering the high prices now asked for good birds, it is absurd to compel a purchaser to take what he does not want, and what another would be glad of. The pens provided for Turkeys at many of the shows are much too small.—DELTA.

B. & W.'S APIARY IN 1865.

1. ACTIVE operations commenced in my apiary on the 15th of May, when I made my first swarm by driving the pure Italian queen (Mr. Woodbury's), with all the fully developed bees, out of c. Saw and caught the queen, and was pleased to find that the workers were all well-marked Italians, as last year. There were many drones, and much worker brood; no royal cells tenanted. The deserted stock was next put in place of r, which in its turn was shifted to a new apiary in my fowl-house. It is there lettered k. r gave me 25 lbs. of honey-comb; c, 10 lbs.; and r, 3 lbs. On the 3rd of June r swarmed naturally and in great force, with its young Italian queen, and was bived (p) in the fowl-house. Strange to say, however, both r and p show great impurity of breed, there being very few yellow-jackets among them. How is this to be accounted for? Last year every queen that I raised artificially out of c became the mother of a host of more or less beautifully marked Italians. This year not a single queen out of the same stock, and evidently from the same mother, has turned out well.

2. A natural swarm issued five days later from r. It had many beautifully-marked Italian bees, but the stock out of which it issued has since lost almost all traces of Italian blood. It was put into a Tasmanian hive (m), and gave me 14½ lbs.

3. A natural swarm came off from z on the 22nd of May, equally beautiful as to colouring of bees. After living, it flew off to a hollow tree at some distance. It was finally recovered, as detailed by me in THE JOURNAL OF HORTICULTURE last July, and located in a new box in place of the mother stock, which I transferred to the fowl-house. The latter (s), now degenerated, swarmed again naturally on the 6th of June, but was returned, and gave me 11¼ lbs. of honey. The first swarm, v, yielded 14 lbs.

4. The same day, made another artificial swarm out of c, by taking off a small super full of eggs and larva, and substituting it in place of a, which was also moved (now o) to the fowl-house. The swarm gradually died away, having failed to raise a queen. The bees worked hard, however, not having apparently detected their loss, and gave me 10 lbs. in supers, besides a quantity of honey in the super-stock itself, which I gave to a neighbouring hive taken in the season. o yielded 15½ lbs.

5. June 3rd. Besides the swarm which issued from r to-day, I found a small swarm on an espalier in my garden. Many of the bees were Italians. Out of which hive it came I am ignorant, but I suspect it issued from a, which had been piping the same day. This stock (t) is doing well, but it only half filled a largish box with comb.

6. June 4th. To-day two second swarms came off from a and p. The former returned to the hive; the latter was bived in a large box lettered q, and has done pretty well, about half filling the box.

7. June 5th. Two second swarms issued from a and o. The former was put into a box lettered n. Being a very small swarm it was very light in September, weighing about 5 lbs. nett. The swarm out of o was returned to its hive. a yielded 14 lbs., besides the two swarms, t and n; v yielded 32 lbs. of comb. r also gave 26 lbs., and was then presented to a neighbour. g, too, gave 21 lbs.

8. The last operation I have to record was the substitution of the young pure-bred Italian received in October from Mr. Woodbury, in place of one of my English queens. After driving the populations of a and r, and destroying their queens, the bees of both hives were united together, and located in place of a. The young queen was then gradually and successfully introduced to the united-bees, without any semblance of anger or irritation on either side, by the aid of a minute box with glass sides, kindly presented to me by Mr. Woodbury for the purpose. The plan pursued was simply to put the queen in this box with half a dozen of her own subjects, and then to

set them over a hole in the crown-board of A, with a piece of perforated zinc intervening. As soon as the scent of the lower hive had well ascended into the little box, a bee was allowed to ascend from time to time, until it was deemed safe to withdraw the zinc slide altogether. In twenty-four hours queen and all had descended into the lower hive.

The following is the present condition of my apiary lettered according to the foregoing statement :—

BEE-HOUSE.		
A. Pure Italian queen. Born 1-65. Had from Mr. Woodbury. Strong in bees.	B. Defunct.	C. Pure Italian queen. Born 1862. Had from Mr. Woodbury. Very strong in bees and honey.
D. Degenerate queen. Born 1865. Strong and rich.	E. Pure Italian queen. Bred out of C in 1864. Strong and rich.	F. Degenerate queen. Born 1865. Strong and rich.
UNDER COVER.		
G. Pure Italian queen. Bred out of C in 1863. Strong.		
GARDEN.		
H. Abolished.	I. Hybrid Italians. Strong.	L. Pure Italian queen. Bred out of C in 1864. Very strong and rich. Tasmanian hive.
M. Pure Italian queen. Born 1-64. Bred out of C. Very strong and rich. Tasmanian hive.	O. Degenerate queen. Born 1865. Strong.	N. Degenerate queen. Born 1-65. Rather weak.
FOWL-HOUSE.		
P. Degenerate queen. Born 1865. Strong and rich.	Q. English queen. Born 1864. Strong and rich.	
K. Degenerate queen. Born 1865. Very strong and rich.		

—E. & W.

APIARIAN NOTES.

THE above heading recalls to my mind the name of a worthy gentleman and frequent contributor to the columns of this periodical, both long ago when it was known as THE COTTAGE GARDENER, and of late years since it has received the name of THE JOURNAL OF HORTICULTURE. For a great number of years Colonel Newman frequently detailed his observations and experience on bees and other scientific subjects, and was very partial to the title of "Apiarian Notes" as the heading of his papers on the former topic. I had not the honour or pleasure of personal acquaintance with Colonel Newman, but having received more than one courteous invitation from him to pay him a visit at his residence in Cheltenham, I promised to do so when opportunity might offer. For some years I was unable to find any such opportunity; but in September of the past year, having gone up to Gloucester to attend the grand Choral Festival, I proceeded to Cheltenham for the purpose of paying the long-intended visit to Colonel Newman. I had not previously written a note signifying my intention, but trusted to the chance of his being at home. On inquiry I was informed, to my very great regret, that he had died a few weeks previously. We must all feel more or less sorrow when any well-known contributor to the pages of our pleasant periodical passes away, and when we consider that the name once so familiar to our sight must henceforth cease altogether to appear. But I must proceed to the more immediate subject of this article, which is intended to be an epitome of my apiarian doings of last year.

The winter of 1864-5 was rather a trying one for bees, from the long period of confinement to which they were subjected owing to the cold weather. Fortunately the majority of my hives, as well, I believe, as of those of most of the cottagers in the neighbourhood, contained ample stores of food, the result of a first-rate honey harvest in the previous summer. Not a single stock in my apiary received, or at all stood in need of a single ounce of artificial food, either in the autumn or in the spring. I was, however, very sorry to see that the bees of several of the hives were attacked by dysentery of a very virulent character. Twenty-two stocks had been made up in the previous autumn for the winter and succeeding summer campaign, out of which number four had been lost from dysentery, death of queens, and other causes. Of the remaining eighteen hives in March and the early part of April, three were suffering from dysentery. The bees in each of these diseased hives were far from numerous; but, as I have frequently noticed under similar circumstances, the quantity of brood was very considerable, appearing to be much more than the very reduced population could by any possibility cover for the purpose of

hatching out. These affected stocks being in frame hives, I removed all the combs in each, with the exception of three or four which contained brood and eggs or sealed honey. At the same time in two of these hives I examined the combs to see which possessed the most apparently prolific queen. There seemed to be a slight difference in favour of one, but she laboured under the disadvantage of being a year older than the other, which was her own daughter, so her fate was sealed, and with sure but reluctant hand she lay crushed and lifeless. The combs which had been selected were restored to their respective hives, being inserted in the centre, leaving the sides vacant. The bees were allowed to settle quietly in their own domiciles, and were left undisturbed until the next day. Then, after gently taking off the cover, I removed two of the combs in the box which possessed its own queen to the next notch, leaving a space for one frame to be slipped down between. I took out one of the frames containing most brood from the queenless stock, with the bees peaceably clustering over the surface, and inserted it gradually in the vacant space adjoining one of the principal brood combs in the other hive. Then a second brood comb was similarly dealt with, being placed on the other side of the two central frames. The third comb having some eggs was made to take the situation of one of the four, which contained only sealed honey. The remaining space was filled up by a frame of clean worker comb, which had lain wrapped in paper during the winter. From the two stocks nine of the sixteen combs were abstracted, and were condemned to be burnt, owing to their filthy condition. The cover being replaced on the now-united colony, quietness was soon restored; hardly a death from fighting or otherwise resulted. The increased vigour with which the bees went to work augured well for the future, and, as will be seen, I had no reason to regret the step taken.

There was yet but one other affected stock, which it did not please me to retain, and I resolved to unite the bees and brood combs to its neighbour, a tolerably populous and well-supplied colony in a ten-frame hive. All the combs were removed but two, the queen destroyed, and spaces made by removing the two end frames and shifting some of the others to the side, so as to leave vacancies for the insertion of the two frames. In this instance I did not make the delay of one day, but as soon as the bees were tolerably settled completed the operation, and with success equal to the former. In this case also the union was fraught with very evident advantage, the stock quickly becoming one of the most populous in my apiary.

In performing these unions I never fear any failure in the spring; the bees appear less disposed to resent intrusion, and are altogether more peaceably disposed than at a later date. As a general rule, it is advisable to allow a day to elapse after the preparation of the hives and the destruction of the queen of one of them, before the union of combs and bees is attempted. Care must be taken to put all the combs containing larva or eggs together in the centre, otherwise, if separated, there may not be a sufficient number of bees to cover them, consequently, considerable loss may take place. I cannot help repeating the advice which I have more than once given when relating the history of "My Apiary" from year to year, of making it a rule always to unite two or more weak stocks together, or a weak stock to a more populous one, in the spring. I have almost invariably found hives so strengthened answer remarkably well, whereas if all the weak stocks had been retained singly they would, probably, have utterly failed in doing anything for their owner during the entire summer.

The season, which commenced with a very backward and unpropitious spring that seemed to try to the utmost the powers of the best stocks, suddenly changed to one of a very different character: a first-rate honey harvest, which set in early in May, induced extraordinary activity throughout the entire apiary, and so great was this activity, that it was difficult to believe that it was exhibited by the same hives which only a fortnight previously had presented such an appearance of scanty and unthriving populations. So suddenly and unexpectedly did this propitious change make its appearance that a mishap, which might easily have been prevented, resulted in the case of several of my best stocks. It has been my custom, previously to making up the hives for the winter, to remove from the large ten-frame boxes a frame, with comb, on each side, leaving the spaces unoccupied. This is done to prevent these combs from becoming mildewed, and to afford more space for air. The removed frames are wrapped up in paper, and put securely away until the spring, when they are restored to their places. Unfortunately, before I thought that the bees could have com-

menced comb-building, or required the accommodation of these frames, they had, in almost every instance, constructed very large combs, which were pendent from the top boards. These, though full of eggs or honey, it was necessary to remove in order to put on the adapters for supering the hives. Few of them could be made available in the same hives, consequently the bees suffered a considerable loss of time and resources. I now discovered that the super accommodation ought, in most cases, to have been supplied a week or ten days previously. I have good reason for believing that this mistake cost me some hundreds of pounds of honey. Nevertheless, such was the excellence of the honey harvest that suddenly took the place of great scarcity, that supers, when put on, were immediately taken possession of, and comb-building progressed with marvellous rapidity. In some of the hives an injurious effect had accrued from the delay in affording additional room. Honey being so abundant the bees stored it in every available cell, trenching upon the space required for the brood; consequently the queens were, to a considerable extent, restricted in their deposition of eggs. This evil was, however, in some degree remedied; after additional accommodation had been afforded the honey was removed, and was probably made available in the secretion of wax. I trust that the experience thus gained will not be thrown away upon me, and that in future all supers may be in their proper places rather before they are really required than after.

I purpose giving an outline of the general results of my apiarian operations for the season, but as this paper has already extended to a considerable length, I must defer its continuation until another week.—S. BEVAN FOX, *Exeter*.

DROPSY IN BEES.

THE "DEVONSHIRE BEE-KEEPER" is a high authority on all apiarian subjects, and I have the utmost respect for his opinions, but he will excuse me for thinking he has fallen into a mistake in characterising as dropsy the disease which he has described at page 534 of the last Volume of the Journal. To me, the complaint with which his bees were afflicted in 1861 appears to have been just dysentery in an aggravated form, or, rather, dysentery in its second and subsequent stages.

In the mild climate of Devonshire, where pollen can be gathered on Christmas-day, the period during which bees are confined to their hives is comparatively short, and, consequently, the malady with which we apiarians in the north are frequently visited seldom makes its appearance in the sunny south; but even there the winters are occasionally cold—the thermometer in January 1861 having registered as low as 7° on the surface of the ground, and 12° at a height of 4 feet above it. The seasons, too, I have no doubt, sometimes prove wet, and if continued moisture prevent bees that would otherwise be active from leaving their homes for a considerable length of time, the consequences must necessarily be pernicious. Retention of the bees beyond comfortable endurance not only induces dysentery, but, by vitiating the humours of the system, generate other evils, which manifest themselves in the watery plethora described by Mr. Woodbury. The collection of water, though not confined to them, is yet most abundant in the colon and receptacle for the feces, and is discharged in the same way as other evacuations.

It was only last winter that circumstances led me to put one of my hives into an unusual state of activity, whereby a considerable consumption of food was the result. The weather for two months afterwards proved wet, cold, and stormy, positively forbidding the bees to leave their dwellings; of those that ventured out only a few were able to return. The result, as might have been anticipated, was disastrous, for the whole colony, amounting to 4000, being tried beyond endurance, succumbed to the cold. Unable to take additional food into their stomachs, they could no longer keep up the necessary warmth, and every bee, not excepting the queen, was swollen to a great extent. I tore up many of the most enlarged, and found them charged with dark fetid feces or a semi-transparent acrid fluid. The identical disease, I imagine, is referred to by Bonner in his "Treatise on the Natural History and Management of Bees." At page 102 he says "Suffice it, therefore, to observe in general that long confinement is prejudicial to the bees, and that, as they do eat a little during their confinement, it is necessary they should get out to void their ordure. For I have seen bees in some hives that have been long confined swelled to such a size for want of such opportunities, that they seemed

larger than a queen bee; and when they did at last get liberty to go out of their hives, being unable to fly, they would fall over the edge of the stool, and creep on the ground till they died in great numbers, so that scarce one of a dozen of them ever recovered." *Vide* also page 106, 107, and 108.—R. S.

It is certainly possible that "R. S." may be right, and that the disease which, in page 534, I hypothetically denominated "dropsy" may be merely the last stage of dysentery. As my only object is to elicit the truth, and add, if possible, to our store of apiarian knowledge, I have to thank him for his contribution, and would invite others who have had experience of the diseases of bees to follow his good example. I do not claim for our Devonshire bees entire immunity from dysentery, but I do think they suffer less from it than bees kept further north. The question I am desirous of submitting to the apiarian readers of "our Journal" is, whether the disease which I have described under the name of "dropsy," which, be it remembered, attacks queens as well as workers, and which the finest summer fails even to mitigate, is identical with that which we have so long known under the name of "dysentery?"—A DEVONSHIRE BEE-KEEPER.

DRIVING BEES.

IN THE JOURNAL OF HORTICULTURE, No. 248, I find the subject of driving bees through the bars referred to. I have driven them both ways; but if "J. A." is not accustomed to driving I would say, Invert the hive, as the fact of turning the hive seems to set the bees in motion, and they run about as if to find out what is the matter, then a few minutes' driving generally puts all right. On the other hand, by lifting off the crown-board and driving they are very slow in leaving the hive, running over the bars and down again several times, and a great many make for the usual opening of the hive. If "J. A." take off the crown-board quietly and look very closely between the combs he may catch sight of the queen, if so, let him take a strong feather and lift her into the empty hive, carefully watching that she do not go back again; then a few raps under the hive and he will find the bees leaving very fast. I once succeeded in this way in taking the bees from a glass-hive that I was most about. My experience of driving has been with wood, straw, and glass hives; but I always take advantage of a fine, hot day, and I have only attempted the operation in the autumn.—TIPPERARY BEE-KEEPER.

OUR LETTER BOX.

BUCKWHEAT (*G. R. S.*).—It is not such good food for poultry as barley, and bread-crusts are better than either for them.

INTERNAL ULCERATION (*W. R. P.*).—The symptoms you particularise indicate internal ulceration. We cannot give you a better reply than the following extract from "The Poultry Keepers' Manual," which we have just published:—"ULCERATION OF LIVER OR INTESTINES.—If a fowl mopes, with its neck drawn within its shoulders, droops its wings, has pallid comb, wastes, and finally diarrhoea set in—the probability is that it has ulcers in its liver, or intestines, or in both. There is little or no hope of saving a fowl thus diseased. Bread soaked in ale should be its chief food, but we know of no medicine that is beneficial."

BARB PIGEONS AT THE ABERDEEN SHOW (*J. R. R.*).—We have received your complaint, and have made inquiries, and cannot discern that you have any ground for complaining against the Committee. They have no right to interfere with the Judge's decisions unless fraud of some kind has been practised. The Powder cock you have received and is not your own, we advise you to keep until either the Committee or this notice brings an owner for it. Any delay in answering your letter, we are informed, was occasioned by the Secretary's absence.

EXCESSIVE ON COCHIN COCK'S COMB (*Subscriber*).—If only a wart, and an accidental excrescence on the comb of your Cochin cock, we do not consider it a disqualification; but, if it be a sprig growing on the side of it, it is a grave disadvantage. It is by no means uncommon, and it is generally cut off when the birds are young. A light Buff hen does not match with a Cinnamon cock. Cinnamons have not been encouraged of late, nor do they seem to be understood as they were formerly. There are dark and Silver Cinnamons.

SPANISH COCK UNWELL (*Spanish Cock*).—Your bird, with copious discharge from his mouth, is suffering from severe cold. In any other breed it would end in rump, but Spanish are not subject to it. He must be purged with castor oil, a table-spoonful every other day, and fed on bread steeped in ale. He will soon be well, and you may breed from him safely.

FLOOR OF POULTRY-HOUSE (*Nemo*).—We have found road-crit the best bottom for fowls pens. It is light and soon dries after rain. But for this, we hardly know what we should have done during the long wet weather. It is composed of scrapings and the trimmings of the sides. We pay 4s. per one-horse cartload. It is mixed up with grass, and it is wonderful to see how the fowls delight in it.

BOOK (*Eboracum*).—We cannot tell what a publication will be. The editor is not a first-rate authority.

MOULDY COMBS (*W. W. W.*).—The few remaining bees having been expelled and united to another stock, the mouldy combs should be put in a dry place and kept there until wanted for use. Much of the mildew may then be removed by lightly brushing their surfaces with a soft brush, and the bees themselves may be safely trusted to deal with the remainder.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 44.4°; and its night temperature 31.7°. The greatest heat was 57°, on the 1st, 1852; and 3rd, 1850; and the lowest cold 8°, on the 31st, 1857. The greatest fall of rain was 0.75 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

THE COIL SYSTEM OF PLANTING VINES.

IN a recent Number of THE JOURNAL OF HORTICULTURE Mr. Rivers has recommended this system of planting Vines, and a woodcut was given to illustrate more clearly what he wished to inculcate. Knowing that there are various opinions held by experienced cultivators on the coil system of planting the Vine, I fully expected that some of your numerous correspondents would ere this have referred to the matter; but as it has been so far passed over, and the season is drawing near when Vines are generally planted in great quantities, I have ventured to address my mite in respect to this not-unimportant subject. It is a common proverb that "a bad beginning often makes a good ending;" but in gardening, as in most other undertakings, this is the exception and not the rule. I approach the subject feeling that whatever so acute a man and so experienced a fruit grower as Mr. Rivers advances is worthy of being listened to with that deference and courtesy which his long years of experience and observant eye deserve.

The coiling of Vines, as many are aware, is by no means a question of yesterday. It is a method which caused a goodly amount of discussion many years ago. Whatever can be said in its favour or against it, it is easy to suppose that to the inexperienced eye it presents not an unfavourable aspect, but one which is striking and specious; and if incorrect in principle—opposed to the laws and functions of the Vine—it is, therefore, all the more dangerous. I may at once avow that I consider it incorrect in theory, and have found it not only useless in practice, but to some considerable extent prejudicial to the well-doing of Vines, especially for some years after they are so planted. However, I would not even on that account pronounce indiscriminate censure on Mr. Rivers's woodcut. At the same time it must be admitted that we are very apt to follow a leader without even calling in question the correctness or reasonableness of a path in which he leads us as the nearest route to perfection or success.

In the first place, I object to coil planting because I think it opposed to the unerring laws of Nature to bury that portion of a plant or tree in the earth which was designed to be above ground. It must be considered very unnatural to bury the stem of a plant in the ground, and the evil consequences of doing so have, doubtless, been clearly illustrated in the experience or observation of many. This is too often the case where earth has been carelessly heaped up against the stems of trees to the depth of only a very few feet. I have seen numbers of trees absolutely killed in this way. Plants whose nature it is to run along

the ground, or up the trunks of trees, emitting roots as they proceed, do not have their stems buried near the ground. I apprehend that the explanation of this fatal result to trees is, that as the descending sap upon which the emission of roots so greatly depends circulates in the liber, its channel is destroyed, and, consequently, its downward course to the roots interrupted. The result is death to the tree, except in the case of such subjects as can form a new set of roots near the surface of the soil. Some plants can overcome these difficulties with less damage than others. However this position may be regarded, correct or incorrect in theory, the facts referred to remain the same.

In my experience of Vine planting I have found that in a certain degree, the results of which I have been speaking occur to the very letter whenever I have planted on the coil or laying system, and I have, therefore, abandoned it entirely. In 1859 I planted a vinery in the middle of June with Vines struck from eyes that same spring. A regular set of Vines was planted in an outside border, introducing them through holes in the front wall. Having plenty of Vines, I planted a few inside on the back wall of the house. The latter made two seasons' growth, and were fine strong canes in the autumn of 1860. The house is a narrow one, not more than 9 feet wide, and as I could derive little benefit from the Vines on the back wall I resolved, instead of cutting them out or training them down the roof, to try how the laying system would affect them. They were layed about 8 inches deep in the inside border across to the front, and shortened back to about 2½ feet above the surface of the soil. That season they had a regular struggle to reach the top of the house, and the growths they made were not half so strong as those made on the back wall in the first year of planting. At pruning time they were cut down again, and in 1862 they gave but a sorry account of themselves, though better than in the first season after being layed in the border. I had occasion to have to turn over the border in the winter of 1862, and found that these Vines had not made a root anywhere along their stems, except close to their necks—i.e., near the surface of the soil; at that point they had thickened and emitted a bunch of roots in a whorl all round the stem. From this instance I conclude that the action of the original root had been interfered with, and that until another set of roots could be produced and was in vigorous action, the growth of the Vines was most seriously interfered with. They were carefully layed, with no right-angle bends nor ruptures.

I will now give another instance somewhat differing from the foregoing. In 1860 I planted some young Hamburgh Vines in a new border. They were splendid young Vines, grown from eyes in the previous season, and planted in March. The vinery is arched in front, and has a 12-foot border inside. In planting some of these I layed them, putting their roots about 4 feet from the front wall into the inside border, thinking, perhaps, that this would induce them to root freely into the inside border, knowing how prone all Vine roots are to proceed through the arches into the outside border. Well, what next? These Vines stood

still for a long time after they had grown about 18 inches, and exhausted, as I suppose, the stored up sap. At length, after a considerable amount of patience had been exercised, they started into growth, and did pretty well. Two years afterwards on examining the inside border I found the original roots of these Vines absolutely rotten. The layed part of their stems had not thickened in the least, rather the reverse, and on following up these stems no roots were found till the place was reached where the Vine entered the border in front. The stems and old roots were cut away. I have planted a good many Vines in a variety of ways during some years, and could see nothing but mischief arising from laying the stems in the soil.

I will refer to another instance differing from the foregoing. In the course of renewing the Vines in a couple of vineries a few years ago, after planting there were some fine, strong, well-ripened Hamburghs for which I had no particular use, and so I determined to try the coiling system with them. In the new border inside the two vineries I plunged a row of these Vines, pots and all, in the soil. They were plunged so that the stems were buried in the border in a perpendicular position to the depth of a foot or 15 inches above the surface of the pot. Now these were splendid Vines, with buds like Nuts, and the object was to dwarf them a little, and prepare them for table. With this view a small pot was passed over each, so that it rested on the surface of the soil, and the Vines pushed up through the pots to the length of about 3 feet. These Vines broke strongly, showed magnificent bunches for pot Vines, but soon came to a stand-still, and never did any good. When they were removed it was found that the original roots in the pots had never made a move, and that an effort had been made to overcome their unnatural position by emitting roots near the surface. I had often forced Vines in pots before, and have since, but never without success, except when a portion of the stem was laid.

I could point to still another case adverse to laying Vines; Mscats which had been planted two years in one house were removed to another, and in planting them about 3 feet of their stems was layed. In the first year they made very little growth, and during the second their growth was not good, and the bunches all wired. The third year they fruited, but not satisfactorily. Improvement took place yearly, but they cannot now be said to have succeeded so well as they ought to have done. If examined now there is a thickened lump on the stems near the surface of the soil, and below that a mass of roots. The stems below or beyond that were layed in the soil, and have not thickened in the least since the day they were planted, and have only a small insignificant root here and there. Now I am perfectly well convinced that all these Vines would have done better had they not been layed, because all their cotemporaries not layed beat them completely. I have tried a good many ways of planting Vines. In one instance, for the satisfaction of my assistants, I planted a year-old Vine from a pot without in the least breaking-up the ball or uncoiling the roots. It was a strong Vine in an eight-inch pot. All the others in the same house, thirty-two in number, made magnificent growths; their roots were all uncoiled and washed. The Vine planted with the ball entire did not do nearly so well the first year, but it grew well in a few years, and made a good Vine. I prefer shaking out the roots entirely, and not burying a morsel of the stem.

Perhaps the experience of Mr. Rivers is quite opposite to mine as regards this coiling or laying system; but your readers will not be the worse of knowing that there are two sides to this as to every other question. What the consequences might be if the stem of a Vine were merely pegged down to the surface of the soil and not covered with mould I do not know, but I mean, if spared, to try the experiment. I rather think, however, that it is not the order of Nature with many plants to have many points for forming roots with advantage. The Vine, however, forms roots more freely than many plants or trees. The liber of the Vine is thin, and like many more subjects, it casts its coat yearly, and so exposes the channel for the downward sap more to the influence of the soil in which it is buried.—D. TROSBY.

MUSA VITTATA.

For the information of Mr. Sayers and "J. H." I may state that the above-named plant fruited for the first time in Europe about three years since in the Royal Botanic Gardens, Kew. Two years ago a smaller plant also fruited in the same gardens, but upon neither occasion was the produce eatable. That it

will become so under the management suggested by "J. H." remains to be proven; but I cannot endorse the statement made by him to the effect that out of every hundred Musas fruited in this country four only are good-flavoured.

By the way, is it not time "J. H." removed the veil in which he is shrouded? The statements we have read from him lately have made all the gardeners with whom I am acquainted exclaim, "Can these things be?"—Wm. HUGH GOWER, *Kew*.

Our young correspondent and his friends need not be incredulous of the statements made by "J. H." We know him to be a gentleman whose word may be depended upon. He has had large experience in the culture of tropical fruits, is now engaged in erecting houses for their extensive cultivation, and is well-known to some of our most distinguished Orchid cultivators. It pleases him not to proclaim his name and residence, and wisely for his own comfort does he thus avoid publicity, for as it is, we have had to forward to him many more letters than are desirable for an invalid to have to answer.—Eds.]

SOWING AND AFTER-MANAGEMENT

OF PELARGONIUM, VERBENA, AND OTHER CHOICE SEEDS.

(Continued from page 198.)

Encourage the young plants to grow as fast as they can, giving them at the same time all the air possible to cause them to become stocky, as well as to prevent their damping off. As soon as they have well filled their pots with roots and have made from seven to ten good leaves, they may be shifted into 48-sized pots. The soil for this potting should be stronger and not sifted so fine as recommended before; if it is rubbed through a riddle about three-quarters of an inch in the mesh it will be quite fine enough for them. Two-thirds of nice fibry loam, and one of leaf soil and sand should be used, and as much of it rubbed through the riddle as possible. The same care must be taken in crocking the pots as before, only so many crocks will not be required. I use about four pieces for a four-inch pot; placing the largest piece over the hole in the bottom of the pot, the others are then put in around it, and some of the clean fibre that could not be rubbed through the sieve is then placed on the crocks, just enough to prevent the soil from trickling down amongst the drainage. The stem of the plant should not be buried any deeper at this potting than it was before. The pots should be filled up lightly with the soil till about two-thirds full, then turn the plant carefully out of its pot, and after disentangling the roots from the drainage draw the soil into a little hillock in the centre of the pot. The plant should then be placed on the centre of the hillock, or cone, and the roots nicely spread out over its sides, a handful of the finest soil from the heap on the bench being then lightly sprinkled over them. After this has been done the pot may be filled up all round, then take it up with both hands, keeping both thumbs on the ball of the plant, one on each side of the stem, with the fingers clasping the sides of the pot, then tap the pot gently on the bench till the ball of the plant and the soil surrounding it have sunk down to about half an inch below the rim. It is of great importance to keep the thumb of each hand firmly fixed on the ball of the plant. This keeps it steady, and prevents its jumping about in the loose soil. If the operation of potting is carefully performed there need not be a single root broken, they will all be in their proper positions, and will at once begin working in the new soil.

None but those who have minutely watched the growth of a plant that has been potted with every care, and one that has been carelessly potted, would credit how great is the difference in their growth afterwards. This, then, is a part of the system of plant-growing that should be performed with great care, although some will say that where there are so many thousands of young plants to be potted it is a waste of time; but this is a great mistake, for if the operator will only take an interest in what he is doing he will perform his work well and quite as expeditiously as he who sticks his plants into their pots in any way, and fancies that he is very clever because he can pot a certain number of plants in an hour or a day. His hands may have been very busy, and at the end of an hour the bench may be nearly filled up with plants, but on running the eye over them one sees many of them very much out of the perpendicular, some are far from being in the centre of the pot, whilst in the case of others the soil has been pressed into hard uneven lumps above the level of the pots; and if you will take

the trouble to turn some of the plants out you will find vacant spaces in different places around the sides of the ball, and the roots broken and squeezed into every conceivable position. All this happens simply because the operator does not consider what he is doing, and his thoughts are concentrated on some other subject. It always pains me beyond measure to see some men take a plant in hand for the purpose of repotting it. For this reason I could on no account allow any one to handle my little pets. I have seen men potting plants in the fashion described above, and I have seen others in the same shed using every care in performing a similar operation, and I could always tell the difference in the growth of the plants afterwards, and could easily point out the plant potted by No. 1, or No. 2.

I have been particular in illustrating the different effects which the two systems of potting have on the growth of plants, for the purpose of more thoroughly impressing it on the minds of the many young gardeners, who may, if they will, benefit themselves greatly by applying these remarks to their practice.

The soil should be in a similar state as to moisture to that recommended for the last potting. It should also be about the same temperature as that in which the plants are growing. There will then be no necessity for watering the plants for several days after they have been newly potted. They should still be kept in a similar temperature to that recommended before, and for a few days after repotting them the house should be kept rather close. When it is found necessary to water them they should be well soaked; to do this effectually it will be necessary to go over them twice. After they have well established themselves in their new pots they should receive liberal treatment. The temperature may be increased as well as the supply of water, giving all the air possible on every favourable occasion. By this time the sun will begin to have greater power, the days will be longer, and the progress of the plants will be much greater in consequence.

We will now suppose ourselves to have kept our plants from harm, and with tender nursing and judicious care to have brought them through the dull months of December, January, February, and March. They will by this time have thoroughly filled their pots with roots, and will have matured from ten to twenty-five fully developed leaves. They should now be placed on a shelf, where they will have all the air that can possibly be given them, and the full benefit of the sun whenever it shines upon them. They must also be watered very sparingly from the beginning of April to the end of May, when they should be placed in the open air, and fully exposed to all weathers. During the two months they are undergoing the ripening process on the shelves, they should be frequently examined to see that they are not suffering any injury from want of water; and if any of them are growing too luxuriantly, I find it a good plan to push a sharp knife through the stem a little above the pot, making a slit upwards an inch or two in length; I then push in a small piece of charcoal or dry wood to keep the slit open. This checks their vigorous growth, and causes them to flower sooner.

If the directions given above have been properly attended to, by the middle or end of June many of the plants will be in bloom. They should then be supplied twice or thrice a-week with manure water given in a very clear state. It will soon be seen after a few weeks of this treatment how many of them are worth perpetuating. The best should be shaken out and potted into No. 16-sized pots, grown on under glass, and subjected to high cultivation. This will soon prove whether they are likely to be improvements on existing varieties by their freedom or shyness in flowering, the shape and colour of the flower, size of truss, &c. The most promising varieties are then propagated as rapidly as possible. Any that do not appear to be up to the required standard are thrown away. The second best are planted out when there is plenty of time, between the months of July and October, to prove them. Three or four cuttings of the best kinds are also struck as soon as possible, and planted out in trial-beds to prove their adaptability for bedding-purposes. Other cuttings of the same kinds are struck and grown on under glass to prove their capabilities in that way. Early in September most of the plants will have bloomed sufficiently to prove what they are likely to be either for pot culture or bedding-purposes. Then the stud-book is brought into requisition. This is often a very hard task, for there are sometimes a score or more of very promising flowers that one would like to keep till another year. It is, therefore, necessary to go over them again and again, to compare all the different features of each plant as to habit, neatness of foliage, freeness of flowering, shape of flower, size of truss, &c. When

satisfied as to the superiority of one variety over the others, a full description of it is written in the stud-book, and the work of propagating the favourite varieties goes on as rapidly as possible.

By carrying out the different operations as described in this and my previous article I am enabled to cross the flower, ripen the seed, raise the young plants, flower and prove them, all within the twelve months.

I should have stated that the varieties of Pelargoniums belonging to the Mrs. Pollock section require, during the various stages of their growth, to be treated rather differently from the more common bedding kinds. For instance, they will not stand the severe drying ordeal that the other varieties have to undergo during the months of April and May; they are also kept when in their young and delicate state at the coolest and driest end of the house, and about the middle of June are planted out on a piece of very rich ground.—J. WILLS.

(To be continued.)

WINTERING PLANTS FOR BEDDING-OUT.

THE preservation of flower-garden plants during winter is so important to every gardener, that it has been the subject of much reflection how best to accomplish it. It is of the utmost importance that the plants intended to be preserved should be secured before frost set in, and with this object in view they should be taken up from the beds with care, carried to the potting-shed, and, after having been carefully deprived of all their leaves, except those at the points of the branches, potted in soil well aired, and mixed with leaf mould rather dry than otherwise. I never use crocks for this potting, as I think that unnecessary. Water is never given for several days, unless the weather be very dry and warm; it does much harm to plants prepared for wintering. In fair weather give all the air possible by taking off the sashes, otherwise have them tilted at back, thus avoiding stagnant air and mouldiness, the results of bad ventilation. I have preserved plants from the end of October to March, without watering, in pits heated with hot-water pipes. People too often water plants when so doing is quite unnecessary; thus I have observed young gardeners after having potted newly-struck cuttings soaking them with water, and so ensuring the destruction of their plants. It would be much better to pot firmly, and avoid the water. As the potting of the store plants is at hand, I advise the young gardener to use water sparingly and pot firmly, which is much better practice than putting in loosely with the intention of making firm with water, as many do. Geraniums and other bedding plants may be kept in cold frames or pits, but water must be altogether withheld, and the foliage of Geraniums should be entirely removed. Calceolarias thus keep nicely. Cleanliness must be sedulously attended to in every department of plant-growing.—JAMES REID.

GAS-LIGHTED CONSERVATORY.

I SEE in your Journal of the 16th inst. a case of lighting a conservatory with gas. I have the management of a conservatory and stove, about 64 feet long, 23 feet wide, and 19 feet high, lighted by twenty-one gas-burners. I have had it lighted up at different times during the last two winters, and on the 20th inst. for four hours and a half, without any bad effects.

I generally water all the plants the first thing in the morning; give all the air I can to have the house properly dried before night; and before lighting I open the top ventilators, and leave them a little open while the gas is burning. Before putting it out I open them all at the top as wide as the weather will allow, and leave them open until the next morning.

I have not lost either a leaf or a flower from the use of the gas that I am aware of. There is a fine plant in a tub of *Sparmannia africana*, 9½ feet high by 5½ feet through, in splendid foliage and fine bloom, in the middle of the house. There are Azaleas, Camellias, Epacrises, Geraniums, Fuchsias, Primulas, and a general collection of plants, with some splendid *Acacias* upwards of 6 feet high.

I do not think gas will do any harm to the plants if the house is dry, and there is sufficient air on at the time.—A GARDENER.

YOUNG APPLES IN JANUARY.—I have forwarded you a sample of young Apples, gathered on the 16th instant. The tree was bearing its fruit last September, and these Apples are

the second crop. Have you seen any as large as these before this season? and what sort are they? They were growing in an orchard.

The Apples are as large as bantams' eggs. They may be Joannetings, but they are too immature for identification.

ROSES.

"Loch Ness," at page 22, speaks in the highest terms of "King's Acre." I do not think his experience of this flower will be borne out by many amateurs. I have only one plant of it, but it had several blooms on it last summer, and I saw a stand of blooms (I think there were two dozen or so), at the Crystal Palace Rose Show, and out of all these there was but one fit to put into a stand of first-class flowers. Moreover, I met at the same Rose Show a gentleman who is a very successful exhibitor, though he does not exhibit largely, and he told me that he considered this flower not worth propagating, and, in fact, although I had plenty of stocks I did not, after seeing the stand I have mentioned, think it worth while to add to my stock of plants by putting in any buds. I shall be very glad to find that I have been mistaken as to this Rose; but as to its ever superseding Jules Margottin, even if it were the same shade of colour, which it is not—why, when that happens Seigneur Vaisse must give way to Général Jacqueminot.

It is interesting to observe how differently some Roses do in different situations. "Loch Ness," I gather from his letter, finds Gloire de Santenay open well, and Duc de Rohan and Matrice Bernardin indifferently. Now, with me, the last always opens perfectly, whilst of the other two the Duc never opens well, and Gloire de Santenay is more often than not like a bullet.

General Washington, too, never yet opened well with me, and I had more than a dozen plants of it.

I think if "Loch Ness" is patient with Prince Camille de Rohan, and wait till his plants become strong, he will consider that flower Al. Its colour is superb, and the petals are wonderful in velvety appearance and substance. It might be a little fuller and larger; but such as it is, it is a splendid flower.—P.

ROYAL HORTICULTURAL SOCIETY.

JANUARY 23RD.

FLORAL COMMITTEE.—The first meeting in 1866 was held this day at South Kensington, and judging from the excellent collections of plants sent, we may safely conclude that the Tuesday meetings will continue to be well supported. There were not many plants sent for examination, and at this very early period of the year few could be expected. Mr. Bull sent three plants of *Pandanus ornatus*, an ornamental-foliaged plant with bright, glossy, dark green leaves edged with white spines. This will prove a very handsome decorative plant—first-class certificate; *Selaginella Mertensii* variegata, which was awarded a second-class certificate in 1865; *Herrania palmata*, a plant resembling a Palm, with handsome foliage—first-class certificate; and *Agave americana longifolia*. Mr. Bull also exhibited a large collection of stove and greenhouse plants, some of them of considerable merit in point of cultivation, and many of them rare; the Lindley medal, at the recommendation of the Committee, was awarded to Mr. Bull by the Council. It should be clearly understood that this medal is not intended as a prize for large collections of miscellaneous plants, but for specimens showing meritorious cultivation. See regulation No. 10, for the guidance of the Committees. "Medals will be awarded by the Council for subjects recommended by the Committee as evincing meritorious cultivation, but which are not exhibited as novelties." Mr. Earley, Digswell, sent a hybrid *Begonia* with deeply serrated foliage and pale pink flowers; and Messrs. A. Hanbury & Co., Pine-Apple Place, a fine specimen of *Lastrea Sieboldii* variegata, a decided acquisition among the variegated forms of Ferns in cultivation; a first-class certificate was awarded it. Mr. Veitch exhibited a magnificent collection of plants, forming quite a bank of splendid flowers. Among them were several Orchids—to one, a fine specimen of *Angraecum eburneum*, was awarded a special certificate. A similar award was made for the collection. Mr. Willcock, gardener to Dr. Pattison, sent a fine specimen of *Angraecum sesquipedale*, and *Barkeria Skinneri*, with deep rosy spikes of flowers. Mr. Williams, Holloway, sent *Calanthe speciosa nova*, but which was decided to be a form of *C. vestita*; also, *Angraecum eburneum*, and *Angraecum superbum virens*, both of which received special certificates. Mr. Reynolds, gardener to Dr. Sankey, sent a specimen of *Selaginella denticulata*, the points of the shoots being nearly white. It is doubtful whether this variegated form will prove constant. Several specimens were brought from the Society's gardens, among them *Odontoglossum hystrix*, and a very fine specimen of *Sophranitis grandiflora*, which was awarded a special certifi-

cate; also, a fine plant of the well-known *Pycnostachys urticifolia* with bright dark blue tufts of flowers.

FRUIT COMMITTEE.—G. F. Wilson, Esq., F.R.S., in the chair. But few subjects were brought forward on this occasion. A first-class certificate was awarded to Mr. R. H. Betteridge, of Milton Hill, Stevenage, for a seedling Pear, which was of excellent flavour. From Mr. Page, Southampton, came fruit of *Pyrus nepalensis*, resembling a Pear in appearance, but having a slight quince flavour, and though too hard for eating, possibly useful for preserving. The Chairman contributed some Ivedale's St. Germain Pears, grown in an orchard-house, and which, though not so large as those sometimes produced out of doors, were much more highly coloured. Mr. Tillery, gardener to the Duke of Portland, Welbeck, sent Trebbiano, Black St. Peter's, Muscat of Alexandria, and Welbeck Black Tripoli Grapes, in excellent condition. The last-named has been considered by some a distinct variety, but Dr. Hogg, in his "Fruit Manual," states it to be identical with the Frankenthal. From Mr. Culverwell, gardener to Mark Milbanke, Esq., Thorpe Perrow, near Bodale, came a bunch of Ferral Grape, unnamed; and from Mr. Sherratt, gardener to J. Bateman, Esq., Knypersley, a fine cluster of the fruit of *Musa Cavendishii*. A few Pears from the Society's Garden at Chiswick were also shown.

SCIENTIFIC MEETING.—Lord H. Gordon-Lennox, M.P., in the chair. The Rev. Joshua Dix having reported the awards of the Floral Committee to the meeting, Mr. Wilson, in performing a similar task with regard to the Fruit Committee, mentioned an electrical apparatus which he had seen at Professor Wheatstone's, which being set at any two temperatures—say 40° and 70°, would ring a bell at the gardener's bedside, if the temperature of any house in which the apparatus was placed fell below the one limit or exceeded the other.

The Rev. M. J. Berkeley in reviewing the subjects exhibited, remarked that a new *Calanthe* exhibited by Mr. Williams, only differed from *Calanthe vestita* in the centre of the flower being marked with rose colour instead of yellow as in that species, and to which he had no doubt it belonged. An *Odontoglossum* sent home by Mr. Weir, and shown at the last meeting, was stated to be *O. hystrix*. Mr. Berkeley then directed attention to one of the Aroidæ in Mr. Bull's collection, *Nantheosoma appendiculata*, in which there is a curious process formed by the upper portion of the midrib being reverted, and forming as it were a second leaf at the back of the first, but facing in a contrary direction, and he observed that he had seen a similar peculiarity of structure in a Fig which had been sent home from India. Of *Draecena fragrans*, a plant of which came from the Society's garden, it was remarked that though not very attractive it was very fragrant at night, having the odour of new hay; and of *Ficus Cooperi*, that it was a native either of tropical Australia or the warmer parts of Natal. *Palicourea discolor*, belonging to the natural order of Cinchonaceæ, and *Pycnostachys urticifolia*, closely allied to the well-known Colens, were next adverted to, and the latter, though of a rather straggling habit, was stated to be worthy of some consideration on account of its fine blue heads of flowers. *Herrania palmata*, exhibited by Mr. Bull, and belonging to the natural order of Byttneriaceæ, was closely allied to the *Theobroma*, from the seeds of which chocolate is made; and in connection with *Pyrus nepalensis*, Mr. Berkeley remarked that notwithstanding the distinctions drawn between *Pyrus* and *Cydonia*, those botanists are right who unite the two. He next directed attention to one of the fine fruiting *Ancubas* from Mr. Bull, remarking that such a plant was worth from fifteen to twenty guineas, though a similar one not in fruit might be purchased for about half-a-crown, and that a small example of the male plant was now worth two guineas. The pretty variegated *Selaginella Mertensii* variegata was also alluded to in terms of commendation.

The Chairman said his next duty was to introduce Mr. Hungerford Pollen to the meeting, who would state his views on the arrangement of floral displays, a subject which had excited a considerable amount of discussion of late.

Mr. H. Pollen began by observing, that the best mode of arranging plants and fruit at exhibitions was a subject of considerable interest, and he quoted the views advanced by Professor Reichenbach and Dr. Masters on the subject. Here the materials of such exhibitions were mostly arranged together, but on the Continent they were grouped so as to produce the best pictorial effect, though this system might not always be so well for displaying the properties of the plants; yet he thought it perfectly possible to unite both objects. Professor Reichenbach had spoken of the great difficulties of finding and comparing plants arranged on the continental system, but without going so far as that, each exhibitor's productions might be so placed as to produce an artistic effect. In order to see how plants and flowers look best we ought to go to Nature, and what struck one most there was the enormous amount of light which was present. The consideration which followed was, how plants were situated in regard to that element in arcades, buildings, and tents; in the first two the light was almost invariably from one side, but in a tent it was diffused all round, and that in the most agreeable manner; hence, he considered that the tent carried the day for the exhibition of plants. In art, as in the case of statues and paintings, it was an object to concentrate all the light on a certain point, and the rest of the object was, therefore, left more or less in the shade; but to do justice to flowers they should have a very large amount of light. In buildings, however, as already stated, this was not the case, for the light coming from one side the greater part of

the plant was left in the dark, and many of its beauties were consequently hidden. If he were asked how best to secure the greatest amount of light, he would answer, in a tent. As an example of the fine effect produced by the intermixture of flowers and foliage in tents, he cited the Rhododendron Show held last year in the tent erected by the late Capt. Fowke, R.E., a tent of which the like had never been constructed in this or any other country. There, instead of all the flowers being put together and all the foliage, the two were mixed, and to the best advantage. When a large number of flowers were collected together without a proper amount of foliage, the eye could not see their separate forms to the best advantage, and could not take in the overpowering amount of colour so produced. Flowers, therefore, should be mixed with foliage; and in the case of plants growing naturally there was grass and a beautiful irregularity of surface. The chief points to be kept in view in arranging plants, said Mr. Pollen, are—1st, light; 2nd, background; 3rd, surface. With regard to the third point, some plants are better when below the eye, others when above it, but for the purposes of a judge the nearer the eye they are brought the better. Mr. Pollen then stated, that he had seen on the Continent, but never in England, long or square boxes of grass made available for setting plants on, and he recommended exhibitors to have such boxes prepared beforehand, by turfing or sowing, so as to be ready for use in any way that might be necessary when the plants came to be set up. White paper might also be usefully employed more frequently than it is in exhibitions. In the flower markets it was always used with the finest bouquets, and all the finest prints were mounted on it. Mr. Pollen then described an ornament which he had seen when in the Apennines, where, on entering a monastery and in vain looking for any one for a long while, he came on a monk tracing out on the pavement a design in chalk, which was afterwards filled up with Box, and Poppies, and other wild flowers. This, Mr. Pollen said, was the most beautiful thing in its way that he had ever seen. Other means of decoration not made use of so often as they might be, were gravels, sands, and other coloured materials—such as might be seen in Mr. Nesfield's patterns, and which were especially useful when flowers could not be had. By such means most pleasing results might be obtained. One other point to which he would advert, was the best mode of showing fruit; and he could not help thinking that, as in the case of flowers, the best way of doing so was on the boxes of grass as if the fruit had fallen on them, or on very white china. Moss was sometimes used, but unless very green it had not a good effect. Mr. Pollen said in conclusion, that his remarks were merely made with the view of provoking discussion, and drawing forth some hints on the best mode of showing flowers and fruit. If all the world were judges the present mode of doing so was the best, but a vast number came to exhibitions to learn how to improve their gardens, and on that account it was necessary to introduce as much art as possible into the arrangement of the subjects shown.

The Chairman, after thanking Mr. Pollen for his remarks, said he should be glad to hear any gentleman inclined to offer observations on the subject.

The Rev. Dr. Rock fully coincided with the observations made by Mr. Pollen, and remarked in connection with what Mr. Pollen had seen in the Apennines, that he had himself seen a road near Rome covered with flowers; and as an illustration of a somewhat similar style of decoration, mentioned the festival among the hills of Derbyshire, known as the well-dressing of Tissington. Such customs had a civilising tendency in our villages, by implanting a love of flowers and bringing the villagers in contact with the neighbouring gentry.

Mr. W. Wilson Saunders said the question was, What are exhibitions instituted for? If they were only intended to please the eye then the artistic mode of arrangement would be very well; but there was another object to be kept in view—that the subjects exhibited should be so placed that the judges could decide on their comparative merits. He thought that the present high state of horticulture in this country was in some degree to be attributed to the fact, that our exhibitions were exhibitions of merit and not of art. He fully concurred with Professor Reichenbach as to the difficulties which judges have to undergo when the subjects of exhibition are scattered here and there for the sake of artistic arrangement, and whilst he hoped that horticultural exhibitions would be made attractive to the eye, the main object should be to render them as instructive as possible.

JANUARY 27TH.

At the Exhibition held this day, there was a pretty display of greenhouse plants exhibited by William Bartlett, Esq., Shaftesbury Terrace, Hammersmith, which contained two fine large specimens of *Adiantum cuneatum*, a nice specimen of *Adiantum capillus-Veneris*, and various other Ferns and fine-foliated plants, interspersed with well-grown Hyacinths, Tulips, and Polyanthus Narcissus in bloom. This received a first prize.

In the Fruit department, Mr. William Earley, gardener to Felix Pryor, Esq., of Welwyn, exhibited a collection of Apples which had the merit of being well grown and well kept. They consisted of some of the finest dessert kinds, such as Cox's Orange Pippin, Ribston Pippin, Golden Pippin, Cocker Pippin, &c., consisting in all of eighteen dishes; and for this he was awarded a first prize. He also exhibited a dish of well-preserved Walnuts, which were quite fresh; some excellent Salsify, which received a first-class certificate; and a dish of Shallots, which also received a first-class certificate.

It appears to us that these Saturday meetings open-up a field which has never yet been occupied, and offer advantages which a certain class of exhibitors would be too glad to avail themselves of, provided they were aware of the opportunities they offer. At these meetings amateurs, and those who have small space at command for indulging their horticultural tastes, can meet on equal terms and contest their skill one with the other without the fear of being overwhelmed by the greater and more professional exhibitors. We have often felt that the amateur whose circumstances or convenience prevents him from taking part in the great shows, has no opportunity afforded him for exhibiting his skill in the art in which he takes so much delight, and which he cultivates so well; but from what we saw of Mr. Bartlett's exhibition on Saturday, we look forward with pleasure to the day when Mr. Bartlett will have to compete as well as exhibit. There are many in town and in the suburbs who have no other convenience than a small conservatory, and many who, failing such a structure, improve any sort of arrangement so that they may indulge their favourite pursuit, who could on these Saturday Shows bring out their two, or three, or half a dozen well-grown plants, and exhibit their skill while they contest the honour with their neighbours.

THE IRESINE HERBSTII.

Your correspondent, Mr. Hill, has not said one word too much in praise of this useful plant. It has exceeded my expectations both for bedding and as a decorative plant in the autumn and winter months in the houses and at the mansion.

Where groups of plants in the ribbon style are wanted in corridors and saloons, the *Iresine* is indispensable, and it makes an excellent second row if Golden Chain Geranium is used for the border. Both the former and the latter are more suitable for such a purpose if grown in propagating-pans about 12 inches by 8, and 4 or 5 inches deep, as the foliage will nearly cover the sides of the pans. *Chrysanthemums*, *Dracanas*, *Poinsettias*, *Cyperus alternifolius variegatus*, and Ferns, are the most effective for the centres or backgrounds of such groups. A very small and neatly-arranged wreath of evergreens is necessary to lay down just under the leaves of the Geraniums; this will hide any part of the pans which may be visible, and also enhance the gold colour of the leaves.

There is another purpose for which the *Iresine* may be used with very good effect—viz., for decorating the dessert. I have not seen it recommended for that purpose, and wonder Mr. Robson did not mention it in his excellent article lately on table decoration, as few plants worthy of notice escape his mind. Small bushy plants, or say several cuttings, placed in round flat tins to be grown on and placed in flat vases, are very ornamental when placed amongst the dessert. Ferns and many other plants give us plenty of green, but high-coloured leaves are necessary to finish the picture.

A long shelfful of *Iresine* in a stove in the winter months, is one of the most attractive ornaments in that structure. In the greenhouse it sheds its leaves, and a cold pit is death to it. Few plants are more easy to propagate and cultivate, and I feel assured that it will be one of the most useful ornamental-foliaged plants we shall have for some years.—JOHN PERKINS, *Suffolk, January 17th.*

NOTES ON GRAPES.

Mr. HILL, of Keele Hall, has sent us a collection of Grapes, the following notes on which will doubtless prove interesting to many of our readers, who will appreciate information coming from a source so reliable, and from one who has devoted so much attention to the study and cultivation of the Vine. Mr. Hill has for many years been making experiments, not only on the merits of different sorts of Grapes, with the view of ascertaining to what extent they are worthy of cultivation in our vinerias; but he has devoted a great deal of attention to what is a subject of even greater interest—the influence of various stocks on these varieties. We have in the following notes the result of Mr. Hill's experiments during the past season:—

No. 1.—*Lady Downe's grafted on the Black Eagle.* The Black Eagle is a weakly-growing Vine, having no merit of its own to recommend it, and yet the bunch of Lady Downe's sent by Mr. Hill is of full size, and of a fine deep black colour; but the berries are not so large as in the following. The flavour is excellent, and there is the slightest trace of Muscat in it.

No. 2.—*Lady Downe's grafted on Gromier du Cantal.* The stock on which this was produced is a strong grower, and the size of its own bunches is generally large. It seems to have communicated some of its vigour to the scion, for the bunch of

Lady Downe's produced by it is of very large size, and the berries are unusually so, jet black, and highly flavoured. Altogether superior to the same variety on its own roots.

No. 3.—*Lady Downe's grafted on the Black Hamburgh.* The berries are large and well coloured, and the flavour excellent.

No. 4.—*Lady Downe's grown on its own roots.* Although the bunch and berries are not so large in this case as in that where it is grown on *Grolier du Cantal* and *Black Hamburgh*, the flavour seems richer and more sugary.

No. 5.—*Lady Downe's grafted on Chasselas Napoleon.* The bunches and berries are small, and very inferior in every respect to all the preceding.

No. 6.—*West's St. Peter's grafted on Barbarossa* (Gros Guillaume). The flavour here is more than ordinarily rich and sweet, and there seems to be more sugar than is usually present. The berries, however, are not so large as in the following:—

No. 7.—*West's St. Peter's grafted on Muscat of Alexandria.* The stock has evidently exercised an influence here for the better, the berries being more than ordinarily large, and the flavour rich. We almost fancy we can detect a slight indication of the Muscat flavour occasionally.

No. 8.—*Black Alicante* (Meredith's). This is the true Alicante of Speckly, and a very different Grape from that which appeared within the last few years as *Kempsey Alicante*, which proves to be the Morocco. The flavour is very delicious, and it is one of the best late Grapes.

No. 9.—*Cox's Black Alicante.* This is the Grape that gave rise to the name of *Kempsey Alicante*, but which is the same as Morocco.

No. 10.—*Gros Maroc.* This is a large olive-shaped Grape, as large as Morocco, but colours much better. The flesh is tender and melting as that of the *Black Hamburgh*.

No. 11.—*Black Eagle.* This is a small black Grape, both in the bunch and the berry, and does not appear to possess any merit.

No. 12.—*Golden Lady Downe's.* This, a white form of the *Black Lady Downe's*, and exactly similar to it. It produces the same cylindrical form of bunch, the same large round berries, but with a fine golden yellow colour, and the same firm crackling flesh. It is now (January 27th) as plump, firm, and as juicy as it might have been in October, while all the others we have mentioned are more or less shrivelled.

No. 13.—*Child of Hale* is an oval Syrian-looking Grape, but does not possess any striking merit.

GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 11.

THE railway journey from Bologna to Milan is through a rich pastoral country with low-lying fields of rice or grain and dykes bordered with *Myosotis palustris*, with here and there large patches of a brilliant blue *Teucrium* (*regium*?). I felt very jealous of this particular railway journey, remembering our pleasant drive, in days gone by, through Modena, Parma—sacred to Correggio and his frescoes—Piacenza, and Lodi, where the women wear a long black Moorish veil, which is exceedingly becoming, and where, in fields knee deep in pasture, it is said that eighty thousand cows are kept to supply milk for the Parmesan, Gruyère, and other cheese.

It was very tantalising to pass rushing onwards, catching only glimpses of the wild flowers one longed to possess; but, after awhile, the earth, with its many-coloured carpet, was forgotten in the entrancing view of the snow-capped Alps, which broke upon us out of cloudland, revealing itself not in one full burst of beauty, but in dream-like visions that made you thirst for nearer, closer revelations. Is there anything that can be compared with snow mountains?—any feeling like that which is awakened by "Is it a mountain or a cloud? Oh, how lovely! What is it—so radiant in its glowing purity—now appearing, and now gone, as if a door were suddenly opened and shut, through whose portal you saw distant glimmerings of light and beauty which only flashed across your dazzled sight to vanish away." As evening came stealing on, the parting clouds showed the same wonderful images changed to a rosy light. The most refrulgent glowing rose colour rested on the mountain snow.

From these visions of the work of God we passed to that most perfect work of man—the Cathedral of Milan, built of the purest white marble, its thousand en-cased minarets gleaming against the sky. We sat down in the broad Piazza watching it, as the stars one by one appeared twinkling in the heavens

above, and the round clear face of the moon appeared over the tower, adding her mysterious light and shadow to the scene. In the dim light we observed a crowd of people passing into a little church near at hand—we, too, entered. The church and the numerous congregation were in deep shadow, save at the altar, where a brilliant blaze surrounded what is called the "Exposition of the Blessed Sacrament," and revealed the kneeling priest before the altar. Around us on every side rose voices in a loud murmur of petition; the priest's sonorous voice saying a litany, in the responses of which the kneeling people joined. It was a strange scene on that work-a-day evening—poor and rich kneeling side by side together in one common supplication.

The interior of Milan Cathedral, though full of beautiful details, is, to me, disappointing, and the roof is painted in imitation of stone!—but the glory of the interior consists in the shrine of St. Carlo Borromeo—the modern saint, whose virtues seem to have eclipsed those of Milan's anciently revered St. Ambrose. But St. Carlo's virtues, unlike those of many of the latter-day saints, will bear a scrutinising gaze. In 1505 we see him presiding at the Provincial Council of Milan in which canons were enacted, protesting against some of the abuses of the Roman Church. Afterwards we find him "selling all his goods to feed the poor;" and, when the dreadful plague visited Milan, he was the first in every office of love, personally rendered to the sick and dying; so I did not begrudge St. Carlo his gorgeous shrine, albeit the gold and jewels poured out upon and all around it with such lavish prodigality seemed a little out of place for one whose motto in life and death was "*Humilitas*."

Everything in Milan has a clean and characteristic square look about it that I have noticed in no other foreign town. There is more air, more sky, and, I fancy, more soap and water.

The public gardens are very fine, and on Sunday afternoon we found a band playing, and crowds of gaily dressed folk enjoying the music as far as a continuous flow of chatter would allow them, as they walked up and down broad avenues of Chestnuts in full bloom. In these gardens I noticed beds full of *Deutzia gracilis*, the bloom hanging like wreaths of snow upon them. I had but one fault to find with the gardens, and that was that they were too well kept to allow of my gathering any wild flowers; but, indeed, the dear old untidy freedom of Italy seems vanishing away beneath Victor Emmanuel's sway, so that I had to look on a world of sulphur Roses hanging in festoons from the trees, on boughs of *Cercis siliquastrum*, and the *Petunia* Tree hanging temptingly close to my hands, without venturing to gather a blossom; and yet I must own that I have never seen public gardens that struck me as being so well kept, so handsome, or so appropriate to the purpose for which they are designed; and the numberless happy parties we found at every turn proved that they were appreciated.

One of the most ancient churches in Milan is that of St. Lorenzo, before which there stands a row of columns as ancient-looking as those before the Pantheon in Rome, while within the church there are mosaics corresponding in style, and I believe in date, with those in the churches of St. Constanza and St. Prassede at Rome.

The picture gallery of Milan is not so full of gems as that of Bologna. There is the *Spesalizio* of Raphael, one of his early pictures when in Perugino's school; Abraham's Dismissal of Hagar by Guercino, the chief beauty of which lies in its colouring. There are also some grand pictures of Paul Veronese, but nothing that leaves any very lasting impression of beauty. We found the celebrated *Concetta* of Leonardo da Vinci in the refectory of St. Maria delle Grazie much the worse for the wear and tear of the ten years that had passed since we had seen it; the photographs of the original are really useless to convey any idea of the extreme beauty of even what is left of this painting, but there is a "touched-up" photograph which is very good. The head of the *Redemer* is still beautiful, the original sketch for it is preserved in the Bra, and is well worth a study from its portraiture of grief, unearthly in its intensity of sorrow. It depicts the moment in our Lord's life, with which, perhaps, from its humanity we can best sympathise. The friend in whom He trusted, for whom He is bearing so much, is about to betray Him. Leonardo has blended this human grief and Divine love in most wondrous harmony.

Still on by rail to Susa, a little village in the bosom of lofty mountains, where beggars, tidily clad and well-to-do-looking, meet you at every turn, some of them with many rings on the fingers held out for charity, and gilt ornaments on their

throats—a curious primitive mountain race, regarding the railway much as we regard a new comet, wondering whether its advent portends good or evil, but in either case whenever it is visible, always gazing and always wondering.

Susa is a first-rate place for botanical scrambles, so directly after we arrived we set off in search of plants. First my companion found, in the crevice of a huge rock, several fine plants of *Asplenium fontanum*, fresh and green—my companion, mark, who thought it was viride, and not I, who knew better!—so unequally distributed are Fortune's favours. Oh! how jealous I was, and am to this minute, for I could find no other root, though I searched long and well. I longed to see this delicate and lovely Fern in a home of its own choosing. I remembered my long and unavailing struggles to make it take kindly to English soil, how the slugs would eat the young juicy fronds, and the sun would dry them prematurely, so that at best some half-dozen slug-eaten, dark greenish-yellow fronds were all I ever could manage to show in my Devonshire fernery. I hardly wondered when I looked at *fontanum's* own dwelling-place—the cozy, shady crevice in the warm sun-beaten rock, the pure mountain air bringing moisture from the snow-laden Alps on its journey to the south. I must certainly go again to Susa that my friend may no longer feel she outshone me in that Fern scramble!

On another mountain I found quantities of the *Anemone alpina*—a true Wind-Flower, for, after a few days' ripening in the sun, the feathery petals fly off at a touch, like the seed of the Dandelion, by which, in our childhood, we used to count the hour, calling them "clocks." The leaves of the *A. alpina* are of the softest, most silvery-looking green. I tried to dry the flowers, but at the least pressure the whole fabric gave way, leaving only a heap of fluffy ruins; but I have since seen these gummed together in a mass, which preserves the appearance of the original flower. The specimen I refer to came from the Pic de Bergons in the Pyrenees.

In the same neighbourhood we found *Silene italica*, which has the most delicious scent. Some of the meadows were literally covered with the *Narcissus* poeticians: we gathered handfuls, and I fear their extreme beauty and scent rather diverted us from the more rare specimens which seemed to abound on every side. Growing amidst the *Narcissus* was a tall and very handsome *Scorzonera (villosa?)* with large amber flowers, the solitary leaves completely clasping the stem: at first I thought it *Hieracium amplexicaule*, but I afterwards found the same plant in the Botanical Gardens at Geneva with the name I have given. I also found a large and very handsome yellow Vetch. *Berberis vulgaris* grew in quantities on the rocks, and many another shrub and flower, gone, alas! from my memory and my book. In the latter are still many specimens unnamed, indeed one whole page full, for on my return from our hunt I found a large collection of plants just brought in for me by two of our railway companions—English gentlemen, who, seeing my taste, kindly set off on a flower-hunting expedition to gratify it, and, in addition to Susa specimens, added *Daphne cneorum* from Lago Maggiore where it abounds in profusion, and other Italian finds.

What a pleasant evening we had in that queer old rickety Italian inn, discussing our numerous treasures over a cup of English! tea, made from a private store, carried by us for specially honoured occasions—a party of entire strangers, yet how unstranger-like meeting so sociably together on that evening, yet never to meet on earth again, for the strangers were to be up with the light and away over Mont Cenis in a diligence drawn by fourteen mules, while we were lazily turning round in bed meditating on the pleasures of *vetturino*, or devouring fried little birds, with other mountain delicacies, at breakfast. It seems a great mistake for the pass of Mont Cenis to be made in the night time, which is, however, the most popular time for the diligences; looking back to our ascent I feel I would not have lost one half hour of daylight for the world.—
FELIX-FEMINA.

GOLDEN AND TRICOLOR-LEAVED GERANIUMS.

If the importance of the advice given by Mr. Reid at page 26—viz., to have the plants well established in pots before planting, were more fully recognised and carried out, we should have fewer complaints about the "shabby appearance," and "the difficulty of management" of these valuable Geraniums. On the plants being small and sickly, or strong, healthy, and well established at the time of planting-out, depends failure or success. Few need ever think of being successful with these

Geraniums by submitting them to the treatment generally accorded to stronger-growing varieties. They require much more coaxing and nursing throughout the winter and spring months, to have them in perfection in summer.

Having been here very successful in the propagation and after-management of some kinds of the above Geraniums, I venture to state how we proceed with them. The plants, being lifted from the flower-beds in autumn before they experience any frost, are potted in light, rich soil, and placed near the glass in a house where the temperature can be maintained at about 50°. They grow away strongly, and by the 1st of February are capable of producing a large number of cuttings. These are taken off when about 2 or 3 inches long, and only the very undermost leaves are removed. The more leaves left on the cuttings the sooner will a callus be formed, and rooting take place. The soil, composed of about equal parts of leaf mould, decayed sphagnum, and silver sand, being prepared, small (54-sized) pots are filled with it. A hole is made in the centre of the soil in each pot, and filled with silver sand; the cuttings are then inserted in the sand, and after having been gently watered, are plunged near the glass in a bottom heat of 75°. They are placed thinly together, so that each leaf may catch all the light possible, a most important point in the short days of early spring. They receive no more water except a skiff or two with the syringe every day until rooted, which they are to the sides of the pots in ten or twelve days. They are then potted into 3½ or 4-inch pots in a soil similar to that used at first, with the addition of a little loam, and decayed cow or sheep-dung. It is here that the advantage of having each in a small pot is made manifest. They can be potted without destroying a single root, whereas, if lifted or shaken out of pots or pans, the roots are more or less mutilated, consequently the plants receive a severe check, which materially affects their growth. After being potted they are again placed near the glass in a warm house, and being regularly attended to in watering, they grow vigorously, soon filling their pots with roots. About the middle of April they are placed in a cold pit or frame, and in about three weeks more are placed out of doors where they can be protected on the appearance of frost. Towards the end of May they are turned out of their pots and planted in their summer quarters. A too sudden transition from a high to a low temperature must be guarded against, for if the plants be subjected to this the loss of a large number of the under leaves will be the penalty. Although it involves a little more labour, it is far better to harden-off gradually, in which case no bad results follow.

Here, out of several hundreds, including Mrs. Pollock, Sunset, and others, propagated and treated in the manner described, not a single cutting or plant was lost; and when planted out they grew so vigorously as to more than realise the most sanguine expectations formed of them.

It is only for those who have had any difficulty in managing these excellent and showy varieties of Geraniums that I have ventured to make these remarks. Through a deficient knowledge of their special requirements, many plants have eventually suffered martyrdom at the hands of their best and warmest friends.—J. A., *Whittingham Gardens*.

THE OLD FIG TREES AT ST. JOHN'S, NEAR RYDE.

CLOSE to the east side of Ryde, in the Isle of Wight, stands the old manorial residence of St. John's, long the family seat of the ancestors of Sir John Simeon, Bart., M.P. The Simeon family have not lived there for upwards of thirty years, but reside at another seat towards the west end of the island. During the above period the house has always been let to some family of distinction. Since the Simeon family resided here the town of Ryde has more than doubled in extent and inhabitants, and is every season attracting a larger number of the middle and upper classes of society, who are able to afford and can enjoy a short stay at the seaside. Few towns possess greater attractions than Ryde, and being readily accessible from London and every large town, none need hesitate to take a journey to Ryde. There are four lines of railway that come to some convenient landing place on the opposite shores. Portsmouth and Stokes Bay are those to which passengers come who wish to reach Ryde by the nearest route. Then for passengers from the west, there are Southampton and Lymington.

But to return to Ryde and its visitors, and the old gardens at St. John's. About fourteen months ago there died in the

cottage, which is in the kitchen garden, Mr. Lawrence, the gardener. Mr. Lawrence had been there more than forty-four years, he having been in the employ of the Simeon family for a number of years during the late Sir Richard Simeon's life, forty years ago. None of the new-fashioned notions about flower gardening were then dreamed of—this Mr. Lawrence has often told me; and then after the family gave up living there, the object most kept in view was how to make the most of the kitchen gardens, or I might with greater propriety call them fruit gardens. They were three acres in extent; two acres were enclosed by high brick walls. These had originally been very substantially built; but for many years past time has been showing its effects on them, and here and there they have required buttresses to keep them up. The climate being mild, Fig trees always formed a noticeable feature, and were so when my old friend, Mr. Lawrence, became gardener forty-five years ago.

I have already remarked that after Mr. Lawrence had been at St. John's about ten years the family went to live at Swanton, in the west of the island, and that the house was let, but

the gardens were not, and Mr. Lawrence sold to the tenants of the house whatever they required from the gardens, and then disposed of the surplus produce as best he could. For the first few years he sold fruit to the shop-keepers at Ryde; but as the town grew and became more fashionable the fruit garden at St. John's became better known, and ultimately he had no need to take any of his fruit to Ryde.

I may take it for granted that every person, young as well as old, is familiar with the dried Figs of the shops, and which are chiefly imported from the shores of the Mediterranean; but, probably, not nine out of a hundred of those who eat them have ever enjoyed the rich and refreshing treat of half a dozen genuine ripe Figs fresh gathered from the tree. There could be no comparison between the fruit gathered, perhaps before properly ripe, squeezed into the least possible compass in a box, and carried some hundred miles by sea, and the many thousands of ripe Figs which Mr. Lawrence gathered every year for more than a generation. Many are the visitors to Ryde during the summer, and the Ryde season is generally the gayest during the time out-door Figs are in, and if ever a gardener

Fig. 1

felt a pleasure in his employment it was my old friend in everything respecting his Figs and Fig trees.

There are about twenty-six or twenty-eight of them, and one-half of them are growing over a wooden trellis, which quite covers a walk running across one of the compartments of the garden; the others are growing on the outside and inside of one of the outer walls of the garden. For years Mr. Lawrence had carefully cut, pruned, and regularly tied in those Fig trees which are against the walls; but, being a quick observer of everything which came under his care, he perceived that those trees (and, perhaps, no equal number in any part of England can be compared with them), which were not so treated, but were left more to themselves, bore a far greater number of fruits, and were, moreover, shorter-jointed, and did not make so much gross wood as the trees against the walls, with which he took such great pains. He, therefore, gave up pruning them, and for years before I became acquainted with them they had assumed quite the character of trees, and during summer, while in full leaf, they quite hid the garden wall, on one side extending to from 4 to 6 yards from the wall, and reaching over it for 1 or 2 yards. These Fig trees had for a generation never been

pruned in the ordinary acceptance of the term, but when they became over-thick Mr. Lawrence, saw in hand, cut out the branches to the required distance apart.

The Fig trees had long been well known to a large portion of the visitors to Ryde; but the town has of late years grown so fast that it is now almost close to St. John's, and last autumn the old garden and all the adjoining land were bought for building-purposes. I am therefore afraid that these old, noble, and very productive Fig trees will now soon be numbered with the things which have been. I have often wished that some photographer would take them, the picture they would make would be interesting, independently of its furnishing a faithful record of what they have been. Their produce always commanded a high price when Ryde was full of company, and should they be destroyed will be much missed. Every year, when we had no cold and chilly night about the end of April, May, or the beginning of June, ripe Figs might be expected by the thousand in August and September, and up to the beginning of October if the weather was fine.

Passing through St. John's garden soon after it was sold for building, and thinking over the changes which in all probability

would soon cause these Fig trees to be reckoned as things of the past, and how short a time ago it was that my old friend was busy amongst them, by way of securing a memorial of this old garden and its Fig trees, and associating them with the memory of Mr. Lawrence, whose genial flow of spirits and general information were always very refreshing to every one who called in to see him, I pencilled down some resemblance of the stems of a few of the largest trees, and I think the sketches may prove of some interest to the readers of THE JOURNAL OF HORTICULTURE.

One part of the garden is divided into four equal quarters by walks crossing at right angles in the middle, and one of these walks is quite covered with Fig trees. The walk to the north

enters right into the back-sheds and fruit-rooms. At 6 or 8 feet to the right is an old vinery; and between the fruit-room door and this vinery is a Fig tree, which had originally been trained to the garden wall and over the top of the doorway. Fig. 1 represents the lower portions of this Fig tree, and how it passes over the door. As I have already mentioned, none of these trees have been pruned for more than thirty years, only thinned-out when the branches became over-crowded. The separate stems shown in fig. 1 measure just above where they unite that on the right, *a*, upwards of 3 feet in circumference; that in the middle, *b*, nearly 3 feet 4 inches; and *c*, upwards of 2 feet 6 inches. One branch is entirely resting upon the trellis over the walk.

Fig. 2.

At the upper corner, outside the garden wall, is the largest-stemmed tree (fig. 2), and as a standard the most perfect amongst them. In all probability it had at one time been very much under knife treatment, and probably its branches were tied to the wall; however, it will be at once seen from its very robust appearance that it has not been in fetters for many years. The trunk, *a*, before dividing measures in circumference 4 feet 6 inches; the branch, *b*, 2 feet 2 inches; *c*, 1 foot 9 inches; *d*, upwards of 2 feet.

I observed just before entering the garden that one of the

best and widest-spreading of the Fig trees was all but cut away. It had quite a dome-shaped appearance, the branches extending 28 feet in diameter, and 20 feet in height. Birds are very fond of ripe Figs, and whenever nearly ripe the trees must either be netted over or each separate fruit bagged. I have often thought that these Fig trees would well repay the expense of covering them with glass, thus securing them from the cold chilly nights of spring as well as from birds. Mr. Lawrence repeatedly told me that he had gathered a bushel or two of ripe Figs in one day.—G. DAWSON.

WORK FOR THE WEEK.

KITCHEN GARDEN.

JANUARY has proved a seasonable month, with just enough of frost and snow to check vegetation; had we experienced the severe cold that sometimes takes place after a mild November and December, the effects would have been very serious. We must not, however, be dejected into indifference respecting February, and withdraw protection from tender plants in matted beds and frames, or from vegetables where a regular supply is required. Whilst the frosty weather continues wheeling manure, composts, &c., ought to go on uninterruptedly till finished, in order to save the walks in the spring. As the frost has not as yet penetrated deep, digging and trenching all spare ground for spring crops must be proceeded with. The ground for Onions ought to be left very rough for the frost to pulverise it. It is a crop to which great attention ought to be paid, being in general demand. *Cabbages*, fill up vacancies in the autumn plantation, also make fresh plantations of the autumn sowing if necessary. *Cauliflowers*, those under hand-glasses and in frames must be fully exposed in mild weather, or they will button-off in the spring. Sow seed on a south border to produce plants to succeed the autumn sowing. *Chery*, sow seed in boxes, and place them in a forcing-house to produce plants for an early crop. *Cucumbers*, as soon as the plants are turned out, thrust a stick under each hill, and examine it frequently; if there is any approach to a burning heat draw as much of the soil from the bottom of the hills next the turf as you can without disturbing the plants, afterwards give the centre of the bed a good watering, which will act as a temporary preventive of burning until the heat declines. A lining of dry litter should be made round the bed to protect it from cold drying winds. Sow a little more seed, so that should an accident happen to the plants turned out others may be ready to take their place. *Garlic* and *Shallots*, where the soil is not wet and stiff they may now be planted, if not done in the autumn; plant in rows at 6 inches apart. *Kidney Beans*, a crop sown now in small pots, and when of sufficient size planted in a pit where a command of heat can be had, will produce more abundantly than those in pots; the introduction of the red spider into the forcing-house will also be avoided by adopting this plan. Keep those in pots well watered. *Lettuces* in frames to have air night and day if the weather is mild; sow on a sloping border to succeed the autumn sowing. *Potatoes*, where there is not the convenience of frames or pits plant on a south border for an early crop. *Khubarb*, pots may now be placed over the roots, and covered with dung or leaves. *Spinach*, a small sowing may be made between the rows of early Peas. *Turnips*, where young ones are wanted early a sowing should be made on a slight hotbed. Traps should be set in different parts of the garden to catch mice; they will now more readily take the baits than they will when there is other food for them.

FRUIT GARDEN.

Finish all pruning, digging, trenching, &c., in this department as soon as circumstances will permit. Newly-planted trees must be well staked and mulched if the spring is likely to be dry. A thorough drainage is essential to the success of every crop, now is a good time to push it forward.

FLOWER GARDEN.

The amount of delight and satisfaction which a flower garden is calculated to yield to its possessor will always be in proportion to the order and design which pervade it, to the unity of its parts in constituting a perfect whole, and to the amount of attention bestowed on the various details, constituting what is termed high keeping. What pleasurable sensations does the well-regulated mind experience in viewing a small garden replete with floral beauty and neatness! and, on the contrary, what powerful emotions do we feel in viewing an extensive place replete with "capabilities," but wanting the last touch of finish! Let us, therefore, remember, in all that relates to a flower garden, that order and neatness are indispensable. At this season of the year much must depend upon these qualities. The smooth and verdant turf, the fresh and neatly-raked surfaces of beds and borders, the flowing sweeps of walks displayed in well-defined margins of shadow depth, the walks themselves brimful of bright and warm-coloured gravel, the freshness and beauty of the evergreens unnumbered by faggots of dead wood; add to these thousands of Aconites, Snowdrops, and Crocuses just protruding their tiny heads cautiously through the soil, as if fearful of appearing prematurely, and we have the *beautiful* of what an English garden is in February. Grass lawns will now be much benefited by a thorough rolling, as also gravel walks. It may be worth while to know that a small

faggot consumed in the cylinder of the garden roller will heat it so as to prevent what is technically called "licking." When it is necessary, take up Azaleas, Rhododendrons, &c., and rearrange them according to their sizes. If it is wished to increase any choice kinds, layer a few branches now by pegging them down; this is the best time for such operations. If the soil is poor give it a good dressing of half-rotten leaves, which will enrich it greatly.

GREENHOUSE AND CONSERVATORY.

In the greenhouse proceed with the potting of young plants, and small specimens of all kinds, using the soil tolerably rough, with plenty of sand, and drainage, and keep them comparatively close until they take fresh root. This is a good time to start a collection of Kalosanthus, potting them in a compost consisting of two parts sandy turfy loam, one part turfy peat, and one of half-decomposed leaf mould, with plenty of coarse gritty sand, and a liberal admixture of charcoal and pebbles, or potsherds broken small. Give them a liberal shift, and keep them in a temperature of from 40 to 50, and as soon as they have made fresh roots stop each shoot, and train the plants into form. Attend to the training of Tropaeums, and other climbing plants, and shift the former into their blooming-pots if not already done. Plants of Polyala or B. roma, which are becoming too forward in their growth, must be placed in the cool end of the house. This is a good time to start a general collection of Azaleas, and no place is so good for them as a tolerably close pit partly heated by dung. Put them at the time of introducing them into heat, giving a liberal shift, into good peat and sand, to which a little thoroughly decomposed cowdung may be added. Increase the temperature of the pit gradually to 65 or 70, and maintain a moist growing temperature, with plenty of air in favourable weather.

STOVE AND ORCHID-GHOUSE.

In the culture of Orchids, the first point of importance is to secure a good-sized and well-matured pseudo-bulb; next to this is the preservation of all the roots in a healthy state. To effect this it is absolutely necessary with many plants that they should be grown on blocks of wood, either charred or not, but without any moss applied to them; and for the information of amateurs and beginners, it may be as well to give a list of the plants here alluded to:—*Phallopopsis amabilis*; *Barkeria spectabilis*; *Epidendrum Skinneri*, and *E. fuscum*; *Oncidium pubes*, *O. triquetrum*, and *O. crispum*; *Sophronitis cernua*, and *S. grandiflora*; *Leptotes bicolor*, and *L. violacea*; *Maxillaria Steelii*. The following also thrive much better so treated than otherwise:—All the Brassavolas, all the Lachias, all the Cattleyas, most of the small-growing *Oncidiums*, nearly all the *Epidendrums* and *Maxillarias*, and all the *Schomburgkias*. In giving new blocks to such plants as require them, they should always be chosen proportionate to the specimens they are intended to bear, and the heel of the plants must be placed close to the end of the log, so as to give as much space as possible for the plants to grow upon, for by growing them without moss the blocks in most cases will be found to last twice as long as if moss were employed. The plants must be made fast to the blocks by means of copper wire, and if they are shifted at the proper time very little fastening is required. The proper time to shift these plants is just before they make their new roots, which, of course, is at very different seasons of their growth; for instance, most Orchids make their roots while they are growing, but it is not so with the Cattleyas and Lachias; they, for the most part, make their roots after they have completed their growth.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Sowed Early Horn Carrots, Radishes, &c., on a slight hotbed, as alluded to last week. Gave plenty of air to Radishes and Lettuces coming on. The Cauliflowers injured by damp, alluded to last week, were not young plants, but those with heads fit for table. A few still remain, and Broccoli will succeed them. Sowed a lot of Tom Thumb Pea, and Sutton's Long-podded Tom Thumb, to grow in pots, and others to be transplanted under protection; also a few of Dillistone's Early Pea and Early Mazagan and Gem Broad Beans for transplanting out of doors. Dillistone's is a few days earlier than Sangster's No. 1; but of all early Peas that we have seen there is none with us that equals Sangster's in productiveness. The next best Pea for earliness and productiveness, though coming in fully a fortnight later, is Dickson's favourite. Our other work

was much the same as detailed last week. The change of the weather has enabled us to proceed with digging and trenching what little spaces we have unfurnished in the kitchen garden. The Dalmeny Sprouts, though not equal to other Brussels Sprouts at this season, furnish a nice tender little Cabbage on the top of each stem, as tender when cooked as a nice Colewort, and seemingly much hardier, and there is every appearance that from this kind the sprouts will come firm and late after those of other kinds have begun to run. In answer to a lady who has sent a note on the subject, we would say, Use the common Brussels Sprouts for a winter supply, and these Cabbage-headed Sprouts for spring, at least that is the impression produced on us by what ours promise to be. Brought home a few leaves, and find that the high winds will leave us short of fermenting material this season. But for this would have had lots of Potatoes on beds before now. At present our forward stock is chiefly confined to pots; but before this appears we most likely will have started some beds under frames, with just a little heat beneath them, which is generally safer than having too much. A quantity in pots are, however, in excellent order.

FRUIT GARDEN.

Had some trouble with our stokeholes, protected merely by a flap door, as the heavy rains soaking through the ground found access to them. We fear also that the drains could not, or would not carry off the water sufficiently. We have made arrangements to carry off all the surface water from them, but still we did not escape altogether, and fear that the dumb well into which the drainage goes must itself have become full. We had one stokehole, about 6 feet deep, in the Melon ground, that used to annoy us very much, though to keep the place tolerably dry a dumb well had been sunk in the chalk below the clay to the depth of nearly 50 feet; but in heavy rains the well used to be filled, and when the water rose above the stokehole level, that too was filled, and if we wished the fire to burn we had to lower or empty the well. Now we take all the surface water past the well, collect it in shallow cesspools, and take it from thence by pipes into a pond made on purpose, and thus we obtain a fine supply of water and escape a flooded stokehole. A vast quantity of water may be thus collected from hard, gravelled, and, better still, asphalted paths in a Melon ground. Having known what it is to be without water, and to use for plants what they ought never to receive, we have regretted to be obliged to drain away so much water this season, that would have been invaluable in summer could we have kept it.

Went on with pruning out of doors, as we could attend to the trees, and trying almost every device to keep birds from the buds; but we were, nevertheless, often obliged to confess ourselves beaten. It is vexing after the trees are bristling with fine buds, to find all the most forward and best destroyed. On the top of a small Thorn tree, the head about 15 feet above the level of the Laurels, and perhaps 12 feet in diameter, we counted the other morning just as daylight was coming in, 250 little birds, and that was not all of them. Every Laurel bush is crowded at night. Poor things! whilst alive they must find food. With all our sympathy for small birds, it is possible to have too many of them.

Gave plenty of air to Peaches opening their blossoms, and treated other houses much the same as detailed in previous weeks. Were we in this respect to listen to all hints, for which, nevertheless, we are much obliged, we would in one case just state every week every little thing that had been done, though that would be mostly a repetition of what was said the week before, or we would never repeat at all, and only write when we had something new or fresh to say, which would be very seldom indeed.

ORNAMENTAL DEPARTMENT.

Looked over half-hardy plants in cold pits and frames. In the pit where *Calceolaria* cuttings were inserted in the end of October and the beginning of November, we find all are growing now—scarcely one has failed. Wednesday being a fine day, pulled out the few weeds that were among them, however small, a very few decayed leaves, and then pulled a pointed stick between the rows, so as to loosen the surface soil a little. This will help them under any circumstances, but it will help them most of all if we should be obliged to shut them up in a continuous frost. If we had the chance we would be inclined to change cuttings with some friends as respects many bedding plants. We believe that even in their case a change from different soils is beneficial. From the bloom being very freely

produced, and then from the heavy rains in autumn, we did not obtain so many cuttings of *Anrantia multiflora Calceolaria*, nor so good, as we liked, and we obtained a batch of cuttings from a friend in the neighbourhood; and even now in the cutting-bed we can see how far these cuttings extend, as they have a rich luxuriant green about them, which the others do not exhibit, though treated in every way alike. We have no fault to find with the others, but still these look better, and must soon be thinned, otherwise they will injure each other. As far as we recollect, these *Calceolaria* cuttings received very little shading, and no regular watering since they were watered when they were inserted. We have no doubt that many of our bedding *Geraniums* that do well would do better still could we manage to exchange cuttings with another place at a little distance. Even in the cutting-bed these *Calceolarias*, which seemed not the least different from our own, are quite conspicuous now; and we believe, taking the evidence of the past into account as something like a guarantee for the future, that they will be more vigorous in similar circumstances throughout the summer. The difficulty in effecting such exchanges arises merely from the fact that many gardeners could take what cuttings they liked by the middle of August, whilst in other cases where there was a resident family it would be difficult to make many cuttings of bedding plants until September or October.

Potted a lot of *Fuchsias*; pruned more, to prepare them for potting after breaking. Cuttings inserted now will make nice flowering plants for the autumn. A little bottom heat is a great advantage for fresh-potted plants where it can be given them. Brought in the most forward *Caladiums* that were potted in small pots; and after potting afresh in larger pots, plunged them in a mild bottom heat. The others will be potted as the first pots fill with roots. No plants are more benefited by a little bottom heat. To have them in perfection they should be grown in a platform or bed, where a bottom heat of about 10° more than the atmospheric heat can be given them. The leaves will then have a size and a richness which they seldom possess when standing on a shelf with the pot exposed, and no bottom heat. Proceeded also with potting fresh Mosses and Ferns, and those of the latter especially, which, after having the decaying fronds cut down, were beginning to break afresh. Many Ferns are especially beautiful when the fronds are young. Many small Mosses, as *Selaginella apoda*, can only be kept fresh and vigorous by frequent division and potting. When full grown and let alone, a drip will cause pieces to fade and decay. Either for small plants or cut flowers in vases such small Mosses become exceedingly useful. In covering pots in small vases, the short green moss found on trees and rocks is also very useful, as these hardy mosses stand the dry heated air of rooms much better than those brought either from the greenhouse or the hothouse. Were we a lady or a gentleman with any pretensions even to fitness in taste, we would not have a flowering plant in a pot in a room, unless the common pot were concealed in a vessel whose artistic merits were in unison with the surrounding furniture. We know that some ladies are very clever in dressing in various ways the outsides of common pots in handsomely-furnished rooms; but too often the makeshift is easily seen, and that spoils the effect. For window and room plants see last week.—R. F.

TO CORRESPONDENTS.

*** Many interesting communications are in type, but omitted for want of space. We purpose giving another Supplement next Tuesday, which will enable us to publish them.

ROSES TO BLOOM IN JANUARY (*William*).—Having no convenience for forcing, you can only have Roses in bloom at this time by cutting the plants in after they have done blooming in summer to four and not more than six leaves, and they will push and show for bloom in autumn. You must then prevent their flowering by keeping them on a north aspect until November, when they are to be removed to a light, airy, cool house from which frost only is excluded, and they will then give a few blooms late.

TAKING UP STRAWBERRIES FOR FORCING (*Idem*).—You may take up the plants, and, making sure of a ball, put them now, plunging the pots to the rim in ashes in a warm sunny exposure, and early in March place them on the shelf of your greenhouse. They will give you a good crop of fruit if they have good crowns.

BOOKS (*T. B. H.*).—Mills on the culture of the Melon. "The Kitchen Garden Manual" contains full directions about Cucumber culture. It can be had free by post from our office for five postage stamps.

LIQUID MANURE (*Thomas Earne*).—All kinds of liquid manure should be applied only when plants are growing. Your pie-stye drainage may be applied undiluted to vacant ground where Cabbages are to be planted, but if watering plants one bucketful should be mixed with six bucketful of water.

PROPAGATING GERANIUMS. (*A Little Geranium*).—Your Geraniums that have not been cut-in will now give a cutting from the point of every shoot, and you may trim plants by taking off cuttings and potting them in small pots. Plunge these in a hotbed of 75 for three weeks, and the cuttings will be well rooted. Your propagating-pot will admirably for them, and if you do not put in the cuttings until February, or early in March, they will root with more certainty. The cuttings will each give a cutting if you continue them in heat, and the old plants will afford a second lot of cuttings in number about the double of the first; you may facilitate their doing so by placing them in heat after taking off the first lot of cuttings, and keeping them there until the shoots be sufficiently long. If you take off the first lot in February, the old plants and the first cuttings will afford more cuttings early in April. They strike freely in gentle heat. When struck they should be removed to the greenhouse.

GERANIUMS IN BOXES AND PANS. (*Idem*).—Do not pot them from the boxes and pans until the middle of next month, and not until the middle of March if you keep them in the greenhouse after potting. If potted in February they should have a temperature of from 50 to 55, at least, to induce them to root well and become quickly established in the pots.

PROPAGATING LILIES. (*Idem*).—The only objection to be taken to your arrangements is that the lily being so enclosed in the heat will be too much confined, and will warm that in contact with it, rather than the atmosphere by ascending through the drain tiles. Were you to have a chamber made over the lily, and the tiles communicating with it, then the heat would rise sufficiently through the drain tiles to maintain the atmosphere at a suitable temperature. The other arrangements are good. You will require a plant at every 2 feet 6 inches, the plants being trained to the roof, and from 9 inches to a foot from the glass. Over the dune-bed should be 1 foot of good rich turfy loam for the Cucumbers to grow in. Ferns would do well, the shade of the Cucumbers being sufficient for them.

RHODODENDRONS FOR FORCING. (*Idem*).—Rhododendron catalpaense, var. Everestianum, Ghanyamum, Jaekmanni, Lindsayum, Standishii, and deheats-mum; K. kir-utum, K. odoratum, K. myrtillofolium, K. canescens album, K. Eusebianum, Ratasanganum Victoria, R. Ratasanganum, R. Blundyanum, and R. genuiferum. These are good, as are all the R. nobilium var.

RHIZOME COMMENTS FOR PLANTING OFF STRONG. (*N. D. Bulbous*).—Sow the seed early in February in the smallest pots, one or two seeds in each, using a compost of light turfy loam two-thirds and one-third leaf mould, just covering the seeds with fine soil, planting in a bottom heat of 75, and keep the soil moist. Let the pots continue plunged until May, potting the plants as frequently as they fill the pots with roots, and gradually hardening off so as to turn them out early in June.

CUSTARD APPLE. (*Idem*).—It is not a native of Madeira but of Brazil. It is grown extensively in Madeira, also in the East and West Indies. We are not aware of its having been successfully grown for its fruit in this country; if it has, we should be obliged for particulars of its cultivation.

SOIL FOR CUCUMBERS. (*Idem*).—The best compost for Cucumbers is that formed of turves taken from yellow loam of good medium texture, cut 3 inches thick, and placed for twelve months in alternate layers with fresh horse droppings. Turn the whole over twice, and mix with it at the last turning a bushel of soot to every cartload. This, chopped with a spade and made fine, will grow Cucumbers better than anything we know of.

GRAPES FOR MARKET. (*A. S.*).—None are so marketable as the black varieties, and you had better have none other than Black Hamburgh and Lady Downes Seedling.

FUNGUS ON BEANS. (*Beckham*).—It is quite impossible to detect the fungus from such a smashed fragment. It seems like young Mushrooms suddenly checked in their growth—certainly not Truffles.

LANDSCAPE GARDENING. (*W. Williams*).—London's edition of Repton's work on Landscape Gardening.

MEAL RUB ON ORANGE TREES.—In the Journal, issued January 16th, "H. T." is recommended a process for cleaning his Orange trees from mealy bug. Mr. Carson, of Melbourne, showed that Orange trees in Australia, where blight appears to be much more vigorous than in England, were restored to health by means of Gishurst compound. Perhaps "H. T." will operate on one of his trees as follows:—Rub a wetted painter's brush over the Gishurst in its box, then pay the thick lather well over all the infested part of the Orange tree. The result will, I believe, be as successful as that from the treatment recommended in the Journal, while the Gishurst treatment has the advantage of being simpler and more quickly performed.—G. W.

BOG PEAT. (*T. B.*).—If you require such as is used for fuel we do not know where you can purchase it in London. If you mean the bog earth, or heath, it is used for potting, any nurseryman would supply you.

WALTONIAN CASE. (*A Medical Man*).—We do not know where these cases can now be procured. If you can apply gas to it, a Bijou Plant Case, made by Mr. Stokes, Cabinet Maker, Archer Street, Bayswater, would do for striking cuttings.

FUCHSIA IN WALL. (*B. S.*).—Souvenir de Chiswick is a good dark, and Bose of Castle a good light corolla'd free-growing Fuchsia. The only aspect suitable for them out of doors is a south one, and there they will require to be covered up in winter to protect them from frost, and the surface of the ground must also be covered with 6 inches of litter to protect the roots and crowns from frost.

MOSS ON GRAVEL WALK. (*Eques*).—When the surface is frozen hard brush the green places heavily with a half-worn broom, and it will clear away the moss. The best remedy is to turn the gravel, and March is the best time for you to do it. Salt strewn on the green places will kill the moss, making the surface quite white as if a snow shower had fallen. It also renders the walks damp.

PLANTING BOX FLIES. (*Idem*).—It is necessary to take off the slip with a portion of root to them. Your box being old, it will be necessary to plant it deep. All the lime-stem pot should be inserted in the soil; to make sure of growth the slips must have roots. Two inches of the growth of last year will not do well.

APPLE AND PEAR PITS SOWING. (*Lauffen*).—Your plan is good, and we are anxious to improve upon it. They will do better without the frame that you fit.

SEEDS FOR A HALF-ACRE GARDEN. (*Idem*).—It is very difficult to state what might be the cost of seeds for such a garden for one year, unless we knew the habits and wants of the family. We once knew a case where a gardener paid as much for small 8 shad seeds alone as his neighbour did for all the seeds he wanted, and both places were of about the same size, and economy and far dealing were exercised in both. We may say, however, that allowing a fair price for all the seeds wanted, with a quantity of such articles as Garlic, shallots, and sweet herbs, altogether about 45 might be allowed. This opinion is of course given in the absence of all information as to the special wants of the family, and every family has wants especially its own. We cannot, however, hold out much prospect of many seeds being saved in a garden; the appearance of the plants, when in a seed-ripening condition, is rubbishy, and seeds are better saved on a large scale than in patches in a garden that may be visited any day, perhaps, by the family. Most gardeners, however, pride themselves in saving anything that is especially good in the way of Celery, red Beet, or late Broccoli, and now and then a good Lettuce, perhaps, and a batch of Dwarf Kidney Beans or Scarlet Runners that have not been all wanted, are allowed to ripen their seeds; but, with these exceptions, and any other vegetable that is especially good, gardeners may find more profitable employment than attending to small parcels of seeds. When we say that most market gardeners, whose living depends as much on their savings as on their gain, buy their seeds instead of growing them, we hope employers of gardeners will see the imutility of enforcing this rule too far.

GAS TAR FOR DESTROYING RED SPIDER. (*Idem*).—Gas tar applied to hot-water pipes when hot will emit fumes that will kill red spider and the leaves of plants as well, unless the latter are mature, when they will not be injured; and this, we think, must have been the case in the instance alluded to by "Nemo." viz., the leaves of the plants infested with red spider were so fully matured that nothing short of an absolutely destructive agent would injure them. If you apply gas tar to hot water pipes when they are cold you will find that when they are heated fumes will be given off that will injure the joints of the structure, and if it be applied when the pipes are hot, and they are maintained hot until dry, the fumes emitted will kill every immature leaf of immatures of the plants in cultivation; but, after it has become dry, if the pipes are not heated more than they were when it was put on, no fumes will result. When the gas tar is applied to a flue as hot as it can be made, the fumes will be given off rapidly, and the tar on becoming dry will not emit fumes until the flue is made hotter than it was when coated with the tar. The fumes will kill the immature leaves and growths of all plants if sufficiently powerful, but if the leaves are mature—as for instance those of Vines, the fruit of which is commencing to colour, the foliage will not be injured to any great extent, unless the fumes are very strong. When the woodwork of a house is painted with gas tar, the fumes are not powerful after the tar has become dry, but every time the sun heats the boards more than they were heated when the tar was applied fumes will be given off, and this we have found to be the case for two summers after the application, and in the third there was often a bad smell when the boards were heated by the sun's rays. The fumes of gas tar are injurious to vegetable life, and are too uncertain and dangerous an agent to be used as a destroyer of the insect pests of a garden.

ALTERING PITS. (*A Non Subscriber*).—The height of the walls of the pit you propose altering must be in proportion to the plants you wish to forward in it. For a pit 10 feet in width, and 32 feet long, and for which you wish to have bottom heat and top heat from flues, the brick wall may be 8 to 9 feet, and the front wall from 4 to 5 feet high. The simplest plan would be to sink the furnace at one end, take the flue beneath the proposed pathway, or in front of it, and take it out at the other end, or return it to the same place. This simplicity must be departed from if you resolve to make the pit into two distinct little houses, to be heated separately or together. By having the furnace at one end, you could heat the part next the furnace without heating the further part, but you cannot heat the further part without also heating the nearer part. To heat either at pleasure, and from one fire place, the furnace had better be placed at the middle of the back wall, and so low that the furnace bars shall be 18 inches at least below the level of the pathway at the back, and quite as much below the base of the flue. The furnace should be rather roomy, and from it, on the slant, take two flues, one for each horse, taking both below the pathway, say for 3 feet in width, and then raising the flue wholly above the level of the floor. These flues should be neatly fitted with strong dampers near the furnace, so that the heat may pass into one or both as desirable. Suppose that you allow from 24 to 3 feet for a passage, the rest of the space may be shut off by a wall from 2 to 3 feet in height, forming a pit in front. If you wish the flues concealed, along this pit they must go, and, if much heat is wanted, return and pass beneath the pathway into the chimney. From the necessity of thus descending to reach the chimney you will have to raise that higher, say from 12 to 15 feet. The flues should be at least 1 foot in depth, and 9 inches wide, inside measure. If you make a chamber, the bottom of which will be 6 inches above the top of the flue, all will be easy, as you have only to leave openings into that chamber so as to obtain what top heat you want out of it at will. It would be well to have such flues for 9 feet nearest the furnace, brick on bed instead of brick on edge. Spaces for cleaning should be left at the ends. It has several times been stated how the spaces between such flues, and from them to the walls, might be filled loosely with clinkers, stones, bats, &c., and for 5 inches above them, and then finished with fine gravel, with drain pipes set upright back and front so as to let heat up at pleasure, and also pour water down among the rubble when necessary, without going on the flue, which must be avoided. Anything may thus be done with the old-fashioned flues, so long as they are sound. For Cucumbers and Melons use from 18 inches of soil, with a little rubble below it, which you can water without drenching the soil, for excess of dryness at the bottom must be avoided. The Cucumbers should be 15 inches from the glass. In changing the height of the walls the ventilators should be made in the walls, and then there will be no necessity for moving the glass. Where a high temperature is wanted large ventilators are not needed. A foot of air under each light, back and front, would be ample. A few inches would often be enough, as when the sun was high you would need little fire heat.

PEACH TREE BUDS DROPPING. (*G. S.*).—This is generally owing to extra ripeness of wood, dryness of the roots, and dryness of the air; but, if the dropping is only in moderation, it just does for the trees what had often better be done by the gardener. There is no doubt that washing the trees even with soap and water, let alone Gishurst compound, also un-

settles many of the buds, and whenever a stimulus is given to extension they drop. Those out of doors are free from some of these casualties, but how often does it happen that many buds, if they stand, are defective. Washing, and dryness at the roots are the chief causes, but, if the dryness is not excessive, there will generally be enough of buds left. We have often heard gardeners lamenting about their buds falling in March, and then in August lamenting that they had left so much fruit.

RUSTIC BASKET-MAKING (H. B., Lancashire).—It is a trade, and we know of no one who would furnish the information.

TWELVE SELECT VARIETIES OF AZALEA INDICA (Jack).—Holfordii, Standard of Perfection, Delecta, Glory of Sunninghill, Magnet, Gem, Stanleyana, Gledstanesi, Iveryana Improved, Flag of Truth, Criterion, and Etoile de Gand.

CYCLAMEN PERSICUM BLOOMING BADLY (Idem).—They have this year, more than usually, a peculiar twist of the petals. Whenever we see this we are sure the plants will be unusually prolific in seed. Give them weak manure water at every alternate watering, and it will help to make the petals broader.

SUPPLY OF EARLY VEGETABLES (T. Doenges).—When there is plenty of glass and plenty of heating power, gardeners generally do manage to have many crops coming on at the same time, though it would require extra management to have Potatoes, Rhubarb, Sea-kale, and Cucumbers in the same place. Our remarks had reference chiefly to those with limited means, and would tend to show how such vegetables as Rhubarb and Sea-kale could be had in plenty where neither light nor heat could be given for Cucumbers. At this season of the year many farmers, and those keeping a horse, might have Sea-kale and Rhubarb, but could not give the supervision and care that would be necessary for Cucumbers. Whenever a heat of from 50 to 55 and 60° can be maintained, though the place be in darkness, these vegetables and Mushrooms may be obtained. We have had all these doing well in a small house, used for store plants in winter, and also for Cucumbers, but the house was constructed a little singularly in this way:—It was about 20 feet long and 11 feet wide, had a broad shelf and path all round, and a platform in the centre, under which was the tank that heated the house, formed of wood and covered with slate. The tank was supported on arches, and the openings to the arches were fitted with boarded doors, easily moved by a handle. Beneath the tank, in these shut-in arches, the temperature was much lower than in the general atmosphere of the house, and there Mushrooms, Sea-kale, and Rhubarb were first-rate, and with little more trouble than putting in the roots of the last two. There is little danger of Kidney Beans damping where they can have dry heat. Your plan is often adopted. We have tried your plan of planting the tops of Potatoes, but we have not previously heard of its being resorted to as a general practice.

PLANTS FOR NORTH AND SOUTH ASPECTS (J. R. N.).—For your north aspect nothing would answer so well as Ivy, of which *Hedera Regueriana* is fine, two plants of which would cover that desired better than anything we know. If these are objected to, *Crataegus pyracantha* and *Cotoneaster Simmonsi*. On your south aspect, 25 feet high, *Magnolia grandiflora*, and the Exmouth variety of the same. These are not climbers, nor, indeed, are the two preceding, but you confine us to evergreens, and there are not many of these suitable for covering high walls.

RENOVATING VINE BORDER (R. C. S. H.).—Your proposed plan of removing as much of the soil from the border as you can, and replacing it with rotten sods a year old, is good; but, instead of mixing large pieces of bone

with the soil, use boiled half-inch bones, and do not cover the roots more than 6 inches deep. A quantity of leaves and fresh litter laid on the border to the depth of 2 feet will do more to bring the roots to the surface than a deeper covering of soil. We think the bunches and berries would have been finer if a less number of the former had been allowed to remain.

DAPHNE INDICA CULTURE (Reginald).—Provide good drainage, for if that is not secured the plant soon loses its roots, assumes a sickly appearance, and eventually dies. In potting use a compost of turfy sandy peat and turfy yellow loam in equal parts, with one-sixth of sand intermixed. Care should be taken not to over-pot, for the plant seems to thrive best if rather under-potted; and it should not be over-watered, for, if the soil be kept too wet, it will perish; allowing the soil to become dry is equally injurious. Do not place the plant in a moist growing heat after blooming, but in front of the greenhouse where it can have plenty of air, which all the Daphnes require. We think your plants perish from placing them in a greenhouse fernery, which is no place for flowering plants, much less for those requiring, as this Daphne does, abundance of air and light. Placing the plants out of doors in a shady position to ripen the wood is all wrong, for plants in the shade can never have the wood ripened, and, the pots being exposed, the evaporation from their sides will dry up the roots and destroy the delicate fibres of these. If the pots are plunged the soil is apt to become too wet at times. For the plant to bloom well it requires a temperature of from 50° to 55°, and an abundance of air and light after the growths have been made, in order to ripen them thoroughly.

PLANTS FOR BACK WALL OF CONSERVATORY (A. K. N.).—Heliotropes used to be excellent up and around the pillars of the conservatory at the Grange—Lord Ashburton's. These might be varied with such plants as *Jasminum gracile* and *revolutum*, and *odoratissimum*; a *Fuchsia* or two, and *Habrothamnus elegans*. For rafters: *Passiflora corulea*, and var. *Colvilli*; *Kennedya Marryatæ* scarlet, *monophylla* purple; *Rhodochiton volabile*, *Bignonia chirera*, *Plumbago capensis*, *Sollya heterophylla*, *Fuchsia microphylla*, *Passiflora alata-cornuta* purple, *Bignonia jasminoides*, *Sollya angustifolia*, *Brachysema latifolia*. For large hanging baskets choose three or four different coloured *Manranthias*; two of three varieties of *Lophospermum*; one plain-leaved and one variegated-leaved *Cobaea*, and four varieties of the *Propagula*, of the Lobbianum and elegant varieties. For smaller more lasting baskets choose such as *Cactus Malleoni* and *ingeliformis*, *Saxifraga sarmentosa*, *Hibbertia grossularifolia*, *Tradescantia zehriana*, *Arctotis argentea*, *Kennedya prostrata* and *coccinea*, *Lobelia* of the gracilis and *hegonifolia* varieties, and *Verbenas* of the trailing habit of *pulchella*. *Achimenes* do very well in summer.

NAMES OF FRUITS (Rev. J. P. L. Pine).—Augustus Pearmain. (M. S.).—Pears: 1, *Beurré d'Arcenberg*; 2 and 4, *Passé Colmar*; 3, *Beurré de Rance*; 5, *Beurré Diel*; 6, *Napoleon*; 8, *Easter Beurré*. No. 1 Apple, *Braddick's Nonpareil*. (J. E. Betley).—Apples: 1, *Lewis's Incomparable*; 3, *Northern Greening*; 4, *Augustus Pearmain*; 6, *Golden Knob*; 7, *Gloria Mundi*; 10 and 12, *Tower of Glanmis*; 11, *Federal Pearmain*; 13, *Braddick's Nonpareil*.

NAMES OF PLANTS (Aricoba).—1, *Goldfussia isophylla*; 2, *Jussia speciosa*. The *Heath in flower* is correctly named. (C. P.).—1, *Pteris* sp., too young for identification; 2, *Adiantum capillus-Veneris*; 3, *Polystichum angulare*, var. *proliferum*. The other plant is a *Solanum*, but the scrap sent is insufficient for determination. (J.).—*Asplenium bulbiferum*, var. It should be kept in a coldhouse. (Fern).—1, *Adiantum capillus-Veneris*; 2, *Ceterach officinarum*; 3, *Cystopteris regia*; 4, *Scolopendrium vulgare*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending January 27th.

DATE.	THERMOMETER.						Wind.	Rain in inches.	GENERAL REMARKS.
	BAROMETER.		Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

GAME BANTAMS.

"Of Game Bantams actually ninety-nine pens! Why is this? First, they are easy to breed. . . . I own I think shows are becoming overburdened with these easy-to-breed miniature Game fowls. . . . I am thoroughly jealous of the number in which Game Bantams muster." I extract the above from "WILTSHIRE RECTOR'S" "First Impressions of Bingley Hall," published in your Journal of the 16th inst. Let me ask if "WILTSHIRE RECTOR" has ever been a breeder of Game Bantams. I should say, Certainly not, or he would not have designated them "these easy-to-breed miniature Game fowls;" or, if he has, his birds must have been as he says, "one as good (or perhaps, more correctly speaking, as bad), as another." I have in my time bred hundreds of Black-breasted Red and Duckwing Game Bantams, as well as all the varieties of Ham-

burghs, Cochins, Brahmas, &c.; but my experience is, that so far from Game Bantams being so easy to breed, they are by far the most difficult variety I have yet attempted. He may consider himself indeed a lucky fellow who can obtain one good bird from a hatch. Without exception, every fancier of Game Bantams that I have come across (and I think I know the majority), agrees with me that they are a most difficult variety to breed really first-class birds from.

Again. Let me ask "WILTSHIRE RECTOR" if easily bred birds would fetch £25 per pen, and cocks and hens from £10 10s. to £5 5s. each, as we often find Game Bantams do? Nor will I allow that they are unprofitable, for they are very small eaters. They muster so strongly at every show, that the committees are bound to give them good prizes; they are so light, that the expenses of carriage to exhibitions are trifling compared to other varieties; and lastly, a really first-class bird will any day command a first-class price. Why, then, should "WILTSHIRE RECTOR" desire to see these popular pets go out of fashion, and give place to inferior Blacks and worse Sebrights? That

they may long continue to hold the high position they have so justly gained is the sincere wish of—GALLUS.

["GALLUS" properly enough might have asked if I had bred Game Bantams; yet he, not being of my acquaintance, had no right to answer his own question by a "certainly not."]—

Well, I will reply quite openly. I have been a breeder of Game Bantams, and that of recent years, but gave them up for Blacks. I have also been watching the breeding of these birds for the last two years at a house not more than two hundred yards from my own rectory, also in a town near me on a still larger scale; and I inspected a yard of some fifty birds quite recently, these being Black-breasted Reds, and I marked also the result in another instance. Now for the conclusion I came to. Duckwings I found were apt to run out of colour; the hens came sometimes salmon instead of silver-grey, and the cocks too dark, and also mottled-breasted. But the Game Bantams which appear in by far the greatest numbers are the Black-breasted Reds. At Birmingham there were sixty-seven pens of these, and only twenty-five of Duckwings; and at other shows I have seen even a greater disproportion—at small shows many Black-breasted but no Duckwings at all, or but one pen. Manifestly, therefore, when I spoke of shows "becoming overburdened with these miniature Game fowls," it was to Black Reds that I mainly referred.

Now I aver that these are easy to breed. In proof: A friend of mine purchased a pen last spring through an advertisement in this Journal. The price was not very large, but the advertiser was an honest man—not one of the "shabby," equivocating, deceiving gentry, so his birds were good. Every egg laid was put under some hen or other, and a vast proportion were hatched and reared. In November last I saw them, and a great number they were, yet not one had run out of feather; every one was willow-legged, and among them were prizetakers at different shows. I also aver that a large number were of equal goodness, yet this gentleman was contemplating killing them wholesale, not knowing what to do with them. Again, high prices are no guide in anything that only depends on fancy. Did "GALLUS" never hear of tulip bulbs selling for a small fortune during the tulip mania? or of the sailor who ate one and thought it a bad onion, and the enraged owner would have cut the sailor open had he but swallowed the tulip whole? Committees must award prizes for whatever varieties of fowls muster in any great number, from whatever cause. In poultry, popularity rests upon two bases—usefulness and fancy; the former a permanent basis; the latter anything but permanent.

I do not desire to see any variety of fowls "go out;" hence, though there is little to recommend them, save former fancy, I hope even Malays will not entirely disappear from our shows; and I have endeavoured to speak a word for Polish, a sort too much neglected, for surely they are very beautiful. I am sorry, likewise, to see Schrights declining in number; yet, when good, as regards the beauty of feather no kind of fowls can be compared with them for a moment; they at once attract all eyes, especially those of the ladies, who generally understand beauty of feather and colour a great deal better than we do. I am sorry that other real Bantams are by no means numerous. I am not insensible to the beauty of miniature Game fowls, although I think their beauty inferior to real Game, because in them we see power as well as courage, the might of muscle as well as the courage of will. Bantams, the so-called Game, are not. The word Bantam is now an old English word, and implies a consequential strut, broad full breast, and a drooping wing; and these the Game of course must not have; but in all other Bantams these properties are seen to perfection. I have kept all kinds of Bantams, even Nankin and Partridge. The only sort I found profitable (I am setting aside fancy prices), were the Blacks: they never wander and get killed or lost; they lay well in winter, if pullets, and I wish I had not parted with them, for from my Coelins I had no eggs in October, November, and December, when fresh eggs in Bath were 2½d. a-piece, whilst from Black Bantams I always had eggs during the months mentioned. If "GALLUS" has a large number of Game Bantams for sale, I fear they will hang on his hands, or sell for little. Fancy, their only supporter, is a changeable as well as imperious deity, and looks out constantly for something new, and lacking that, turns back to old loves.—WILTSHIRE RECTORY.]

MILINESS OF THE SEASON NEAR LUTHER.—I observed this morning, 23rd of January, my bees busily gathering pollen, from, and humming joyfully about the flowers of the laurus-

tinus, of which beautiful evergreen I have a hedge now in full bloom.—W. L. L.

NEW BOOK.

The Poultry-keepers' Manual; containing descriptions of all kinds of Domestic Poultry, with Instructions for their Management, and their Treatment when Diseased. By CONTRIBUTORS TO "THE JOURNAL OF HORTICULTURE AND POULTRY CHRONICLE." With Twenty-two Coloured Engravings and Numerous Woodcuts. London: Journal of Horticulture Office. 7s. 6d.

"NUMEROUS inquiries for an easily consulted work on Poultry, having coloured portraits of the varieties, showed that such a publication was needed. This, combined with the abundance of communications in our possession from most of the best authorities on Poultry-keeping, induced us to prepare the present volume. Its contents, therefore, commend it to all who require such a book for reference."

To the above copy of the title-page and extract from the preface, we will only add that the volume combines information from most of the best-known poultry-breeders, and is so arranged as to be most easily consulted on any subject connected with poultry.

QUEEN ENCASEMENTS.

I AM glad to notice that your excellent correspondent, "R. S.," has taken up the subject of queen encasements. I hope he will continue to note the cases that may occur in his apiary, and give us the benefit of his experience and observations.

Since my last communications on this subject, I have had several additional cases in my own apiary, one or two of which I shall mention; but before doing so, I may here state, that in advancing the opinions which I then did, based though they were upon close study and diligent observation, I was not unaware of the difficulties of arriving at a true solution regarding some, at least, of the cases alluded to. These were put forward in a form somewhat hypothetical. Future observations on the part of others as well as myself may probably lead to resolving some of these within a narrower compass, and, it may be, upon a simpler basis; but in order to attain this end, the subject is one which requires the closest attention, and a complete acquaintance with the history and character of the queens so treated. I quite admit, therefore, the pertinency of the remarks of "R. S.," in calling upon me to explain "by what means" I had ascertained the ages of some of the queens referred to.

In an experimental apiary like my own, where many of my queens have in my various manipulations to pass frequently under review during the season, it is not at all impossible to note peculiarities and distinctions, not more so, I imagine, than with a Pigeon fancier, or a rose amateur, who can by the turn of a feather, or the form of a petal, see points of difference in apparently the same objects. In my apiary at present stand some thirty hives, and I acknowledge myself to possess a pretty good acquaintance with each *materfamilias* throughout, and on all occasions know as certainly when any change of government takes place in a hive, or when a young princess ascends her apian-throne, or, which is much the same, when the celebration of her nuptials occurs, as if a royal salute were fired overhead from the cannon's mouth to announce the fact. Nor do I claim to myself any extra knowledge over other close observers, if in regard to not a few even of the black monarchs in my apiary I could say, In this hive reigns a queen moderate in size, and dark and sombre in colour; in that a smaller one, but darker still, and fleet and agile; there an aged sovereign with ruffled wing and tottering step; here a liliput, scarce distinguished in size from her less-honoured sisters, the remnant of an artificial batch; and there in yonder hive reigns a monarch worthy of the name, large, noble, magnificent, "born to command," whose every step is grace, and every movement majesty; there, too, is a worthy rival, superior far in beauty and colour, whose saffron hue and golden tinge might well claim a closer kindred to the still more beautiful Italian. No, no, I cannot admit that there are no queen distinctions, and that it is impossible for us to note them. This, then, is my reply to "R. S." in his remarks on this subject. Every scientific apiarist should have as intimate a knowledge of the history and character of the queens in his apiary as Miss Strickland has with the Queens of England.

Those cases of queen encasement which have occurred in my apiary during the past season, I could trace, with only one exception, to the entrance of stranger bees. Of this I have not the remotest doubt, and it will be remembered this was one of the conclusions at which I had formerly arrived.

The exceptional case first. I had brought to my apiary in July last, a magnificent hive of black bees presided over by one of the largest queens which I think I ever witnessed. Its inmates I drove, and lodged in an empty Huber, and I gave the hive, teeming with worker-brood, to a Ligurian swarm. Coming from an early locality every drone had been extirpated, and no drone brood even was in the cells. To aid comb-building, I fed with honey and sugar syrup, and brood-rearing proceeded at a rapid rate. Towards the end of August I noticed symptoms of the queen's encasement. I opened the hive, and found the magnificent queen imprisoned, and in fetters, for what reason, alas! it did not appear. I simply examined the prisoner, and left her in this instance to her fate, knowing how little good sometimes follows any interference. Two days afterwards, however, observing that she was still the object of persecution, I again opened the hive and released her on two several occasions, but introduce her where I might, her reception was of the same character. I ultimately closed the hive, and left matters to their natural course. Next day the queen disappeared, and I was under the impression that she must have taken flight in disgust, as no trace of her could be found. On examining the hive I found three royal cells well advanced. I then introduced a whole swarm of bees with their queen to see what would follow. A great number were killed, and the queen was rigidly imprisoned. Seeing this I immediately cut out all the royal cells, and on examining the interior next day, I found the queen was at liberty, but the bees very excitable and furious. As I know not this queen's antecedents, I merely state the case without comments.

Another case occurred in the straw hive into which I had introduced the Ligurians above referred to, after being brought back from the heath in the middle of September. It was placed on a site occupied by bees which were previously joined to another hive. The population being Ligurian, I had reason to feel satisfied that several of the former occupants of the site had found entrance. The queen was encased, and I drove the bees to try the releasing system once more. It temporarily succeeded, content seemed to prevail, but the next day witnessed a recurrence of the same state of things. Wishing to try the effects of isolating the queen for some time, I again succeeded in extricating her from a cluster at the bottom of the hive, and confined her twelve hours in a wire cage, which I placed under the hive. After releasing her I introduced her at the top orifice, and she descended among the combs pursued by the bees. During the night the queen had escaped, as I found her next morning lying benumbed and motionless in front of the hive. I first thought she had been extruded dead, but under careful nursing she gradually revived, though she seemed very languid, and unable to fly. I returned her to the hive by the top orifice, and she was immediately pounced upon, hundreds of bees crowding around either to destroy or defend her. Next morning I found her surrounded in a cluster at the bottom of the hive. I took the cluster away and put it down on the green grass to examine more minutely their proceedings. The surface bees were excited and furious, anxious and eager to displace those beneath them, and to penetrate to the object of their concern, while those in the centre were motionless and quiescent; but there was no yielding of those beneath to either force or fury. Well, what am I to do? Shall I replace the cluster in the hive again, or shall I take a look of her hapless majesty once more, if only to see how far she has recovered from her exposure the night before, or rather how much more injured she would be by another night's encasement? The sun shone warmly out from a cloudless sky, as I began to unravel the mysterious knot. Slowly and carefully I proceeded to clear away the surrounding bees, till I came to the last few around the queen. Now is the critical time thought I, a rescue or a ruin; but so, too, thought my supposed inviolated queen, for by an effort as rapid as it was unlooked for, she freed herself of her remaining trammels, and bounded away like a shot through the blue serene, to my scarcely suppressed chagrin, and inconsolable grief. I looked around as bewildered, I dare say, as a schoolboy who sees some little winged favourite escape through his fingers, and soar away never to return.

In the other instances the evidence of encasement being caused by the entrance of stranger bees was of a still more con-

clusive character, I need not repeat details. In September I shifted some outlying hives, and drove others for a like purpose into my bee-house. The position of the shifted and driven hives was such as to cause little apprehension of many bees going astray. The exterior of the bee-house, however, was so unlike their former domiciles, that for two or three days afterwards the adjacent hives were a good deal disturbed by stray bees entering them. The result was the encasement of the queens of two hives.

Apiarians may accept it as a demonstrated fact, that not a few of the queen encasements which take place in an apiary where experiments and shiftings are constantly being carried on, are caused by the unwitting entrance of stranger bees. It is quite true, as Mr. Woodbury says, that there is an extraordinary commingling of bees in every apiary without any intermeddling with them whatever—thanks to the introduction of the Italian bee for this among some other discoveries—but it is not such stragglers as these that do mischief. Very young bees find their way, I have often noticed, into hives when returning from their first flight, and once entered there they continue to dwell. Hence a black hive in close proximity to a Ligurian, is sure to procure a considerable number of yellow-jackets to adorn its ranks. A young bee, it must be remembered, is rarely refused admittance; indeed, I have for a long time past been in the habit in early spring, when happening to have any weak hive in my apiary, of seizing some hundreds of young bees as they made their appearance for the first time on the stool of some strong stock, and transferring them to the weak colony before taking wing. These additions greatly benefit a weak stock. But besides these stray young bees being found located in other hives than their own, I also admit that adult bees sometimes fraternise with their neighbours in a similar way, but in neither case are these the bees that give rise to the turbulence and commotion of a queen encasement. It is only those that inadvertently by mistake, or forcibly from experiments, or shiftings, or some such cause, enter other hives, that become their pest and terror. Such stranger bees find themselves suddenly and unexpectedly in the midst of aliens, and are not prepared to offer, nor do they seek to receive, friendly overtures. They not only are disposed to dispute the occupancy of those they commingle with, but to look upon the queen which they meet as being as much an enemy as if they found her traversing their own hive, and hence the evil consequences which ensue.

There is a curious result which follows a queen encasement, which makes it doubly calamitous. I must repeat my conviction, now strengthened by further experience, that when a queen once passes through this ordeal of imprisonment, especially if long-continued, there is the utmost danger of her forfeiting all regard from her own subjects. A mutual jealousy seems to spring up, or rather suspicion on the part of the bees, and alarm on that of the queen. So much is this the case, that the bees appear to be carried away by a kind of wild delirium when they come into contact with her, and but for the invariable encasement which ensues, I believe so terrified does the queen become that she would escape from the hive altogether, if not thus prevented. And here I may be permitted to say that I prefer the term encasement as the best applicable to such phenomena, for I am unwilling to go the length of designating all the bees that thus imprison a queen as regicides, or would-be regicides. Additional light may yet be thrown upon this part of the subject, but in the meantime I am still of opinion that the encasement itself may be intended by Nature as the very means by which the commingling intruders and disturbers of the hive may be singled out and destroyed, the colony restored to peace, and the queen's own safety ultimately secured.

I am still more unwilling to believe, because opposed, I think, to the analogies of natural law and order, that bees are actuated by regicidal dispositions towards youthful queens which return from successful wedding flights. That they are encased under such circumstances is beyond a doubt. It is sufficiently attested by Mr. Woodbury, and also by Mr. T. B. Miner, of New York, who says that "young queens are generally found in a cluster like a hen's egg during the first few days of their inhabiting their new tenement, at the entrance of the hive, or near it;" but I can neither indorse the opinion of Mr. Woodbury, that this clustering around the queen can be characterised as a regicidal attack, nor that of his distinguished German correspondent, that the workers in such a case "treat her as a stranger." I would rather seek a solution, as I said before, upon principles more in accordance with the purposes and

objects of nature. Encasements of queens are assuredly not always regicidal. I observe that "A LANARKSHIRE BEE-KEEPER," in alluding to regicidal attacks, which he says, however, he never witnessed, adds, "But this I know, that I have seen queens imprisoned by their subjects when strange bees were admitted into their hives;" and I think a former correspondent, "INVESTIGATOR," held a somewhat similar opinion. I might here suggest the motive of the bees in clustering round youthful queens, which occurs at least with my own experience in the matter. I think the object may be to prevent the queen from again leaving the hive, to prevent further risks to her now more precious life, and to induce her to settle down to the maternal duties which Nature requires of her. I have seen a young queen on attempting to go abroad in such a case, seized by a couple of bees, which held her fast by the hind feet, and thus she was forced to return from outside the entrance, nibbled and followed after by several others. This queen commenced the work of oviposition shortly thereafter.

I now avail myself of this my first opportunity of returning my thanks to your valuable correspondent, "A RENFREWSHIRE BEE-KEEPER," for the kind offer which he made me through this Journal, in reference to foul brood. Did I think that my acceptance of that offer would lead to the well-meant objects he had in view, I should not have hesitated to put him to the trouble; but as the hive itself seemed to be beyond cure, I could not see that any practical good could otherwise arise by my acceptance. To others who have kindly sent me specimens of foul brood, and who have detailed their experiences in these columns, I also owe my thanks; and I may be allowed to hope that an evil, in whichever way originated, that has produced such desolating ravages as they detail, will, if not already, be speedily banished from their apiaries.—J. Lowe.

PLANTS POISONOUS TO DOMESTIC ANIMALS.

On last Saturday evening a flock of sheep (about forty), trespassing on the lawn here and ate a quantity of evergreen shrubs. During Sunday about twenty of them died, the rest of the flock seeming in a very precarious state. They ate a quantity of *Andromeda (Leucothoe) floribunda*; also, some Ivy, *Laurus-tinus*, Portugal Laurel, and *Rhododendron*. The veterinary surgeon who examined them thinks that the *Andromeda* is the shrub that has poisoned the sheep, as some of the blooms were found in the stomach of all that were opened.

If you will say which of the above shrubs would be the most likely to cause death to cattle eating them, you will greatly oblige. I may mention that there was no Yew that the sheep could get at. The veterinary surgeon says that there is no antidote known for the Yew poison, as it is not known how it acts on the cattle that eat it. I think that it would be very useful to a great many of your readers, if a list of all the plants that are known to be poisonous when eaten by cattle were published in your Journal.—W. G. M.

We have very little doubt that the *Andromeda*, or *Leucothoe floribunda*, as botanists now call it, was the cause of the sheep's death. *Andromeda ovalifolia* is fatal to goats if they eat it, and *A. polifolia* is similarly known to be fatal to sheep. They act as acrid narcotics. We think it probable that an infusion of nutgalls would operate as an antidote, as well as for the poison of the Yew and *Rhododendron*. The poison of the latter is so permanent that we have a record of a dinner whereat the guests were poisoned by a hare which had fed on the leaves of *Rhododendron ferrugineum*. We shall be obliged by the communication of any facts pointing out the poisonous effects of plants upon animals.—EHS.

POLLEN-GATHERING IN JANUARY.—The bees of the stock specially noticed in page 29 were seen to bring in pollen on the 5th, 14th, and 25th inst. A DEVONSHIRE BEE-KEEPER.

OUR LETTER BOX.

DISTINGUISHING COLOURED DORRINGS. *L. T. J. B.*—Silver-Grey Dorrings are birds of feather, and any deviation from rule is fatal. It is much easier to have them in than to cook. We will, therefore, describe the cock. Light almost white buckle and saddle, perfectly black breast and tail, white and steel-barred wings. The slightest deviation is a disqualification.

SILVER-SPANGLED HAMBURGERS. *W. M. H.*—You are a bit quite time your pullets, hatched in May, had, and if the dry weather lasts, they will do so within a fortnight. Snow and constant wet have upset many calculations of the sort.

SIZE OF PENS. *E. J.*—The larger your pens are the better. The best pens we had were those that were made and let by the late Mr. Cooke, of Colchester. You must be guided by the number of fowls to be shown, whether two or three. Turkeys and Geese require larger pens than fowls; Fantails require them of less size. Two adult fowls should have one 2 feet high, 2 feet in width in front, and 2 feet deep from front to back. It should be lower behind than in front. Smaller pens will do, but this size is desirable.

FEEDING OF EGGS. *Idem.*—It depends on the number of hens. If numerous you must wait some time, and even then be prepared for disappointment. If but three or four, you may set them after the hens have been with the cock three days. If you have many hens your best plan will be to run them with the cock for four or five days, three or four at a time, and to set only those eggs that have been laid by those birds.

FOWLS NOT WELL. *G. T.*—Your fowls will do better now. The weather has not been favourable for poultry.

ORFALM FOR FOWLS. *W. L. L.*—This can be obtained if any corn-dealer. Bruised oats are merely crushed by the machine used for preparing them for horse provender.

WHITEHAVEN POULTRY SHOW.—The first prize for Game pullets was won by John Robinson, Vale House, Garstang; and not by J. R. Robinson, Sunderland.

JEFFERSON SHOW.—The cup was given to John Thuckray, Petergate York, instead of Hull, as stated in the official prize list.

FOWLS, PIGEONS, AND RABBITS. *Look before you Leap.*—You may keep them together in the space you have. Spanish fowls and Rust Pigeons will be as good as any others.

ROBBERY COCK WHEEZING. *Alpha.*—Give him a dessert-spoonful of castor oil, and if needed another after two days. Let him also have bread soaked in ale once daily, and keep him out of the cold for a few days.

SHELL-LESS EGGS. *(King Brod and Buff Cocker).*—The soft eggs dropped by your Cochins-Chinas intimate that their egg-organs are over-excited. The food you give them is much too stimulating—Indian corn, barley, and ground oats. Omit the first-named entirely, and give the barley and oats on alternate days, and mashed potatoes instead of one feeding of corn daily. Give them a daily supply of lettuce leaves, and instead of crushed oyster-shells "now and then," have a heap of brick-bats' liny rubbish that they can visit whenever they please.

BOOK. *(J. Bennett).*—The price is 5s.

LIGURIAN BEES. *(A. R. C.)*—If the queens of your stocks are pure, they will remain so in the midst of any number of black bees. It is with young queens that deterioration commences, and in such a case as yours, we know of no better mode of proceeding than that recommended in reply to "M. S.," in page 455 of our last Volume.

BEE-STAND. *(I. Scherzhorn).*—No one that we know of manufactures bee-stands for sale. Any carpenter could make one. In "Bee-keeping for the Many," which you can have from our office free by post for five postage stamps, you will see drawings of the most simple and best stand.

ASPECT FOR HIVES.—REMOVING HIVES. *(Squab).*—We believe aspect to be of but secondary importance in bee-keeping, and if well sheltered from prevailing winds, should not object to hives facing the east. The best mode of removing bees a short distance is to subject them to an intermediate banishment of a few weeks to a distance of—say a mile and a half. If moved direct, it is best done towards the end of a long frost, as bees after a certain period of confinement seem in some measure to forget the original position of their home, and adopt a new situation with more facility than at other times. Another mode of overcoming this difficulty was described by "B. S.," in page 204, of our last Volume. A verandah or any similar erection against a wall, of sufficient width to admit of passing behind the hives, is the best kind of bee-house that we are acquainted with. We ourselves have no bee-house whatever, but protect both hives and supers with hive-roofs and outer cases as described and delineated in pages 17 and 18 of the fifth edition of "Bee-keeping for the Many."

BUTTER NOT YELLOW IN WINTER. *(W. S.)*—We need hardly say that the only legitimate way to obtain sweet butter of a good yellow colour, is to let the cows have fresh green food, but as this cannot always be done in winter, artificial means are resorted to, and one of the most innocuous of those used is the juice of carrots, which after being grated are squeezed through muslin or something of the kind, and the juice added to the butter after the last washing. Very little will suffice. It is not by any means advisable to add too much of this colouring matter, as at the best it gives but a dead yellow colour; a little, however, improves the appearance, and we could never discover the least taste of carrot in the butter. A larger quantity of carrots is sometimes put into the cheese, the effect being the same, only the buttermilk is coloured also. We have known some chemical substance used instead, but would not recommend it; neither would we advise much of the carrots, except in cases where the eye has to be pleased instead of the palate. No management on the part of the dairymaid can make butter yellow in winter, when cows are fed on dry hay alone. The only means available is to stain the cream or the butter in some way, and some secrecy is often enough maintained about the adulteration. Of course, all cream is not alike, and the food of the cows gives certain properties to the milk and cream which no management on the part of the dairymaid can entirely alter. She may, it is true, spin good cream, but feeding cows on cabbage, turnips, and the like imparts a flavour to butter not easily got rid of, or where it is, the result is by no means a good article.

POULTRY MARKET.—JANUARY 29.

We have but a moderate supply of everything, with an average demand and fair prices.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 45.2°; and its night temperature 31.1°. The greatest heat was 65°, on the 10th, 1831; and the lowest cold 19°, on the 5th, 1830. The greatest fall of rain was 0.67 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

ORCHID GROWING IN LONDON.

ALTHOUGH to talk of growing Orchids in London may seem to many persons, even those most conversant with their habits, rather utopian, I hope to be able to show

that it is not only possible to cultivate these lovely flowers in the heart of our great city, but that, with care, many of them may be flowered as well in London as elsewhere; and it is with the hope that others may take up this interesting subject that I am tempted to record my own experience in the matter, slight though it may be.

Some time ago circumstances compelled me to reside in London for the greater part of two years, and as it was impossible for me to live, even there, without flowers, I determined to try my hand at cultivating some of my favourites. Of course I was laughed at by my botanical friends. I was told that I should never succeed; it was impossible to do so; it was waste of time, with many like encouraging remarks, but I had made up my mind to try; I had seen Wardian cases with plants thriving in them, even in London, and I felt convinced that I should succeed.

But what sort of plants was I to grow? for I soon found that very few flowers long continue in health even in Wardian cases, and in the part of the town where I was residing nothing would thrive without some such protection. Here was a difficulty, but on mentioning it to a friend, he said, "Why do you not try your favourite Orchids?" I had two in a small case in my office in Great Tower Street, which lived and grew for a long time." The hint was not thrown away upon me, and I soon found the truth of what he said; for certainly, excepting Ferns, Orchids seemed to thrive better in a heated Wardian case which I had than anything else, and as I have always had a passionate love for these beautiful flowers, and had been very successful with them in the country, I resolved to devote my spare time to their culture, and see what could be done.

The first matter to be considered was, where to grow them. In Wardian cases, though they lived and grew a little, they did not thrive to my satisfaction; besides, I could not have a case large enough to hold many in my window, nor was there sufficient light and air in a room. I therefore determined to try some other plan, and after turning it over in my mind, I fixed upon the following:—Outside my sitting-room window was a flat space, covered with lead, which formed the top of the doorway, it was 6 feet by 3, surrounded by a low wall, 8 inches high, of brick and cement work on three sides, the house and window forming the fourth. This place I fixed upon as a

favourable one on which to erect a sort of large Wardian case, or small greenhouse, and my window being large, reaching nearly to the ground, I could pass through it when needful into the miniature house. When finished it resembled a small lean-to bothouse, 6 feet long, 3 feet wide, 6 feet high at the window, sloping to 2 feet in front. It was heated by hot water from a small boiler in the sitting-room fireplace, which worked uncommonly well. The following sketch will explain more fully my meaning.

- a The case, 6 feet long by 3 feet wide.
- b Window of sitting-room.
- c A glass door, with 6 inches between it and the window, in order to prevent the sun finding its way into the room.
- d, d' Ventilators.
- e Body of the case, 6 inches deep, filled with sand, the bottom being well drained.
- f, f' Hot-water pipes.

caution I found it did not do to give much air in the day-time, the air then, do what you pleased to it, being impregnated with deleterious matters which told in time on the Orchids, so that I always contrived to give air by night, when it is purer, particularly towards early morning before fires are begun to be lighted. I believe this to be a vital point in growing Orchids in London. Still, the great point after all is to grow only those plants which require the least air, and this I soon found by experience; some Orchids, such as the Cattleyas, Lælias, Odontoglossums, &c. never doing well in town; while others, such as the Aerides, Dendrobiums, Stanhopeas, Vandas, &c. with plenty of heat and moisture, thriving as well there as anywhere, and flowering profusely. Their treatment was much the same as that which they received in the country Orchid-houses, excepting that they were made to do with as little air as possible.

The temperature of the house was, in spring and summer, by day 85°, by night 70°; late in autumn and in winter, 65°

by day, and 60° by night. This was without sun heat; with the sun the temperature was allowed to rise several degrees, but then the house only received the morning and evening sunlight. During the spring and summer months the house was kept very moist, the sand, pipes, &c., being often watered, but I generally contrived to have the plants nearly, if not quite, dry once in twenty-four hours. If there was too much steam it was let out by the top ventilator, but this was rarely necessary. In winter, of course, the case was kept drier.

I purpose including this paper with the names and descriptions of a few sorts which I found by experience to thrive well under such circumstances, and which I have myself successfully grown in London. There are, beyond a doubt, very many others which will do equally well, but which have yet to be tried.

AERIDES CRISPUM and **VINDUS** are both excellent plants for a London Orchid house, although most of the *Aerides* will thrive there. *A. crispum* and *A. virens*, however, grow and flower well without much air. The blossoms of the former are white, tipped with pink, and are abundantly produced in July and August. Those of the latter are of a lovely peach colour, and appear from April to June. They both succeed best grown in pots.

ARANISIA PULCHERRIMA.—A dwarf plant with pretty white and yellow flowers, produced at different times of the year. Succeeds best in a pot.

BRASSAVOLA AUREA.—A Rush-like plant with large white flowers. It generally blossoms in September or October. Requires to be grown on a block.

BROGHIDIA SANGUINEA.—A lovely evergreen Orchid, with beautiful spikes of crimson flowers, produced freely during the summer. It requires to be grown on a block, with a little moss round the roots.

CALANTHE VESTITA (*VERBOCULATA*).—Rather a large plant for a case, but one which grows well. It produces its delicate flowers on long spikes during the winter months; they are white, with a blotch of red on the lip. It is best grown in a pot.

CAMAROTIS PUBERULA.—A most lovely Orchid with rose-coloured flowers, freely produced from March till June. It thrives best grown in a basket, and requires plenty of heat and moisture.

CYLOPUS CRISTATUS.—A splendid dwarf Orchid, with flowers 4 inches across. It thrives well in London, and blossoms in the early spring. Pot culture.

DENDROBIUMS.—Many of the *Dendrobium* tribe thrive well, although some are rather shy of flowering. *D. formosum*, *D. Lowii*, and *D. pulchellum* are very good ones for the purpose, but *D. Jenkinsii* is the best. It is a dwarf plant, with beautiful buff flowers, most freely produced one or two at a time. It requires a small block on which to grow it, without any moss, and the plant should be hung up close to the glass.

HUTTENIA MARINATA.—A pretty evergreen Orchid, flowering constantly; the blossoms are pink, purple, and white. It should be grown in a pot.

LIPARIS COMPLANATA.—A really beautiful little plant, with rose-coloured blossoms produced at different times of the year. Thrives uncommonly well in a confined case. It should be grown on a bare block of oak wood.

PLEUROPSIS.—No Orchid thrives better in London than this noble plant; unfortunately, its size is against it. It flowers with me well, and its beautiful blossoms, bearing such a wonderful resemblance to a dove, were always greatly admired.

PLEUROPSIS AUREA and **GRYPHOPSIS** are so well known that any description is unnecessary. They thrive and flower well, particularly *P. aurea*. They should be grown on blocks of wood.

SARCOCHILUS (*CRISTATUS* and *MINOR*), both excellent plants for a London Orchid house. The former is a small plant, without any long flowers freely produced in May and June, the latter is equally small, with spikes of red flowers produced in February, March, and April. Both should be grown on small blocks without moss.

SCHIZOCALYPSA.—A noble Orchid, with large crimson and purple flowers, nearly 7 inches in diameter. Blossoms during summer. Pot-culture suits it best.

SCHIZOCALYPSA CRISTATA.—One of the best, if not the very best, for a London Orchid house. The blossoms are of a lovely saffron colour, produced during the winter months, and lasting long in beauty. It should be grown on a block.

SCHIZOCALYPSA.—Many of these curious and beautiful flowers thrive very well in a case, particularly *S. aurea*, *S. insignis*,

and *S. tigrina*. They should be grown in shallow baskets, as the blossoms generally push their way out through the bottom. They are very curious-looking, and make a good variety.

VANDA STAVIS.—A noble plant, grows well and flowers profusely in a case. The blossoms are large, of a beautiful white, spotted with crimson. Either basket or pot-culture will suit it.—J. H.

MANGOSTEEN CULTURE.

HAVING been applied to for advice and further instructions, by several persons who happen to possess small plants of the Mangosteen, but who complain that they have no house of a sufficiently high temperature in which to grow them, I thought it might be as well to say a few words on the subject through the medium of your valuable Journal.

All who are fortunate enough to possess well-established plants should at once commence starting them into growth. For this purpose, if there is no stove where they can be kept very hot and close, a hotbed may be made up of good stable dung, and the plants put under a frame, keeping them close to the glass. It is important that the dung should have been thoroughly turned and mixed, and it should have lain in a heap for some time previous to being used. The bed should be made 5 feet high, first taking the precaution of having it well drained underneath, and, when it is a little settled, the frame may be put on, and the dung covered 6 inches deep with sand. As soon as the furious heat is over, the Mangosteen trees may be put in, taking care to ventilate freely at first; if the heat is too much the pots should not be plunged until all fear of burning is over. The top temperature may range from 80 to 90°, and the bottom heat from 5° to 10° higher. The trees must be kept moist and close, giving little air, and keeping up the heat by linings. They will soon begin to grow freely, and they must be kept growing *without a check* all the summer, for if once checked, though but for a few hours, the chances are ten to one against their restarting, and thus a season may be lost. Should flower-buds appear the first summer they must be carefully picked off; this will materially strengthen the trees, and cause them to throw out fine strong shoots.

The grand secret in growing the Mangosteen is to keep the trees growing vigorously, and, if this is done, sooner or later they will flower and fruit—it is only a question of time; whereas, if they are grown in an ordinary stove temperature, they will live, and even grow slowly, but never bloom. This I have repeatedly proved by experiment, and I am certain that all the failures one hears of arise from this one cause. I do not hesitate to say that the Mangosteen may be fruited as easily as any other tropical fruit, but then it must have every ray of light our skies afford. It must be grown rapidly under a high temperature, have plenty of water and weak liquid manure, and not too much air.

Unless the Mangosteen is in a very vigorous state of growth it will never show bloom.—J. H.

We think it due to our readers, as well as to "J. H.," to state that he cannot send plants to anyone of the Mangosteen, which he has received from Java and Madras—they are very expensive. See advertisement.—Ebs.

POINSETTIA PULCHERRIMA CULTURE.

At page 160 of your last Volume I note some excellent remarks on the cultivation of the Poinsettia from your correspondent Mr. Edwards, and to which I wish to add a few observations derived from my own experience. This interesting and important winter-flowering plant is capable of a much greater degree of perfection than is generally known. My mode of treatment differs somewhat from that recommended by Mr. Edwards, and is as follows:—

After the plants have had six weeks' or two months' rest by withholding moisture, I cut them back to within half an inch of the old wood, keeping them in the stove until they have started into growth. About the beginning of May they are shaken out, potted into smaller pots, and placed in a cold frame as near the glass as possible, keeping them close for a few days, when air is gradually and cautiously admitted. After they have filled the pots with roots they are repotted into their flowering-pots, which are from 6 to 8 inches in diameter, and as the warm days advance the frame is slightly raised by a brick under each corner, keeping the lights off excepting when

the sun is very hot, and syringing overhead in the evenings of hot days, but avoiding saturating the ball, as they are impatient of too much wet, at the same time they should never be allowed to flag. In July they are stopped, and they are continued in the cold frame until October, when they are removed into a stove with a temperature of from 65° to 70°. About the middle of November they show flower, and, if duly attended to, they will continue to bloom in perfection until the middle of February. By the mode of treatment just described I have at the present time, January 24th, plants varying from 6 to 30 inches in height, with flower-heads measuring from 12 to 14 inches across.—JAMES LANE, *Manchester*.

THE GLADIOLUS.

I HAVE no hesitation in saying that both in Scotland and Ireland horticulturists are far in advance of us in England in the attention that they have given to this beautiful autumnal flower, and in the extent of its cultivation, as well as the encouragement afforded to it as an exhibition plant. As the present is a favourable season for obtaining bulbs, it may, perhaps, give an impetus to its cultivation, and be a help to some of your readers, if I give a few notes concerning it, which a tolerably long acquaintance with it somewhat entitles me to do.

That the cause of the non-cultivation of the Gladiolus in the south of England arises from the losses that growers have experienced I have no doubt. Some few years ago a disease of great virulence, and in some places of most destructive character, manifested itself amongst their collections; I knew one that cost nearly £100 that was almost destroyed, and others so materially diminished that the growers lost all heart and abandoned them; and that this disease still exists I have had proof again this year. Personally I have never suffered severely from it. Gaps have been always more or less found in my beds, but nothing to deter me. I am inclined to think that a good deal arises from the non-drying of the bulbs, although, as in the Potato disease, one can really say very little about it. On taking up my bulbs this year I found some of them marked with black spots, apparently indicative of disease. Now, these bulbs I shall put into a nursery, and on no account admit amongst my others. My own opinion is, that although they may push both stems and roots (and some of them seem inclined to do that already), yet that they will eventually rot. Some of them that were worse than others I have already noticed to gradually become more and more black, and they will have to be thrown away. High cultivation may have something to do with it; and although I think the idea with which some started—that the poorer the soil the better it was suited for the Gladiolus, was a mistake, yet I should be careful not to introduce fresh manure into the beds at the time of planting. Let the beds be well manured in the autumn; perhaps, indeed, if the time would allow of it, it would be better to lay the manure 6 inches below the surface, as is done by Kammebus growers, and then not to put any manure into the bed itself. Besides this, I should be careful to lay each bulb in a bed of white sand when planted, and to cover it with it before again raking over the soil. This may seem an unnecessary trouble; but as the Gladiolus is a florists' flower, and as the new varieties "come out" at 8s. and 10s. a-piece it is surely worth the trouble.

The Gladiolus requires little management in the after-growth. Should the season be a very dry one it will be well to water the beds, but in ordinary seasons this will not be necessary. One difficulty has always been to keep the beds in good order when the flower-stems attain any length, as they are then so apt to fall about. To stake each is not possible, and would, besides, make the bed look very stiff. The plan adopted by my friend Mr. Lombard, of Dublin ("Autis"), is one which I followed last year—namely, to obtain narrow strips of the border of druzget as it is torn off before being made up, then to drive posts into the ground at each row, nail the druzget to these, and then weave it in and out amongst the stems. In a row containing forty bulbs I have four of these stakes, and sometimes when a stem is very tall I also affix a smaller stick to it. There are three rows of this druzget, and by this means all the stems are kept in their place, while the softness of the material prevents it from rubbing the stems. There must be, of course, two strips so as to enclose the stem in a sort of loop.

In putting up stands for exhibition there is a great variety

of methods adopted. I think myself that the holes should not be behind one another, but in quincunx fashion, as then one bloom would not hide the other; and that either no foliage should be permitted, or else only a leaf or two of the plant itself; but perhaps the former plan would be preferable. I would expressly prohibit their being shown in separate pots, in ginger-beer bottles, in Hyacinth-glasses, or anything of the kind, and neatness should certainly be the order of the day. The plan adopted by Messrs. Dickson, of Newtownards in Ireland, the best growers, or at any rate the best exhibitors, in that country, is to place wire at the back of each row and tie the stem to it. The wire, painted green, is hardly noticeable, and each is kept in its place.

So far as to cultivation, and now as to varieties. Their name is legion, but a great many are utterly unworthy of a place in a bed. Years ago they might have done very well; but the progress has been so great, that it would be as great folly to grow such flowers as Agäte, Helène, Daphne, and others, as it would be to grow the Fuchsias of a dozen years ago. There are two sources whence new varieties have been obtained—France and Ascot, the former mainly consisting of the flowers of M. Souchet, the latter of Mr. Standish exclusively. Other growers are now raising seedlings, and I dare say by-and-by we shall find many of them in our catalogues. My friend Mr. Lombard speaks very favourably of some of his, and my neighbour and friend, Mr. Sladden, of Ash, has also some excellent varieties. I shall give a list of such fresh ones as I know to be good, referring my readers to the catalogues, French and English, for the descriptions, marking at the same time with an asterisk the very best bright-coloured flowers, and with an obelisk the best of the lighter and more fancy varieties

*Achille	*Linnæ
Belle Gabrielle	Madame de Sévigné
Berthe Rabourdin	*Madame Furtado
Canari	Madame E. Verdier
+Charles Dickens	Madame Pereire
Cherubim	Madame Rabourdin
*Comte de Morny	*Madame Vilmorin
Decandolle	Marie Dumortier
+Dr. Lindley	*Meyerbeer
*Due de Malakoff	*M. Lebrun d'Alban
+Edulia	+Peter Lawson
El Dorado	+Pline
Endymion	*Prince of Wales
+Flore	*Princess of Wales
*Fulton	+Reine Victoria
+Imperatrice Eugénie	Raphael
*James Carter	Rubens
*James Veitch	*Stephenson
James Watt	+Stuart Low
John Bull	+Walter Scott
+Le Poussin	

I say nothing of the new varieties, against which we must write "not proven" as yet. Mr. Standish has raised a large number of fine seedlings; but instead of waiting till he has had a stock of each, he has let them out when he has had a few bulbs, consequently it is very difficult to obtain them. Save in his own catalogue I have only seen one, Messrs. Barr and Sngden's, in which any of them appear. Amongst the best are—

*Samuel Weymouth	Beauty of Bagshot
*Eleanor Norman	*Lord Clyde
*Dr. Hogg	*Joseph Meston
*Mrs. Dombraïn	Viola
*Miss Howell	Mrs. E. Nott
Scottish Chief	*Sir James Clark
J. W. Lane	Lucy Neal
*Norma	Lucifer

I have marked with an asterisk those that I consider very good; but Mr. Standish's catalogue contains a large number, from which a good collection can very easily be selected. It is very much to be desired that the number of amateurs should increase. There ought to be a much larger display at the autumn Show of the Crystal Palace than there is. I can bear witness to the interest that they excite amongst the visitors.—D., *Deal*.

DEATH OF MR. MAJOR.—It is with regret that we have to record the death of Joshua Major, Esq., landscape gardener, of Knowsthorpe, near Leeds. The deceased gentleman held a prominent position in his profession, and was the author of several valuable works. In 1829 he published a work entitled, "A Treatise on Insects Most Prevalent on Fruit Trees;" in 1852, "The Theory and Practice of Landscape Gardening," an important work, which met with high and deserved encomiums from the public press; and in 1861, with the assistance of his son, who succeeds him, "The Ladies' Assistant in the

Formation of their Flower Gardens," a work designed expressly to meet the prevailing taste for the bedding-out or grouping style. He was also a frequent contributor to the "Gardener's Magazine," under the conductorship of that eminent man, Mr. J. C. Loudon, who highly appreciated his plans and papers on landscape gardening and other subjects. He delighted in works of philanthropy. He assisted in the formation of the first Sunday school in Leeds, of which he was superintendent for many years; and all religious and charitable institutions he took great interest in and actively promoted. His personal qualities were of a high order. He was of a cheerful disposition, simple in his tastes and habits, and impressed all who had the good fortune to know him as being a thoroughly kind-hearted and estimable man. He was highly appreciated by his workmen; and as an evidence of this, six of them served him fifty, forty-two, forty, thirty-two, twenty-nine, and twenty years respectively. After upwards of half a century devoted to his profession with an ardour and perseverance rarely equalled, he died on the 26th of January, at the advanced age of seventy-nine years.

ROSES.

I THANK Mr. Robson for his appreciation of my Rose articles. I agree with him that Roses on their own roots, in suitable soil, highly cultivated, and well watered, succeed well. Still, Roses are volatile flowers, and one cannot predicate a universal of them. Some that will not do well on any stock will succeed very well on their own roots, and *vice versa*. The character of the soil and of the summer affects some. Roses on their own roots, and also on the briar, require better soil than those on the Manetti; they also need more manure and more water. On their own roots, when well established with firm roots, they will withstand more severe weather than those on the briar or Manetti. They have this advantage also, that if the wood of the current year is injured by the wind beating off the foliage (the lungs), or by blights or fungoid diseases, you may in the year following cut them down close to the ground.

Mr. Robson says that Roses on their own roots are not so affected by aphides as the Manetti or briar Roses. Probably this arises from their slower and less succulent growth. Both fungi and aphides take hold of the young foliicles, which, in Roses on their own roots, may be of a less succulent or less tempting character. I find here that Roses on the briar are not so fine as Roses grown on the Manetti. I have comparatively few on their own roots to draw a comparison by. I have fine plants of Souvenir de Malmaison on their own roots and also on Manetti. I see no difference between them. I have also a number of plants of Triomphe de Rennes—a most first-rate Rose, which is never out of bloom here, and never has a blind end—on its own roots, on the briar, and on Manetti. I cannot tell which is best.

I observe that Mr. Robson prunes in winter. I have for an experiment pruned this winter, beginning at Christmas, every Rose here. I have just finished. This may be too early; but I am satisfied that, in order to meet the shows, which are far too late for a well-managed rosery, we cut them back too late. Properly speaking, the time to cut them is when the eyes look full and fresh. It is true, the spring frosts may cut off the first shoot; but that matters not, as there are usually two other eyes more or less dormant. These will start later and synchronously, and one of them may be cut off. Usually from the 10th to the 15th of March is the time to cut back Perpetuals. Teas want but little cutting, and should be cut later. Hybrid Chinas and summer Roses may be cut back in February. Tea-scented Noisettes against south walls may be cut back earlier than any of them, if blooms are desired in May. I want not the Yellow Banksian, Solfaterra, Gloire de Dijon, Triomphe de Rennes, and Celine Forestier—four admirable yellow roses—begin here in May, and never stop till winter is severe. They are hardier than Teas, and bear a greater profusion of bloom. I have put Gloire de Dijon and Triomphe de Rennes among the Tea-scented Noisettes, because they appear to belong to that class. M. E. Verdier puts the former among the Noisettes, and the latter among the Teas.

With regard to Manetti suckers, it is the fault of the planter. Briar suckers give great trouble here, but I hardly know what Manetti suckers are. They rarely come from the roots, and rarely from the stock after the first year. It is seldom that they spring from that here. The way to plant them is as

follows: Open your trenches, and put rotten dung along the line; put in a little earth on that, then put the plant on it, and cover with earth and dung alternately, treading it in hard, and close against the stock, till you have risen 2 or 3 inches above the point of union. By the exclusion of the air the eyes in the stock will die. By planting the Manetti stock above ground, or by admitting air, you will have a "furze baulk" of Manetti instead of Rose wood. It is the easiest managed and least troublesome stock in the world. Before planting Manetti Roses look over the stock, and cut out such eyes as you see.

This leads me to Mr. Robson's particular request in the last paragraph of his article with regard to Tea Roses on their own roots. Mine is not Tea Rose land, nor is the place adapted for them. I know but little about them. Tea Roses out of doors are out of bounds. The truest grower here is Sombreuil on its own roots. I have no healthier or harder Rose at this place. It never blights, and carries its foliage in the most severe winters. I have it good also on the two other stocks. Elise Sauvage is good on the Manetti; a strong plant on its own roots has died. I have these good on Manetti—Adam, Rubens, and Elise Varbon. I have of Devonian-is several plants, good on their own roots. La Boule d'Or is very good on the Manetti, and is one of the hardiest. It produced at one time in summer twenty-three blooms, which opened well. It also bloomed well in September. Usually it is a hard opener. I have only one other Tea Rose, the gift of Mr. Hollingworth—La Sylphide; it is on its own roots and does well. I have no doubt that if you take the whole body of Teas, and mean to keep them permanently out of doors, that it is best to have them on their own roots, taking great care of their roots for a winter or so. After that, unless in the case of such delicate Roses as Elise Sauvage, you need not fear the winter more for them than for any other Roses. If their wood is injured you can cut them to the stump, and they will be the better of it. Mr. Hollingworth, of Turkey Mills, Maidstone, would be better able than I am to speak on this matter.—W. F. RANLYFFE, *Tarrant Rushton*.

THE MODERN PEACH-PRUNER.—No. 21.

VARIATIONS OF PEACHES AND NECTARINES FROM SEED.

(From the Fruit Record of Sawbridgeworth.)

THE great increase in the number of varieties of the Peach and Nectarine which are now cultivated is due to the introduction of orchard-houses. By these means a long succession of fruit is obtained. Very early and late sorts thus matured are of immense advantage. Of course, with the increased number of sorts the difficulty of proper selection keeps pace. It is, therefore, necessary to add a list of choice kinds. The Peach-fancier, however, can now raise varieties from seed for himself, and by judicious fertilising obtain new sorts, the fruiting of which will at least be a source of infinite pleasure. Having myself experienced this satisfaction, and successfully fruited some fine Georgian varieties (such as Esquisse, Golden Purple, Canary, Thomas's Late, Baldwin's Late, and Stump-the-World), besides holding a number of fine seedlings as yet unfruited here, it occurred to me to obtain further information on this interesting point; and the answer of Mr. Rivers is as follows:—

"The seedlings of 1865 were about two hundred in number. Their qualities and deviations from the parent stock have been accurately noted down. They are numbered for reference, and dates of ripening added.

"No. 1. August 10th. An orange Nectarine from Fairchild's Early. Liable to crack.

"No. 2. August 10th. A seedling from Early York, but having leaves with glands, and thus not liable to mildew. Flowers large, like the parent, and the only one out of twenty which deviated from the parent stock.

"No. 3. Oct. 1st. A seedling from a yellow clingstone. Small but rich, with large flowers.

"No. 4. Sept. 20th. A very large clingstone from Early York, in the third generation. This is a remarkable variation, with the large flowers of the race.

"No. 5. Sept. 4th. A Peach raised from the Balgowan Nectarine. Small, rich, with small flowers.

"No. 6. August 16th. A large Peach from Pêche Bonnaux. Of a delicate cream colour, slightly tinted with red under the skin; firm flesh, and delicious aroma. The parent I found in a small nursery in Brittany as a robust standard. This remarkable Peach has been since named Dr. Hogg, and is first-rate.

"No. 7. August 18th. A large and deep crimson seedling from Belle Bausse, differing from it in its flowers. Called the Crimson Mignonne.

"No. 8. August 20th. A very large pale Peach raised from a white Nectarine, itself from the New White Nectarine, so that this Peach is the third generation from a Nectarine. Flowers small.

"No. 9. August 10th. A large early seedling from Early Albert, which was raised from an early Belgian Peach called Montagne précoce. A very valuable early Peach, called by the Fruit Committee the Dagnar Peach. Flowers small.

"No. 10. Sept. 18th. A Peach raised from that large sort, Pavie de Pompone, and small, with its rind of a pale straw colour, without the least red tinge. I mention this to show the great diversity of character often originating from the same stock, as will be seen presently. Exquisitely sweet. Flowers small.

"No. 11. A large pale yellow seedling from Royal George. Flesh remarkably juicy like its parent, and totally unlike the yellow American and south of Europe Peaches. It has none of the Apricot flavour. Called the Golden Royal George. Flowers small.

"No. 12. August 12th. A medium-sized melting Peach, seedling from Hunt's Tawny Nectarine. Named by the Committee the Early Alfred Peach.

"No. 13. Sept. 30th. A very large cream-coloured clingstone from American Heath-ling. I mention this clingstone, passing over many others, as being, unlike its parent stock, very juicy. Flowers small.

"No. 14. August 10th. The Early Silver Peach, the first generation from the New White Nectarine. One of the most beautiful Peaches. Skin pale silver, pink-tinted. It is the parent of many seedlings, all of high character.

"No. 15. Sept. 8th. A large late Nectarine from the Elruge, with the Stanwick flavour. It is most curious to note the influence of the Stanwick on the flavour of seedlings, as if the pollen of this peculiar sort had effected a radical change in their character, reminding one of the introduction of the Black Cap Raspberry from America, which has stained all our autumn Raspberries. Flowers small.

"No. 16. August 28th. A large orange Nectarine originating from Hardwicke Seedling, which is of a totally different character, and itself also differing from its parent the Elruge. Flowers large.

"No. 17. August 26th. A large green Nectarine, a free-stone, raised from the Roman, which is a clingstone. The flavour is much influenced by the Stanwick cross.

"No. 18. A large seedling Peach from the Noblesse. Much like its parent in texture, but, unlike it, has glands, and thus not liable to mildew, which all the glandless Peaches are. To keep it in its class it is called the Alexandra Noblesse. Flowers large.

"No. 19. July 11th. A remarkably early seedling Peach, pale, red-tinted, medium size, melting, and juicy. Raised from a Nectarine a seedling from New White (the Early Silver Nectarine). This Peach is, therefore, the third generation from the New White Nectarine. This is a remarkable deviation in every way.

"No. 20. July 14th. A medium-sized Peach, marbled with bright red, juicy, and rich. Raised from Early Albert, and likely to be of great value as an early sort.

"No. 21. July 14th. A large pale Peach like the Noblesse, melting, and juicy. Raised from Early Silver, and the third generation from New White Nectarine. Decidedly the finest large early Peach known, and with the two preceding, being ripe in July (three weeks before the Early York), likely to be of great value; and probably in Guernsey with skill might be ready by the end of June, when only forced Peaches are to be met with. Called the Early Rivers Peach. Flowers large.

"No. 22. Sept. 20th. A Peach, measuring 12 inches round, pale straw, rosy cheek, firm yet juicy flesh, and rich aroma. Raised from Princess of Wales, and so third generation from Pavie de Pompone. One fruit was ripe, and submitted to the Fruit Committee at South Kensington, and it received a first-class certificate. Named Lord Palmerston. Flowers large.

"No. 23. Sept. 20th. A large melting Peach. Skin beautifully marbled; flesh pale yellow, juicy, and excellent. Raised from Pine Apple Nectarine, and the third generation from the Pitmaston Orange. A remarkable variation. Its parent and grand-parent produce the most beautiful, large, bright flowers of all. This has given us small flowers.

"No. 24. Sept. 6th. A medium-sized Peach, with a bright

red cheek. Raised from Hardwicke Seedling Nectarine. The parent has large flowers, but this one has them small.

"No. 25. Sept. 6th. A Nectarine of the largest size, juicy and rich. Raised from Prince of Wales Nectarine, itself a seedling from a Peach. Earlier and much larger. Flowers small.

"These extracts from my Fruit Record show the extraordinary changes wrought by cross-breeding, either by accidental fertilisation by insects, or, as it seems to me, by 'breeding in-and-in'—i. e., by selecting varieties generation after generation, and thus conveying the peculiar qualities appertaining to a race. Seedling No. 22 is an illustration of this. In making my collection of every kind of Peach known in Europe and America, I some years since received that largest of all Peaches, Pavie de Pompone. Owing to its great size and to its beautiful Rose-like flowers I always felt much interest in it, but its fruit was seldom fit to eat. It was not till 1857 that I thought of raising seedlings from it, for I had slight hopes of raising a melting Peach from a clingstone. I planted, however, some stones; one tree grew, and produced melting Peaches, rather late, but of good quality. It was named the Princess of Wales. This variety has much of the robust habit of its parent, and gives the same grand flowers. The seedling raised from this departed widely from the parent stock, producing small flowers and melting fruit, but not large. In 1862 stones of the Princess of Wales Peach were planted, one of which produced fruit in 1865. This seedling gives fruit firm like its original ancestor, though a melting Peach. This is a case of adherence to race.

"In 1815 the late Mr. Williams, of Pitmaston, planted stones of the Elruge, which has a white flesh and small flowers, and one of these produced a tree which gave large beautiful flowers, and was called the Pitmaston Orange Nectarine. It was the first full-sized orange Nectarine known in England. I planted stones of this sort in 1856, which, in due time, bore fruit nearly all identical with the parent. One, however, large and ten days later, I named the Pine Apple Nectarine, owing to its flesh being transparent like the Pine. In 1862 I planted stones of this sort, but the young trees gave slight hopes of deviation. In 1865 several bore fruit, all like their grand-parent the Pitmaston Orange Nectarine, and were laid aside, till one day my attention was drawn to two very beautiful Peaches hanging on one of the trees. Here we have the fourth generation of the Elruge Nectarine, and it proves to be a large and late Peach.

"I may add that till I had bought my experience of the great variation in seedlings I could never believe in the origin of the Pitmaston Orange Nectarine. I was, perhaps, more inclined to think so from having received from the south of France, many years ago, a full-sized orange Nectarine under the name of Brignon Musqué. This gave large beautiful flowers, but was a clingstone.

"I may here mention that, as yet, Apricots have not given the remarkable variations shown by Peaches and Nectarines. —THOS. RIVERS."

It will be seen from the foregoing how short a time it requires to test any new variety. Parents having very distinctive qualities should be selected to experimental use with, and a short experience will be the best of all teachers. Other numbers might be added on the best shapes for orchard-houses and their general management, as also on the temperatures adapted to them, &c., but such topics, besides being beyond the limits fixed for the work, are also extraneous to the leading purpose, which was—the training and pruning of the Peach according to the latest experience.—T. C. BRÉHAUT.

LIME AND SULPHUR MIXTURE FOR THE DESTRUCTION OF RED SPIDER AND MILDEW.

I AM induced to send this, as amongst the numerous communications which have of late appeared in the Journal on the above subject this remedy has not been named that I am aware of. The mixture I make as follows:—1 lb. of quick lime and 1 lb. of flowers of sulphur well mixed together in one gallon of water, boiled about half an hour, and stirred at intervals whilst boiling. When it is quite cold the clear liquid is poured into bottles, and in this state kept for use.

About a quarter of a pint of the liquid to four gallons of water, and stirred until the whole becomes of a pale yellow, I have generally found sufficiently strong for use; but half as strong again will do no harm.

In the case of mildewed Vines I apply it early in the morning by drenching them well with the syringe; but for red spider I close the house rather early in the afternoon and then apply the syringe; of course it is better to keep clear of the bunches as much as possible, but it does not disfigure them. In a late house of Black Hamburgs, so treated last summer, no one could see any trace of it except by close scrutiny. With regard to Peach trees, I generally apply it in the evening. For mildew it may be necessary to use it a second or third time; but for red spider I find that twice in the season is quite sufficient. For Cucumbers, after well syringing the plants, I keep the frame or pit close for a few days, throwing a mat over the glass when the sun strikes it, instead of giving air.

This mixture must not be used for Melons, as it will certainly destroy the plants. I have no doubt that it will be found of great service amongst other plants when affected either with mildew or red spider; but as yet my experiments have gone no further than what I have stated above, and the loss of two crops of Melons has warned me to use it with caution on plants not hitherto tried with it. White paint is discoloured by it, but only for a time.

In conclusion, I assure your correspondents, Mr. Wills and "T. S. W.," that if, on the first appearance of red spider on the Vines, they will do as I have stated above they will not find it necessary in future to paint the stems of the Vines as a preventive of that arch-enemy.—J. M., *Ermouth*.

ICE MACHINE.

AFTER THE SNOW on the 10th of January, a frost of 15 occurred on the following night, and on the Friday we were lucky in being able to fill our ice-house, as Saturday brought a rapid thaw. I have thought for some years, that if ice could be ground or crushed fine before being placed in the ice-house, we should be able to secure a much larger quantity in the same house, and that a considerably greater body of air would be expelled from the house, making a difference of several months in the keeping. Could not some of the great machine manufacturers turn their attention to the matter?

I should very much like the opinions of some of your correspondents (perhaps Mr. Fish would be kind enough to enlighten us), whether ground ice would not keep better than ice in bunks of larger dimensions.—JOHN PERKINS.

I have no doubt at all as to smashed or crushed ice keeping longer than that which is merely roughly broken, especially if the crushed ice is well pounded together with heavy beaters after it has been so pounded. I have had no experience in the use of a machine for smashing ice. The most serviceable, I think, would be a powerful crusher with a rotary motion worked by horse-power, the crusher placed over the crown of the ice-well, and the carts being emptied close beside it. Unless the machine were made to suit other grinding and crushing purposes besides ice, there would be considerable outlay, and the infrequency of the use would come to be looked at seriously in an economical point of view. By breaking the ice pretty well before it was thrown into the hopper of the crusher, the cartloads might be hoisted nearly as quickly or more quickly than now, and that would be a great matter, as it is often important to secure as much ice as possible in little time, the frost often lasting only a short period. I trust other readers will give their opinions on this subject. My own is, that the more the ice is crushed the better it will keep in small houses. In large houses, where a great quantity can be looked after and roughly broken, the grinding would be of less consequence. Economically considered, even those who have a small house might find it cheaper to make an extra ice-bunker or two instead of obtaining a machine. I have no doubt of the desirability of the latter where it could be obtained, and it would save many a strained wrist from the brick-use of wooden or iron mallets by these not accustomed to the work.

So far as I know, Mr. Perkins is the first who has drawn attention to a machine for the purpose, and were there a demand for such a machine, there would be no lack of a supply. Meantime, I would mention from memory two very effectual modes of having ice. The first had relation to a small ice-house formed on the north side of a very deep bank overlooking with wood. Up this bank the ice had to be carried in baskets, after it was better pounded than ever I have seen ice since. It was then well pounded in the well, and clean shaven straw placed round the walls as the work proceeded. The position of the house prevented anything like moisture

remaining, and a drain two or three times trapped prevented all air entering from below. The labour in malleting the ice for this small ice-house, so difficult of access, was excessive; but the ice kept well, and was so much of a dense solid mass that a sharp pickaxe had to be used to take out a pailful or two, for two or three barrowloads at a time were not there thought about.

The other example was very different. The frost had been very severe. The water was fine and clear, without even a rush in it. The ice was from 3½ to 4 inches in thickness, and required much malleting to break it. As an experiment, a lot of ice was cut with sharp axes into blocks of 15 inches square. These blocks were taken and packed in a part of the house by themselves, and where they did not fit exactly a little water or the pounded ice was placed between to fill all vacancies, which instantly, owing to the frost, set like cement in a brick building. During the next summer, when the ice pounded in the usual way had sunk considerably, these columns of blocks stood alone in their glory. I attribute their greater endurance to the clearness of the ice, freedom from every weed, and the shutting out from them of all air, except what the water contained before it was frozen. Though this plan was interesting enough as an experiment, it never could be carried out largely except in very exceptional circumstances, whilst the crushing plan proposed by our correspondent could be carried out anywhere.—R. F.

BREAKING OF THE VINE.

"T. S. W.," in No. 250, says—"That irregular breaking in Vines is more owing to the different parts being exposed to different temperatures than to natural causes," I quote from memory and may not use the exact words, and the same experience prompts me to believe, that except in rare and exceptional cases, it is not necessary to bend, twist, or otherwise distort the canes in order to insure a good "break," but that proper attention to moisture and temperature is all that is required to bring this important part of Vine-culture to a successful issue. I say important, for the management after Vines have broken will be easy throughout; but if, on the contrary, they break badly, after-operations are rendered difficult and disappointing.

I have been employed in places where the bending of Vines is part of a system, and they have broken badly, yet the same Vines another season, bent in just the same way, have broken comparatively well. I have also seen Vines break alternately well and badly when trained straight up the rafters, in each case the health of the Vines being the same, and also the time of starting them—viz., January 1st, the best break being obtained in mild and dull weather when but little fire heat was required. Hence, it would appear that the evil is not constitutional, but atmospheric, and, therefore, more immediately capable of being remedied. I will briefly give the treatment as practised in two cases. First, then, let us start with a night temperature of 50°, and a rise by day of a few degrees, not being particular to a degree or two. Admit air a little slightly at the front as well as back of the house, syringe in the morning, and again in the afternoon—say at two or three o'clock, and close the house, which will not be opened again until nine or ten the next morning—no systematic moistening of the paths and floor of the house, except syringing the pipes on making up the fires at night. Who can be surprised at Vines breaking irregularly under such treatment? they being alternately subjected to an atmosphere as humid as that of a swamp, and as arid as that of a desert, in each case the evil being aggravated by the current of air from the front lights. Add to this, that the house being entirely close, the upper part would be for nineteen or twenty hours out of the twenty-four subjected to a temperature so much higher than the lower part as to cause the upper part of the Vines, be they bent or straight, to obtain the start, and as a natural consequence the general breakers in winter. The least evil which follows, is that all the best bunches are at the top of the house.

In the second case, the same Vines shall be trained directly to the top of the house, be started at the same night temperature, keeping the paths, walls, &c., of the house constantly moist, but the atmosphere not stagnant, damping them ten or twenty times a day if required. Let the day temperature be attained by nine o'clock in the morning, being a rise on the night temperature of 5° by fire heat, and of 15° by sun heat; in each case by unmitigating and unlagging attention keep it uniform. Let there be a system of airing, and let that system be rigidly

adhered to, giving air gradually as the temperature rises, and reducing the amount as gradually as it falls, leaving a little on all night at top, by every light if possible, under all circumstances and in all weathers. A little will do, from a quarter of an inch to an inch will be generally sufficient, but the Vines must be the guide. If the top buds are becoming too prominent give a little more air, but never open the front lights on any consideration. It is soon enough to do that when the bunches are showing their blossom. The uniform moisture which is by this treatment presented to the Vine is the most natural and congenial, and the assistance of the syringe will not be required, except, perhaps, a slight dash very early in the afternoon of unusually sunny days. I have observed that Vines which are peeled, scraped, and polished up, do not, as a rule, break so kindly as those which have but little done to them in this respect; the rougher surface of the unscrapped Vine retaining a more continuous and genial moisture around the spurs and buds, I believe, constituting the difference. Such is the treatment which was so successfully adopted by Mr. Young, late gardener to Viscount Barrington, and by which he for several years invariably secured good breaks, and with after-modifications fine uniform crops all the way up the rafters, excellent in character as regards size, colour, and flavour. For weeks together the Vines were not syringed, yet a red spider in the house was, indeed, a rarity, although close to the back wall ran a smoke-shaft, which was often so hot that the hand could not be kept on it. I remember one night taking the air off the top of the house for experiment, and in the morning finding that part 11° warmer than the lower part, and that proves that were it not for constant top air, the Vines must have broken irregularly. I have also proved, that in the case of a Vine trained vertically up a wall in the open air and a light placed against it, that part under the glass will break first.—J. WRIGHT.

respondent's attention to the experiment as detailed by Mr. Thomson. The Vine roots operated upon were roots that were chiefly bare of fibres, and that had been shortened and taken entirely out of the ground. When these are treated as stated, we have no doubt, from experiments of our own, that roots would be formed at the incisions, and most plentifully near the stem. Other successful experiments have been detailed in this Journal, in which fresh roots were abundantly protruded from the bottom of stems that had no connection with roots; but such experiments require first-rate management, and unremitting care. What we wish chiefly to add, however, is, that when we have made such incisions on the bare parts of large roots of Vines that were not separated from the fibres that existed at their extremities, then few of such incisions produced rootlets.

ABSTRACT OF METEOROLOGICAL OBSERVATIONS FOR THE YEAR 1865.

THE ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 3RD.

At the meeting held this day, Messrs. Cutbush & Son, of Highgate, made one of the most elegant exhibitions of forced flowers we have seen. So simple and graceful was the group, and so tastefully was it arranged, that it was the admiration of all who saw it, and fully justified the Judges in awarding it a first prize. It consisted of four pots of *Convallaria polygonatum*, or common Solomon's Seal forced (we are surprised this is not more frequently sent, as a centre; and surrounding these were nice plants of *Rhododendron Cunninghamii*, a *Dielytra spectabilis*, an *Azalea pontica* Taylor's Red, a *Vallota purpurea*, two pans of *Crocus versicolor*, two pots of Vermilion Brilliant Tulips, one of Tournesol Tulips, and one of each of the Hyacinths La Tour d'Auvergne, Vainqueur, and Amy.

Mr. Bartlett, of Shaftesbury Road, Hammersmith, who exhibited so successfully last week, was again present with a nice collection of twenty-five Hyacinths well bloomed, and some Polyanthus Narcissus, for which he received a second prize.

Messrs. Lacking Brothers, of Bayswater, received a first-class certificate for a pretty exhibition of forced flowers.

INCISIONS IN VINE ROOT.

In Mr. Thomson's "Treatise on the Vine" (chapter on experiments), he speaks of having made incisions in the old root or arm of the Vine after taking it up, and that from the lips of each incision roots were produced. I have this day bared the old root of my Vine with scarcely a fibre upon it, and have nicked it with a knife in several places. My gardener says "it will bleed to death," and that no roots can possibly come of this. Mr. Thomson says he cut "incisions." Does he mean simply nicks with the knife, or does he cut out a piece from the back of the root? thus, ———— A ———— All round the root I have laid fine fresh turfy soil and bones. Will my Vine die, or will it be improved, do you suppose?—A CONSTANT READER.

[We are not quite sure what kind of incisions Mr. Thomson made, but we should presume they would be simple slits—say three-quarters of an inch long, and one-eighth of an inch deep. Just as in the case of the slit in a layered Rose, or a layered Carnation, a little bit of crock or wood might be stuck in the slit to keep the wounds open, or rather their lips a little separate. There is little danger of the wounds bleeding, if made early enough. We shall be glad if Mr. Thomson will explain this process, more especially as we may have mistaken his meaning. From our own experience, however, we would direct our cor-

DETECTING BARREN STRAWBERRY PLANTS.

WHILST engaged in filling our Strawberry-house with plants that have been prepared for forcing, I have been led to remember what was said last spring about barren Strawberry plants, one of our gardening friends being disappointed, after forcing his plants, to find that very few of them showed any blossoms. It is quite evident from what he said about his plants that they were barren. Now, barren Strawberry plants may easily be distinguished from fruitful plants now, or while they are being prepared in the autumn. I prepare for forcing nearly two thousand plants every year, and I have had a little trouble myself with barren ones; for, after forcing my plants, I very often make plantations of them in the kitchen garden, and I frequently find some that have become barren. When I come to look for early runners from these plantations I find that I can take them much sooner from barren than from fruitful plants, but all that they will give me for my trouble will be leaves and runners. In the spring they first produce a

leaf, and then a runner, and so on alternately, and my firm belief is, that when Strawberry plants once begin to do that no one can make them grow any other way. It matters not how many runners are taken, for I find that these will produce nothing but leaves and runners again. It is quite possible for Strawberry plants to be unfruitful one year and very fruitful the next, but such plants grow very differently from the above.

—H. MASSLEY.

BOILERS.

As Mr. Robson has stated his experience with boilers for hot-water heating, and solicits information, I beg to add my mite.

We have an upright cylindrical boiler, without setting or covering of any kind, heating between 400 and 500 feet of three inch piping. The boiler is set in a room in the basement of the building to heat it, and it answers the purpose very well, thus confirming the opinion of Mr. Robson, that such boilers give off a very great deal of heat. The piping connected with this boiler is fitted with Truss's patent pipe-joints, the most simple, economical, and efficient joints I ever saw. Any man with ordinary ability may with these joints fit up a heating-apparatus for any purpose, and, if necessary, could take it down and erect it elsewhere without deterioration to any part of the apparatus. After the many useless things that have been foisted on the public by the aid of patents and otherwise, it is really refreshing to find something that really is what the patentee professes it to be.

We have one small upright cylindrical boiler set in brick-work, and I pity the man who has it to attend to, for the fuel often becomes fixed in the boiler, and not more than a third of it is consumed—not a very pleasant affair when a fire has been banked up to keep out frost. There are also two saddle boilers, one of them has water-bars for fire-bars, but I do not think that it is in any way the better of them. Taken for all in all, the old saddle-back is as good as any boiler I have yet seen. Coke is the only fuel used.—F. FRITTON.

Many and excellent are the articles which have appeared in *The Journal of Horticulture* at various times upon the boilers now in use for heating horticultural buildings. The last discussion elicited very laudatory remarks from some of your correspondents upon the many excellencies of tubular boilers. At that time the most approved form of those boilers had been but just introduced, and the articles then appearing, I have no doubt, set forth the previous experience of the writers. A more extended experience has now, however, been gained, sufficient, at least in a measure, to test their qualities of endurance—one of the qualities which appear to have been overlooked or very little thought of at the time. I wish those who have one of the above-named boilers under their charge to give us the benefit of their experience. Long lists of testimonials were published at their introduction, bearing the signatures of gentlemen whose names are a sufficient guarantee of the truthfulness of their recommendations. Most of us, however, have learned from that best of all teachers, experience, that an article may be very satisfactory for a time, but may ultimately prove less advantageous than was expected. Now, if the gentlemen whose testimonials in favour of tubular boilers could be induced to file an account of the subsequent performance of these, with the length of time erected, and an approximation to the amount of work done, it would be such a volume of evidence, either for or against, that a more sure test of their merits could scarcely be desired.

The writer whose article in the last discussion bore most upon the boilers in question was Mr. Abley, who threw out some suggestions for their improvement. His further observations would, therefore, be valuable. Mr. W. Gardener's and Mr. R. Carnley's articles directed us to "Clarke's Water-jacket Boiler," which is still largely advertised; and the late Mr. F. Chitty gave a description of Messinger's boiler which he appeared to think highly of. Perhaps his successor would tell what that boiler has done since Mr. Chitty's time. It is, however, regarding the upright tubular boilers that information is wanting.

In few words I will state my own experience of them. They are, when first erected, powerful, though not in all cases economical, are easily cleaned on the sides of the tubes next the fire, but not on the sides furthest from it, where they become clogged with soot and other products of combustion very much resembling coal tar, and which greatly affect their efficiency.

In one of the qualities that I most desire in a boiler—endurance, they appear to be very deficient. Two of them coming under my own immediate observation, have given way in less than four years after being put in, and two or three others that I have heard of have done the same. In all these cases there appears a strange coincidence, they having all cracked in exactly the same manner and place—through the lower rim to which the upright tubes are joined, on a level with and opposite to the top furnace-door. This fragility appears to me to be a fatal defect in this kind of boiler.

Can this cracking arise from a defect in the casting? Is it caused by the expansion and contraction of that ring of metal to which the vertical tubes are joined, and which appears to hang over the hottest part of the fire? (This remark does not, from the published drawings, appear to apply to "Clarke's New Water-jacket Furnace Boiler.") Or is it caused by the enormous pressure exerted by so large a volume of water, standing in most instances 10 or 12 feet above the bottom of the boiler? My own opinion is, that all these causes combined tend to produce the cracking. Shall we, then, continue to erect upright tubular boilers? Shall we return to the good, old and long-tried saddle? Or will some one tell us of, or invent a new one that will burn any kind of fuel, and that shall supersede all the boilers at present in use?—G. COOPER, *Harristown*.

NEW BOOKS.

The Treasury of Botany: a Popular Dictionary of the Vegetable Kingdom. Edited by J. H. LINDLEY, Ph.D., F.R.S., F.L.S., and THOMAS MOORE, F.L.S., assisted by Numerous Contributors. London: Longmans, Green, & Co.

BOTANICAL works of reference are, as a rule, occupied with such dry details and such minute distinctions that, even if comprehensible by the general reader, they are thrown aside in disgust. On the other hand, the works specially intended for popular use are for the most part by far too general, too little precise, often too incorrect in the information which they supply, to serve as safe guides on many points which arise in everyday life, where everybody is expected to know a little of everything; and notwithstanding all that has been said about a little knowledge being a dangerous thing, that little knowledge, provided only it be correct so far as it goes, is not, and cannot, in a properly-constituted mind, be otherwise than beneficial. In every branch of science, whether botany, or chemistry, or zoology, or astronomy, the end of all our knowledge has been to discover how little we really do know, to find step by step as we advance an ever-widening field before us, and to catch a dim idea of an unmeasured expanse in the future. Because, then, we cannot grasp all at once, not even a single one of the many branches of human knowledge, let us not turn away discouraged from the pursuit; but rather let us avail ourselves of the best helps to the attainment of the greatest possible amount in the least possible time. Such a help is the one before us, consisting of two closely and beautifully printed volumes of, in all, 1254 pages, and the contents of which are neither so scientific as to be unsuitable for the general reader, nor so popular as to be limited for the purposes of the student. They have, in fact, fulfilled the object proposed—namely,

"To bring together, into the form of a dictionary, a concise account of all the plants concerning which a general reader was likely to seek for information; adding thereto, where practicable, longer notices of the more remarkable species, together with such popular matter as would give interest to the otherwise dry technical character of generic or specific descriptions."

What the "Treasury of Botany" really comprises, therefore, is a short history of the economic use of plants which are known to possess special interest on account of the medicinal qualities or the economical uses of their species, or by reason of their beauty or utility as garden plants; while to these two groups has been added a still larger one, comprising a selection of genera serving as representatives of the whole series of Natural Orders and their subdivisions. The space devoted to each separate genus is necessarily brief; and, except in the case of medicinal or economically valuable plants, of which a rather fuller account is given, the object has been to convey some notion of the characteristics of genera or families, rather than to attempt an enumeration, much less a description, of the species of which they consist. For that a massive cyclopædia would have been necessary.

The above extract from the Preface is a fair outline of the object and scope of the work, and the mode in which it has been carried out is worthy of all praise. The plan, we are informed, was perfected under the supervision of the late Dr. Lindley, a man who, to his great botanical knowledge, united a

thoroughly practical mind, and a great talent for arrangement; but his failing health did not permit him to continue his superintendence beyond the letter C; the responsibility, therefore, of conducting the subsequent portion of the work devolved on his brother editor, Mr. Moore, of the Chelsea Botanic Garden, and most ably has he performed his task—a task which, from the very large amount of letter-press, the variety of the subjects, and the number of the contributors, must have been far from a light one. The names of the writers are—Professor Balfour, Rev. M. J. Berkeley, Mr. A. A. Black, Mr. W. B. Booth, Professor Backman, Mr. W. Carruthers, Mr. B. Clarke, Professor Dickie, Mr. W. B. Hemsley, Mr. R. Heward, Rev. C. A. Johns, Dr. Masters, Dr. Moore, Dr. Seemann, Mr. A. Smith, Mr. J. T. Syme, Mr. R. Thompson, and Mr. W. Thompson.

This list affords an excellent guarantee of the quality of the contents, and the articles are written in a clear and pleasant style, which, without sacrificing in the least the accuracy of the information conveyed, must add much to the popularity of the work. As an example, we will quote the article by Dr. Masters on *Argania* :—

“A genus of plants belonging to the family of *Sapotaceæ*. The calyx has ten sepals, in two rows: the throat of the corolla has five scales or abortive stamens, alternating with the five fertile stamens; anthers opening outwardly; style awl-shaped. *A. Sida corifolia* is the Argan tree of Morocco, in certain provinces of which it grows in woods. It is a spiny evergreen tree, with a trunk of considerable size, but of low stature. It gives off branches at a few feet from the ground, which incline downwards till they rest on the earth: at length at a considerable distance from the stem, they ascend. A tree mentioned in the ‘*Journal of Botany*’ for April 1854, measured 16 feet only in height, while the circumference was as much as 220 feet. The fruit is an egg-shaped or roundish drupe, dotted with white. These fruits are much relished by all ruminating animals, who, in chewing the end, eject the hard seeds, from which a valuable oil has been recommended in Australia and certain parts of Cape Colony subject to droughts. The wood is very hard, and so heavy as to sink in water.”

In addition to the other contents there is a copious glossary of botanical terms, besides which the English and French names of a large number of plants are given, and the whole is prefaced with descriptions by Dr. Seemann of vegetation in different parts of the world, in illustration of which there are twenty beautifully executed steel engravings. There are also numerous equally praiseworthy woodcuts, engraved by Branston from drawings by Mr. Fitch. It is scarcely necessary to add, after what has been already said, that we can heartily recommend the “*Treasury of Botany*” as a comprehensive and reliable work of reference.

Les Plantes à Feuilles Ornementales en Plaine Terre, par Comte LÉONCE DE LAMBERTYE. Paris: Auguste Goiz, Rue des Ecoles, 82.

Under this title M. le Comte de Lambertye, the author of an excellent work on the Strawberry, has commenced the publication of one on those plants with ornamental foliage which are sufficiently hardy to succeed out of doors in summer in the climate of Paris. In the public gardens of Paris fine-leaved tropical plants are introduced on a scale which is nowhere else equalled, nor, indeed, even approached, except at Battersea Park, where Mr. Gibson has adopted this new style of gardening with the happiest results. The plants thus employed having been chiefly confined to botanical collections, and not being for the most part remarkable for the beauty of their flowers, their merits for decorative purposes were overlooked until the last few years—indeed, to most amateurs and gardeners they are even now far from well known. A work, then, such as that which M. de Lambertye has commenced, giving the descriptions of these plants, and their cultivation, must be regarded as supplying a want.

The work is dedicated to M. Barillet-Deschamps, head gardener to the city of Paris, by whom the idea of planting-out tropical plants in the public gardens of Paris was first carried into effect, and who thus introduced a new style of gardening, which in France is daily becoming more popular. In the less-favoured climate of England the system has been successfully adopted in the warmer parts of the country. M. de Lambertye's work is to consist of three parts, of which the first, treating on the principal species of *Solanum* with ornamental foliage, has already appeared; the second is to be confined to *Cannas*, and the third is to include plants of other genera.

The author states in his preface that only such plants are described as he has himself grown, and that in the manner

which he describes. He commenced his collection of *Solanums* in 1862 with a few species, and in 1864 the number had increased to seventy-six; but on examination several were found to be incorrectly named, and many others not worthy of cultivation. In the part before us thirty are described, a number which the author remarks is still too large, for not more than eighteen or twenty are of undoubted merit. Each species is taken in alphabetical order, and the stem, leaves, and flowers are minutely described; then the culture is given, followed by general remarks on the ornamental character of the plant.

The species noticed at length are *Solanum aculeatum*, growing about 2½ feet high, and more remarkable for the abundance of its prickles than for its beauty. *S. amazonium*, about the same height as the preceding at the end of its first summer's growth; very ornamental from its bronzy yellow young leaves, and numerous large blue flowers; withstands the winter at Hyères in the south of France. *S. atropurpureum*, very striking by its deep purplish red shoots, numerous spines, and the white veins of the leaves, which are sometimes 18 inches long by 16 broad. Growing upwards of 6 feet high, it is suitable for small groups on lawns. *S. ariculatum*, growing 5½ feet high in the first year, spineless, leaves 18 or 19 inches long and a foot broad. Suitable for single specimens. *S. betaceum*, when well managed growing a yard high, with handsome leaves 15 or 16 inches long, and deep purple when young. *S. citrullifolium*, elegantly-cut leaves, and numerous flowers of a lilac shade throughout the summer. Grows about 3 feet high. *S. erinitum*—in peat soil at Monceaux this grows about 5 feet high, and the blade of the leaf is nearly 2 feet long and 2½ inches across. Shoots and leafstalks covered with long white hairs. *S. eleagnifolium*, suitable for small groups and front lines; requires support. *S. enneadonten* (Hort.), attains a height of about 5 feet, of an elegant habit of growth, leaves very small. Suitable for massing along with other species and for small groups on lawns. *S. ferrugineum* stated to grow 6½ feet high at Hyères, where it goes by the name of *S. verbascifolium*. *S. Fontanesianum*, about 5 feet high, suitable for groups of from three to five, and for mixing with other species. *S. giganteum* attains a height of 6½ feet in the second year of its growth, and though not the most ornamental species is nevertheless deserving of a place. *S. glaucum*, remarkable for the glaucous hue of the whole plant. *S. glutinosum*, sometimes sold as *ferrugineum* and *verbascifolium*; one of the finest species in the genus. Attains the height of 4 feet in the first season, with leaves 15 inches long by 9 inches across. Excellent for groups, and suitable for massing by itself or along with other species. *S. hyporhodium*, also known as *S. bicolor*, *discolor*, *purpureum*, and *galeatum*. One of the best of the genus, but requires plenty of heat. In the public gardens of Paris it grows 5 feet high, and has leaves 2 feet 8 inches long and 20 inches across, with ivory-white veins, the under side of a fine violet purple. *S. Jacquinii*, dwarf, about 9 inches high, elegant leaves, set with white spines; violet flowers, succeeded by numerous green and white berries. *S. Karstenii*, known also as *S. fraudulentum*. Very fine; tall; leaves very large. *S. laciniatum* grows 10 feet high at Hyères; very ornamental in its habit of growth, large leaves, and numerous large, bluish lilac flowers. *S. macranthum* grows 9½ feet high at Paris, and has leaves a yard long and 21 inches across. *S. marginatum*, one of the most ornamental; the leaves shining green, bordered with a white zone, which disappears as they become older, white on the under side, and on both sides when young. *S. maroniense* grows about 3 feet high; remarkable for the ferruginous hue of the young shoots and leaves, and the size of its violet-blue flowers. *S. pyracanthos*—its recommendations are its light and elegant character, and the fiery hue of its numerous spines. *S. quitense*; large velvety green leaves, with an amaranth tinge reflected from the veins and hairs. *S. reclinatium*, nearly allied to *S. laciniatum*. *S. robustum*; grows 4 feet high in the first year, and has leaves 30 inches long by 13 across. Of noble appearance, the stem, shoots, and the under side of the leaves covered with thick ferruginous down, the whole plant set with formidable spines. *S. Siegingii*, a noble species which should be in every garden. A plant 7 inches high, which M. de Lambertye planted out on the 16th of May, had by the 24th of October attained the height of 9 feet, and the leaves were a yard long, with a blade of about 26 inches by 20. *S. sisymbriifolium* and *S. tomentosum* neither of them so effective as some others. The former, however, grows rapidly, and has large white flowers, with bright yellow stamens, and ivory veins in the leaves; the latter, being dwarf, is useful for the edgings of beds. *S. violaceum*, of second-rate merit.

S. Warszewiczii, on the contrary, is highly ornamental. M. de Lambertye having only received this in 1863 from M. Weick, of Strasbourg, he has not been able fully to study and describe it. It grows 6 or 7 feet high in the first year, and has a noble appearance, especially when planted singly on lawns. The leaves are very large, the blade being nearly 30 inches long and more than 2 feet across.

This part of M. de Lambertye's work contains representations of *Solanum erianthum*, *robustum*, and *Warszewiczii*, but much cannot be said in favour of the style in which they are executed. It concludes with a comparative table of the thirty species described, which will be found useful as showing at a glance what are the particular merits of each in a decorative point of view.

Judging from the first part, and by the reputation which the author deservedly enjoys, this work will be found very useful by those desirous of information on sub-tropical gardening—a new field of which but little is yet known in this country; but, thanks to the excellent example at Battersea Park, a taste for it is rapidly growing up, and England, notwithstanding her disadvantages of climate, will not and must not be left behind in all that pertains to gardening progress.

WEATHER WISDOM

(Continued from page 27.)

As on a former occasion I endeavoured to impress upon your readers the absolute importance of a chart to assist the observer in remembering the previous fluctuations of the barometer, so now I propose to show more fully why a gardener should have no difficulty in noting down on a chart at fixed periods the variations of atmospheric pressure, and in the next place to consider why it is of the greatest importance for him to do so.

Those persons whose various duties call them every day many miles away from the scene of their meteorological observations, are unable, unless they possess self-recording instruments, to note down the many changes in the barometer and thermometers, or the different phenomena which have occurred during their absence. They may, indeed, hear from others who have been on the spot, that there has been a violent thunderstorm, a great rainfall, or a heavy fall of snow, at such and such a time, but unless the informant is a close observer, his remarks are not of much use to the meteorologist. Gardeners, on the contrary, can always make their own observations, and can be always near their instruments, if these have been provided for their use by a thoughtful master. Some people apprehending danger from the ever-watchful eyes of a thief, may hesitate before they leave a barometer in a shed or an outhouse; but even if a barometer is not carefully secured, unless it is of very small size, or a man is acquainted with the process which renders it portable, or observations are taken by means of an aneroid, I do not think there is real ground for alarm.

But to return to my subject. The great advantage which a gardener has over other observers is as follows:—He is always in the daytime, and in some places at night, near his instrument, and he can therefore note down at other hours, in addition to 9 A.M., the changes which occur in the height of the barometer. Very often the column of mercury falls considerably during the day, and returns at night, or by the next morning, to somewhat near the height at which it stood when the original observation was made, thereby deceiving any one who has not visited the instrument in the interim. I could give your readers many instances, but I think the fact will be admitted by all observers to be true. Now, from such oscillations of the mercurial column the gardener knows that the weather is likely to be unsettled, and cannot be depended on; but the other observer, from want of opportunity, and knowing nothing of the fall and subsequent rise of the mercury, anticipates different weather to that which he would have expected had he known of the changes during his absence. It may be urged by some that it is bad policy to place a barometer in the hands of a gardener. "It will cause him," they say, "to neglect his work, and to be continually running away and gazing at the glass, and dotting down the result on the chart." But it must be remembered that these records of the weather are not intended for scientific purposes, or for comparison with other barometers, but simply as aids to determine the weather which may be expected for a few succeeding days. For such a purpose hasty glances are quite sufficient, and a gardener would not, I am sure, be drawn from his ordinary pursuits for any great length of time.

In showing your readers in the next place why a regular study of the barometer is of the greatest importance to a gardener, I ought to call to their recollection the great advantages and saving of life which have been of late years the result of the warnings which are now sent down to the seacoasts when gales and heavy weather are supposed to be impending. These warnings are the result of years of careful study of the barometer in connection with other instruments, and of the winds and other phenomena in the atmosphere in all parts of the United Kingdom, communicated to head quarters by the electric telegraph. A man who is forewarned is forearmed; and a gardener who studies the barometer, as well as the dry and wet bulb thermometer, and who observes the way of the wind, and the appearances in the sky, has it in his power to be forewarned as well as the sailor. "Cautel the gardener, then, on different occasions say to himself, "From my knowledge of the movements of the barometer, and with the aid of thermometers, I come to the conclusion that there may be gales, or rain, or frost, or snow, and I will be prepared for such contingencies?"

In conclusion, when those furious gales which burst out sometimes in the night find some inlet through an open window into the interior of a greenhouse, let an observer of the weather rejoice that the appearance of the mercurial column gave him some indications of probable weather, and that, acting upon that probability, he wisely shut up and secured the greenhouse, which, but for that precaution, might have presented to his astonished gaze in the morning—a glass-house without a roof. —X., Surrey.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHERE a large amount of produce is required from a small garden it is highly necessary that some arrangement should be made and followed up, so as to keep a succession of crops in the ground. In all situations, and under all circumstances, it is advisable to keep a cropping table, and note the time of sowing, planting, and gathering, with remarks on each description of vegetable. This table would be of great value in pointing out the time of sowing in that particular locality, so as to have the crops coming in at the time required. *Beans*, a sowing of Early Hangdown Long-pod should now be made in the open ground, where the soil is sufficiently dry to work well. *Cauliflowers*, the plants in frames and under hand-glasses to be kept clear of decayed leaves and litter, and to have all the air possible in mild weather. *Cherry*, sow Cole's Crystal White in boxes for the main early crop, it is an excellent early dwarf variety. *Cucumbers*, this is a good time to prepare for the principal crops; in making dung beds some brushwood or faggots should be laid at the bottom to drain off superfluous water; a narrow layer of the same material should also be built up with the bed under each rafter to reach from front to back, this will allow the heat from the linings to circulate freely, and at the same time will be a saving of dung. As soon as the seed leaves of the young plants are fully developed pot off in soil composed of two parts of leaf mould, one part loam, and one-fourth of white sand. *Lettuce*, remove decayed leaves from these in frames. Give plenty of air. *Mushrooms*, after the beds have been made a few days they should be examined every morning, so that it may be ascertained if the heat is increasing or decreasing. A thermometer may be thrust beneath the surface of the bed, and if, after two or three examinations, it does not exceed 80°, the bed may be spawed. *Radishes*, a sowing of Wood's Early Frame may be made on a warm sheltered border. Clear all the winter crops from decayed leaves as soon as the ground will admit of going upon it. *Sea-kale* and *Chicubarb*, let the roots for next year's forcing be planted immediately in rich ground, trenched; throw a hillock of old tan, ashes, or sand, round each crown to encourage it through the vicissitudes of the weather in February and March. *Tomatoes*, sow in heat immediately; also Sweet Basil, Sweet Marjoram, &c.

FRUIT GARDEN.

Let all planting be finished as soon as possible, and stake and mulch. Remember to drain thoroughly. Nowhere is this advice more necessary than in the orchard; although Apples and Pears are fond of adhesive soils, they will never prove profitable where water is allowed to accumulate. Examine all old or overborne trees; many trees of this character may be soon renovated by applying manure to the extremities of their

roots, as also by good top-dressings. Thin pruning is also of great use to Apples which are rather free setters; the same is also of great service to the Nonpareil class, to enable them to perfect both fruit and wood.

FLOWER GARDEN.

The plan for the coming season of gaiety should now be fully settled. All alterations should now be carried out without delay. In sowing the Californian annuals take care to consider when you most want them, they may be commenced with when wanted early. Finish top-dressing Auriculas, do not delay it while the weather is fine. Remove early blooms, and, if any plants look sickly, examine the roots: if from canker, apply the knife; and if from inefficient drainage, put more into the pots, if possible without breaking the ball of soil. Tulips are very rapidly coming forward, protect them carefully from frosts and cutting winds. Continue to watch for leaves that are cankered, and remove them as soon as perceived. Ranunculuses may be planted. After the beds have been evenly raked drills should be opened 2 inches deep and 3 inches from each other; into these the roots should be pressed down, covering them with fine and rich compost, slightly fastening the soil over them by giving it a gentle pressure. Dahlias may be put in bottom heat, and, as soon as the shoots are 2 inches long, strike them in brisk heat. Top-dress the beds of Pansies with decayed leaves, and manure from the Melon-pits reduced to a black unctuous compost. Peg down or remove all straggling shoots, and place bran under tiles as a decoy for snails, which will now, on mild nights, begin to be troublesome.

GREENHOUSE AND CONSERVATORY.

Still pursue steadily the directions with regard to temperature, &c. laid down in previous calendars. Slight advances in heat may be made on bright days, but if cloudy skies intervene revert immediately to decreased temperature, and let humidity proceed in the same ratio. Climbers may be looked over in the conservatory; and if an early display of their beauties is required, some of the irregular wood may be pruned away forthwith. Passion-Flowers and others may receive this treatment; but permanent plants, as Acacias, &c., will, of course, of themselves point out an exception. Those who are growers of the families of Epacris, Correa, Leschenaultia, Polygala, &c., will soon enjoy a rich treat. Frequent introductions and frequent removals are the order of the day here. Camellias require at this time abundance of water. Attend well to Eriacas, Epacrises, &c., that are potbound, some of these will require liberal watering. The winter has been so favourable for plants in the greenhouse in requiring so little fuel, that those who have been duly impressed with the importance of avoiding strong fires in plant-houses will find their account in the superior health of their stock. Increase warmth on sunny afternoons for a couple of hours, but let the thermometer sink again at night to 40° or 45°. See that all insects are extirpated before the growing season commences, and clear or sponge away all fungus or dirt of any kind from the leaves of plants—thorough cleanliness holds equally good with plants as with animals. Keep all stock neatly tied up; dress climbers. Tropaeolums growing should be constantly attended to. Shift some forward Pelargoniums into their final pots, and stake them out, if intended for specimens of high cultivation. Remove weak or crowded shoots, and secure a thorough circulation of air, without draught, to this house at all favourable opportunities.

STOVE.

Let all increase of heat take place on bright days, chiefly early in the afternoon, and then accompanied with a somewhat moist atmosphere. Have a batch of Gloxinias repotted and placed in bottom heat, using heath soil, loam, charcoal, and sand for compost in a fibrous state. Stove climbers on trellises, and growing in pots or tubs, that require to be shifted soon should be cut-in to fine fresh buds, preparatory to disrooting or shifting. Attend to the shifting of the Amaryllis tribe when requisite; as soon as they show signs of growth let them be introduced into this structure, and give a trifling amount of water, increasing it gradually as the leaves unfold. Pot *Gloriosa superba* in light, free, rich soil, putting two strong tubers in each pot, and plunge in a brisk heat until the shoots appear. Start such plants as *Stephanotis*, *Dipladenias*, *Clerodendrons*, both young and old plants, and recollect that a nice bottom heat is what they delight in.

FORCING-PIT.

Continue to introduce Roses, Lilacs, Sweet Briars, &c., for succession, and maintain a temperature of from 65° to

75, with plenty of moisture in clear weather. Fumigate whenever green fly appears, and syringe the plants whenever the weather is favourable. Some Gardenias must be started in the warmest corner of the pit. This pit will be rather too warm for the Geraniums, but a good stock of the forcing kinds should be started in some of the forcing-houses.

PITS AND FRAMES.

A calculation should be made as to how far the inmates of these structures will be able to supply the masses in the pleasure ground. No doubt damp has reduced the numbers of some kinds. Strong plants of Verbenas, Fuchsias, Petunias, Heliotropes, Salvias, Calceolarias, &c., or pots of store plants of these which had become established in the autumn, should be removed forthwith to some of the houses or pits at work to enjoy, if possible, a moderate bottom heat. These will quickly furnish abundance of cuttings, which should be slipped off and propagated. Water sparingly here at present.—W. KEANE.

DOINGS OF THE LAST WEEK.

Variations of Temperature—Ice-houses.—We expect to hear many and different accounts of the results of the severe though short snowstorm; but these can hardly be more diversified than the accounts we have received as to filling ice-houses, or the impossibility of doing so. Some of our friends and correspondents obtained some ice on the 11th ult., and plentifully on Friday the 12th; but the snow commenced falling with us when there was scarcely a crust of frost, and the softness and warmth of the ground no doubt caused it to melt all the sooner when the thaw came between midnight of the 12th and the morning of the 13th. On Friday we could not have done anything with ice. There was only a thin film on our ponds that would not stand the touch of the ice-hook; and that was protected by a covering of snow, which prevented the keen frosty air of the afternoon and evening having much effect upon it. From throwing water over the snow so as to melt it there was plenty of good ice on the morning of the 13th, but then the sleet and rain soon made the work wholly unsuitable for men and horses. What surprises us is, that so many collected so much ice on the 12th, when we had none worth going after. The snow and the thick atmosphere in our case must have prevented freezing, and we conclude that there must have been a clear atmosphere before the snow came, or between its ceasing and coming on again, so as to permit of freezing. The only regret in our case is, that, for making sure, we did not roll and cart a lot of snow on the Friday morning before the frost became severe in the afternoon, as then we might have made ourselves tolerably sure of a supply for another year, and snow does not wet and hurt men like heavy sleet. If another chance occur we must not wait for the ice to be so thick as we could wish it to be, as we are hardly safe for another season; and what is down in the well with us always decays faster than that high up near the dome or the doorway in these old-fashioned well-houses—a fact which first impressed us with the feasibility, and even desirability, of having ice-heaps, and even ice-houses, entirely above the ground level. The latter, built with double walls, and a space of confined air of from 6 to 9 inches in width between them, and with a wide overhanging roof, also double—the outer one of thick thatch or heath—ought to keep ice as well, if not better than any well sunk in the earth.

The ice-house chiefly used here is one of the old-fashioned wells, with a long passage and several doors. It had been built with double walls, but the inner one had been taken out before our time, for what reason we know not. The ice keeps well—has several times lasted within a few weeks of two years, but we like to fill the house if we can every season. Though we should leave the present passage for taking out the ice, we would take the first opportunity of so changing the road as to have the ice put in by a hole in the crown of the arch, and thus much labour would be saved, as it requires three men, generally, standing in the passage, to shovel the ice past them, between their legs, until it reach the well. Nor is this the worst of it, for the notes and the recollections of a good many years have convinced us, that of all the men employed on ice-days, taking it off the water, filling carts, breaking at the ice-well door, pounding and packing it inside, and shovelling it along the passage—those performing the latter work have been more liable than the others to suffer from colds and attacks of rheumatism afterwards, however well their boots were protected, and their legs secured, by non-conducting materials.

Though, as stated above, ice may often be procured in our uncertain climate under unfavourable circumstances, we may add for beginners that the most favourable circumstances for insuring ice keeping well are obtaining it from the clearest possible water, free of dirt, weeds, straw, or chips; securing it if possible when the temperature is a long way below the freezing point, and then stashing it at least superficially well for all the bits like road granite to be embedded in the finer snow-like mush below, so that all may be pounded down together with a little air left in the interstices as possible. If the air is keen and frost a little water may be added in pounding to fill up all crevices. If, from the heat of the sun when carting, or the high temperature of the atmosphere, any water should come out of the cart along with the ice, then there will be plenty of water for consolidating the mass without adding more.

We may here add that though the ice-house is very often under the care of the gardener, he himself rarely derives any benefit from its retarding or cooling influence, at least, unless in rare cases. We have concluded that the vegetables and fruit that were retarded in an ice-well—even its passages—suffered much in flavour, and just in proportion to the time they were kept in the low temperature. We have also been informed by first-rate cooks that even hanches of venison, however carefully wrapped up, likewise lost in flavour when long kept in the ice-house. For the cellar, in securing iced water and ice-land wine, and for confectionary, for the larder, and for making ices in the usual way, ice is invaluable as a luxury in summer, and in many cases it is so valuable for medical purposes that all gentlemen who can afford it should have an ice-house. Where much ice is wanted it would be advisable to have the ice-house as a part of the offices instead of at a distance from them, and then a stone-floored and a marble-shelved sort of ante-room close to the ice-well could be made, where milk, butter, and meat could be kept cool, without being directly exposed to the damp that ever comes from an ice-well in summer.

Perhaps here, too, we may also repeat what we think we stated last season—that where ice has to be brought from a distance, strong made tubs, lined with 2 inches of cork, and with double lids, the outer one also lined with cork, are very useful for keeping the ice from a week to ten days in the hottest weather. If any one choose to take out a patent on this subject we will make him the present of an idea, which, if reduced to practice, will make these tubs even better than they generally are, and that is simply by leaving a close space of 1 or 1½ inch between the wood and the cork. We do not see how a double tub, even of wood, each tub 1½ inch thick, with a 1½-inch space between them, closely fitted top and bottom so as to keep the space between air-tight, would not be quite as good as or better than the present tubs with their linings of cork. In such tubs it is very common to place a pitecher or an earthenware vessel full of water to become cooled, but when that is done the ice placed round it ought to be pure, for if taken from dirty water we should not like to drink the iced water if we know it. A better plan every way is to have an iron or tin vessel fixed in the middle of the tub, with a good lid, and a pipe with a tap attached passing from its bottom through the tub, so that water may be drawn off without lifting the lid and exposing the ice. This iron vessel should leave enough of room for bottles of wine to be placed among the ice round the sides of the tub. Some people consider a glass of water thus iced one of the greatest delicacies in the hot summer months. Judging from our own experience, such iced water should be partaken of with great reserve and care. Would some of our medical friends be so good as to give us their opinion?

RICHEN GARDEN.

Made the most of the dry days we had in surface-stirring among all young crops, digging, and trenching; but Wednesday and Thursday brought us another succession of wet days, which greatly abridged all out-door operations. Gave plenty of air to everything under the protection of glass in mild or wet days, by *tilting the sashes* back and front. Where there is much of this sort of work to do, it is true economy not to depend on anything comestable, but to have pieces of wood prepared on purpose, and have these fastened by a string to the plate opposite the centre of each light, so that they may be used easily, and always be at hand when wanted. However small the quantity of air given, even to cold frames, in severe weather, it is always preferable to tilt up the sash instead of sliding it down. When slid down rains are apt to enter at the back, and the cold air strikes the plants at the back at once. When the sash, without being slid, is tilted up at the back, the cold

air cannot at once reach the plants without passing through the warmer air issuing out. For very flat frames or pits good tilters-up may be formed of pieces of board 1 inch thick, 6 inches wide, and 8 inches long, cut diagonally with a saw, so as to form two triangles out of the parallelogram, each of these triangles making a nice tilter; and on raising the sash, by inserting the thin point of the triangle, it is easy to give air from half an inch to 6 inches. When the sashes of frames or pits are more steep, the tilters should be formed of squares 10 inches by 8 inches, cut in two diagonally as above, and then each triangular piece should be cut into three or more square notches like the sloping stage in a greenhouse, as these horizontal cuts in the tilter hold the sash more firmly, in the time of winds especially. The fastening these tilters with a string so as to be always ready, though a simple matter, is a great advantage. If loose, they are always out of the way, covered up, or lost.

The ground being so wet, sowed more Peas in tiles, boxes, and turves under protection, so as to put them out when the ground is nice and mellow. Planted out a lot of Dwarf Kidney Beans in a bed where fire heat can be given, turning them out of small pots when well rooted, and when the soil was nicely warmed for their reception. After this time they do very well in beds; but if we had not been scarce of nine and ten-inch pots, we most likely would have used them in the same place, as they could have been moved at any time—a matter of importance when room under glass is scarce. After this time a syringing in sunny days with clear soft water at a temperature of 90 will do much to keep them healthy and clear of insects. After this, the soil used in growing them may with advantage be more compact and lumpy. During winter a lighter loam suits them better.

Placed some Sea-kale and Rhubarb in the Mushroom-house; and spawned in the beginning of the week, and earthed-up in the end of the week, another piece of Mushroom-bed. We have also turned over in the shed some manure for commencing another piece. Managed to catch some great adder-like snails at night; but not before they had scooped out all the gills from the insides of some large Mushrooms. We are never troubled with them on our first beds. No doubt they come in with the material of the later beds. It is of no use looking for them, unless at night. They like fresh brewers' grains rather better than Mushrooms. Woodlice have not yet troubled us, and seldom visit us much in the house until March. Potted-off Cucumbers, and will give some large plants large pots, to fruit in these in a pit where hot water will assist them. Put up a bed for a two-light box for the first out of doors, as we are very short of fermenting material. Turned over some old hotbeds, that after growing Melons had been used for many purposes during winter, as for bedding plants, slowly bringing on Strawberry plants, &c., placing all the very decayed materials in a heap, as we cannot well wheel anywhere owing to the damp and wet, and saving all capable of fermenting again, to mix with some hot tree leaves, so as to give a help to a lot of early Potatoes. A little heat at the bottom assists them very much; too much heat is more apt to encourage tops than numbers of nice tubers. The shooting season being over on Thursday, must try and collect a lot of tree leaves for all such purposes. Set a number of figure-4 traps to catch mice, which are more than usually troublesome this season. Sowed Celery, &c., in pots where a little heat could be given. The incomparable is a beautiful dwarf White that stands well; but it does not grow so fast for an early taking up as Cole's White and some other kinds. The flavour of the incomparable is excellent, and we have not for several years seen a run head until well on in the spring. To raise the young Onions out of doors, put a number of large Onions that were beginning to sprout into leaf mould, in a warmish place, to produce small Scallions for salads, instead of so many young Onions. Chives grown in heat come in well also for this purpose. A good stock of Mint, Fennel, Tarragon, and Sorrel, should also be put into heat or under protection, so as to have plenty as wanted. Trenched-out a lot of Horseradish. This always commands a good price in the market, and is best when strong and young.

FRUIT GARDEN.

Proceeded in favourable weather with pruning fruit trees so as to have work forward, and in wet days thoroughly washed the woodwork and glass in the orchard-houses. Vines and Peaches in houses with their roots out of doors should be protected from changes of the weather by litter-thatching and board-coverings. We have done less than usual in this way owing to being scarce of material. In early houses, *Grapes*

coming into bloom, should in this mild moist weather have rather a dryish atmosphere, and the bunches showing bloom should have a dry hand gently passed over them to disperse the pollen. For this purpose, so as to insure good and regular setting, we know no plan of shaking or brushing equal to the gentle touch of a dry hand—that is, doubling the hand, taking the bunch in it, and gently drawing the hand over it. By this means we have found that Muscats set freely, even when they are not in such a high temperature. Note that during the time of Vines being in bloom, it is only in the mild moist weather we have had, that we would recommend the dryish atmosphere at blooming and setting-time. In weather in general, it should not be too dry at such a time, as, if the atmosphere is very dry, the capsule clings so closely round the parts of fructification, that the anthers cannot have full play on the stigma. More moisture in the atmosphere gives more elasticity to the capsule ring, and the anthers have more free play; but in all early forcing of Vines, we would recommend a dry hand being drawn over every bunch when in bloom. This is soon done. The best time is a sunny day.

On the other hand, Peaches when in bloom should have rather a dry atmosphere until the fruit is set. On a sunny day it is well to use a board rapidly waved over the trees to disperse the pollen, or in some cases to use even a feather or a fine camel-hair brush. We have known Peach-houses that showed a fine lot of bloom carry little fruit, because the house was kept much too moist when the trees were in bloom. A drier temperature would have caused them to set more freely. If trees are in bloom now in such mild moist weather, the moisture in the borders will sufficiently counteract the little fire heat that will be necessary. If the weather turned cold and frosty, the paths and borders might be syringed and damped, and a few evaporating-pans might be placed on the heating medium; but whilst Peaches are in bloom anything like steaming hot-water pipes and flues should be avoided.

Figs beginning to move had better be thinned as to the shoots, when it is seen what can best be spared. The shoots left and showing fruit may have the terminal bud nipped through with a knife or between the thumb and finger, which tends to throw the organised sap back to support the young fruit. When the young fruit appears, care must be taken that the roots are not dry, or the fruit will drop to a certainty. If from any cause the soil has become dry, and the dryness is not removed before the fruit shows, then the dry soil must be moistened by degrees. Too much moisture at once will cause the fruit to drop by extra stimulus. After the fruit begins to swell, the plants must be strangers alike to dry roots and stagnant moisture. As we kept in bearing our Figs in-doors a little into November, they are just now beginning to move. From the 1st to the middle of October is late enough for Figs to bear, if an early crop is desired from them. We covered part of our trees out of doors with spruce branches, anticipating a little severe frost; but as the thaw came before we finished, we will let them alone until we see the signs of another frost. Some of these trees we mean to allow to hang a little from the wall in summer. We have proved that where the place is at all sheltered and warm, Figs even out of doors do better when thus treated than when they are pinned-in with nail and shred, or string, to a wall. The remarks at pages 90 and 91 may help to convince others of the same.

Strawberries in pots under a little protection received plenty of air; and those under glass, set on reversed turf, were watered in hot days, and with less care, as there could be no stagnant water. Plants set in saucers were watered with care; and at this season of the year, and in such mild moist weather, no water was allowed to stand in the saucer. In such weather care should be taken that the water is not poured over the crown or bud. Plants in bloom should have all the air possible, and in such dull weather be shaken with a small brush or feather. When the blossom and the farina of the anthers are dry, a large fine feather is as good as anything else for brushing along them, and even the hand passed smoothly along them will do good. In fine sunny days they will set well enough without any such care; but if they do not happen to set, and we have used no means to help them, then we are apt to accuse ourselves, and self-accusations are the worst of all to bear.

Potted off Melon plants, and sowed some more to be in readiness, though as yet we can see but little space we can appropriate to them. If we could, we would always raise young Melon plants in a sweet dung hotbed. The plants generally have thus a vigour and a sturdiness which they rarely have

when raised by another heat in the dry state, either from flues or hot water, though in either of such heats they will flourish very well after they have become stout plants. There are many crops that thrive better in an old-fashioned dung hotbed than by any other heat we can give them. We have grown Cucumbers most successfully from first to last with the help of the old flue, but we never had such nice young plants of Melons from flue heat as from a dung hotbed. There was more trouble at first with dung beds than with hot water, or even with flues; but many gardeners who now have enough of hot water are beginning to feel the want of the old hotbeds for keeping the kitchen garden all right. Some may well extol the efficacy of Cabbage stumps, Pea haub, rotation of cropping, and rotation of trenching, for that is pretty well all the manure the kitchen garden can have. The old hotbeds were the grand foundation for plenty of luxuriant well-flavoured vegetables.

ORNAMENTAL DEPARTMENT.

Rolled the walks when dry, but not too heavily, so as to make them over-smooth now. Rolled also the lawns, as the worn heaps are becoming rather prominent in this mild, moist weather. Pruned the hardier Roses, Honeysuckles on arches, &c. Gave plenty of air to prevent damping in cold pits and frames. Will soon commence propagating what we are most scarce of for the flower garden; but as yet have little room or heat to spare. Pricked off some Calceolarias, Lobelias, &c., and sowed more Lobelias and Feathered Cockscombs. Potted lots of Geraniums, Fuchsias, &c. Pruned many more of the latter. Took Hyacinths to the house and conservatory, with other forced flowers and shrubs. Fresh regulated the conservatory, taking in a fresh lot of Cinerarias, and likewise fresh regulated the stove. Potting Mosses and Ferns. Brought Gloxinias beginning to show from a dark place to one where they could have more light to induce them to grow before potting them. Did the same as respects Achimenes, &c. Placed Gesnera zebrina where the tubers would ripen. Gave plenty of air and as little damp as possible to hardwooded plants, and in the worst weather proceeded with cleaning plants, washing pots, and preparing straw covers for protection. Made it a point to keep a look out for dry litter, rough hay, Laurel boughs, and Spruce branches, to be ready for temporary protection, for if a severe frost came suddenly, many things would suffer severely from being now so tender, unless, indeed, the frost should be preceded by a good fall of snow. Managed in a dry day to put some burnt earth and rubbish round Holly-hock stems, which will preserve them in the open ground to a great extent alike from wet and frost. Rare sorts may now be taken up with balls and placed in a mild heat for propagating, or suckers may now be removed. Cones of the dry burnt earth will be a good preservative for those left in the open ground.—R. F.

TRADE CATALOGUES RECEIVED.

- E. G. Henderson & Son, Wellington Road, St. John's Wood.—*Catalogue of Flower, Vegetable, and Agricultural Seeds.*
- F. & A. Dickson & Sons, 106, Eastgate Street, Chester.—*Catalogue of Vegetable and Flower Seeds, &c.*
- Robert H. Poynter, Castle Green Nursery, Taunton, Somerset.—*Retail List of English and Foreign Seeds, &c.*
- John McHattie, 136, Northgate Street, Chester.—*Catalogue of Vegetable and Flower Seeds, Gladioli, Seed Potatoes, &c.*

COVENT GARDEN MARKET.—FEBRUARY 3.

A MARKET dullness has prevailed in our market this week, and all descriptions of out-door and forced vegetables are more than sufficient for the demand. The Potato trade is dull also, and prices are receding in consequence of large arrivals, both coastwise and by rail. We have received a consignment of Pines from St. Michael's of remarkably good growth and quality, varying from 4 to 5 lbs. in weight.

TO CORRESPONDENTS.

We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

VEGETABLE MARROW (Notice).—Any seedsmen who has a large business would supply you if you merely asked for "Vegetable Marrow seed." The fruit ought to be of a whitish green colour, and oval in shape. The "Melon Vegetable Marrow" is for preserving, the jam made from it tasting like Apples.

ESSEX RIVAL PEA. In reference to "NICKERBOER'S" inquiries about my Essex Rival Pea, I wish to say that I shall have much pleasure in giving an answer to his inquiries provided he give in his proper name and place of abode, that being my only reason for taking no notice in the first instance, and I also wish to know by what the Pea synonymous to the Essex Rival is called in Leicestershire.—T. ELEY, *Sible Hedingham.*

ICE-PLANT CULTURE (M. S.).—Sow the seeds in light sandy soil in a pot or pan, and if you have the means of potting them off into small pots singly for a week or two it will be all the better. Plant them out on some dry sandy bank in the full sun about the same time as bedding plants are turned out, and they require no further attention. Avoid a windy or cold place, for otherwise the plant will not thrive; usually, however, it is of very easy culture, and looks all the better if well exposed to the sun.

PEAS OF GOOD QUALITY (T. H.).—The varieties most admired at table are the various kinds of Marrow, both Green and White, and they may be sown at intervals of ten days from early spring up to the middle of June, or even later if the situation is moist. The best-flavoured Peas at table are not, however, the best croppers, and many growers prefer some other varieties, of which Champion of England and Veitch's Perfection are good examples. For very early or very late supply recourse must be had to the White kinds, of which there is no lack, all more or less good.

BLOOD MANURE FOR VINE BORDER (Box 5).—We cannot confidently recommend you to use blood manure to an external border unless it is of very limited extent, and full of roots requiring strong feeding. Blood manure has a tendency to sour and sadden the ground to which it is applied, and unless that ground is very light and porous it is better not to apply such substances as blood; we would rather use liquid manure in a clear state, not thick and muddy, for when so it is apt to produce the same results as blood manure. The latter may, however, be mixed in some compost heap, and be made very useful in many ways.

BANKIAN ROSES BEDDED-OUT (J. N.). It is but seldom that we have met with this Rose in the condition you describe—*ie.*, bedded-out and pegged down, and we fear it will only be in fine seasons that it will do well. It would, however, be well to cut out all rampant shoots early in the season. Some plants that we have against a wall require this to be done twice during the summer, leaving all short spurs, which we shorten in much in the same way as in pruning fruit trees, and they bloom abundantly. Other Roses of the same kind against pillars are treated in a like manner. We believe that the same treatment will do for Cloth of Gold; but we have not seen it in any other position than against a wall, and there it is best to thin out some of the longest shoots, and leave some of the shortest at full length. The treatment of this Rose, however, is by no means so satisfactory as it ought to be, or rather its treatment as a bedded Rose has not ensured its success in any but the most favourable situations.

HOTBED FOR STRIKING CUTTINGS (Idem).—There is nothing better than horse-dung for this work, and if there be tree leaves to mix with it so much the better; if not, let the dung be thrown into a heap. As it will heat in a couple of days, let it be turned then, two days afterwards, and also on the fifth day, and if time will allow, let it remain for four days longer, after which time give it another turning; the hotbed may then be made about 3 feet high, and the frame placed upon it. A covering of sedge-sticks forms a good medium for plunging or half-plunging the pots of cuttings or seeds in. Such a bed is invaluable.

LIQUID MANURE (Factor). To vacant ground about to be dug for planting Cabbages, warts the house sewage may be applied, in bucket to a square rod, and undiluted. For plants in pot it should be mixed with six times its bulk of water. For trees and shrubs growing out of doors in the borders it should be diluted about half as much. Do not apply it to any plant, tree, or shrub, except whilst growth is active in the spring or summer. For four postage stamps you could have, free by post, from our office, "Manual," in which are much fuller directions for the use of house sewage and other liquid manures, &c.

POTATOES (Shrove). You cannot have better varieties than the Ash-leaved Kidney and the Fluke. Plant very early—not later than beginning of March.

POTATOES (Champion). No Potato does so well after a crop of any Potato the previous year. Change of crop, rotation of crops, is always desirable. The reference you seek for is No. 231 of this Journal.

VERBENA CUTTINGS (J. F.). Where the weather was unusually dry Verbenas were much infested with thrips last season; and if weakened by these insects, though they were cleaned as well as possible, more than the usual quantity of cuttings would be apt to go off; otherwise there was nothing peculiar in the season to injuriously affect Verbenas, and yet it is true, as you say, that they have not done so well as usual in many places. Will some of our friends state their views on the subject?

VINE PLANTING (W. Ross). You had better adhere to the old plan. See the article by Mr. D. Thomson. The practice of another head gardener corroborates most of the experiments which he has made.

CHAMBER UNDER GLASS-STRUCTURE (W. F.).—There will no doubt be an advantage in having a chamber beneath the roots of your Vines, heating that chamber at pleasure, having cold air admitted to it at will, and heated fresh air also taken out of it into the house when desired. The nearer these openings are to the pipes placed inside and at the front of the house the better, as all your front air will thus be heated as it enters. With such an arrangement we would have preferred planting the Vines inside. Even without this ventilation from the chamber we do not see why there should be a necessary connection between the three pipes placed at the front of the house, and the drying-up so thoroughly the plants placed on the stage, or the impossibility of setting Muscat Grapes sufficiently thick, as the heat from the pipes may be rendered moist at will, and there is no necessity for giving much air by the front ventilators, except in the hottest weather; even then a great deal of front air often does more harm than good. If your drawing is correct, then we do not see any necessity for your proposed chamber being so deep.

VINES—EARLY POTATO (J. E. Bond).—The Muscat will do well in the early house; but it will ripen much later than the Muscadine and Ham-burgh. If the Muscat does so well planted against the back wall of the second house, why risk the moving it all to the front? Let it alone; bring it down the rafter, and cut one of the Vines in front to allow it to have room. If you must remove one, we would remove one West's St. Peter's. The Muscat is not more subject to shanking than other Grapes if the roots are not too deep, or the Vine too heavily loaded. For Vines and Peaches in a state of rest you may use half a pound to the gallon. Clay and sulphur with enough of water to form a paint, answer very well. For an early crop, nothing beats the Ash-leaved Kidney Potato.

PLANT CASE (O. H., York).—We think your proposed case would answer very well if you could place it inside of a window of clear glass—say 6 feet by 4 feet. We would only deceive you by saying that you could keep bedding plants in it, or propagate them successfully if the case stood in the passage, and had only a very subdued light. In such a case, and in such a position, you might keep a number of the smaller Ferns and Mosses. In a better position for light the case would answer admirably. Instead of the tank being 5 inches deep, we would be better pleased with it if it were 3 inches or 3½ inches. At 5 inches in depth you will find the lower part of the tank comparatively cool.

IRISINE HERBSTII AND VIOLA CORNETTA (J. G.).—Irisine Herbstii is a dwarf-growing plant, attaining about a foot in height as a bedding plant; and has reddish brown leaves. It is very desirable as a decorative plant; but in the flower garden as a bedding plant its foliage is frequently of a dull dirty brown, inferior to Beet in colour. Viola cornuta is a very free-flowering slate-coloured Violet, with fine deep green foliage, dwarf, and compact-growing, suitable for edgings to beds, and front lines of ribbon borders. It does best on moist strong soils. On dry, hot, gravelly, or sandy soils it does not grow sufficiently, nor bloom continuously enough for bedding-purposes.

MANKERING LAWS (F. J.).—Falling rich compost or thoroughly decomposed dung, you may sow Peruvian guano over the lawn during showery weather in April at the rate of 2 cwt. per acre, and give another dressing in the first wet weather in June, applying it immediately before rain, so that it may be washed in. The guano should be sifted through a sieve, with a quarter of an inch mesh to free it of lumps, which should be broken and again sifted. Any lumps that cannot be broken put in a tub, and water poured over them at the rate of a gallon to every 2 ozs. of guano, will, if stirred up previous to use, form an excellent liquid manure, either for watering the lawn or plants in a state of growth. Peruvian guano is the best.

SUPPORTS FOR HYACINTHS IN BED (Idem).—Your proposed supports will answer well; but we think you could buy them cheaper than make them. Common Hyacinth supports, which are entirely of wire, and sold by most seedsmen and all dealers in Dutch bulbs, would be nearer than those home-made, and such we recommend you to procure.

PLANTS IN NEWLY-PAINTED STOVE (One in Distress). We think that the injury to the plants proceeds from the paint, especially as the plants recover when air is given after the house has been closed some time. It is easy to account for bedding plants succeeding well in it whilst stove plants will not do at all, for with the former little or no artificial heat will be required, and the fumes given off by the paint will be very faint, whilst in the case of stove plants the fumes will be stronger from the greater heat and diminished ventilation. Had the paint been put on properly, and each coat allowed to dry before another was given, the smell and noxious vapours would have been gone in less than a fortnight after giving the last coat. Perhaps the wood was not dry when first painted. Your only remedy is to leave a little air on constantly.

MELON CULTURE (Heap).—For four postage stamps you can have free by post from our office No. 615 of our Journal. It contains an epitome of Melon culture by Mr. Bailey, late gardener at Nuneham.

LA JARDINIER FRUITIER (W. Terry).—This is published by Didot of Paris, and the price is 5s. monthly.

SCALE ON PEACH AND NECTARINE TREES (A Constant Reader).—Unmail the trees, and wash the trunks and every branch and shoot to its extremity with 8 ozs. of soft soap dissolved in a gallon of water, apply this wash with a half-worn painter's brush, brushing it well into every crevice, and being careful not to dislodge the buds on the last year's wood, as you will do if the brush be used too forcibly. This washing of the trees should be done now; but if the buds have begun to swell, the wash should only be used at half the strength for the portion of the branches where the buds are, but for the old wood use the full strength. The brushing should be sufficiently hard to dislodge the insects. When the trees become dry paint every part of them with sulphur vivum 2 lbs., an equal bulk of soot, and fresh lime 1 lb., mixed with soft soap solution made by dissolving 8 ozs. of soft soap in a gallon of water if the buds have not swelled; but if they have swelled considerably, then 4 ozs. must be the quantity used. Add sufficient clay to bring the mixture to the consistency of thick paint. Leave no part of the branches untouched, and most of the insects remaining after the washing will thus be killed or stifled. The first wash should be heated to 160° for the main, and 140° for the last year's branches.

COLLECTING WATER FROM GREENHOUSE (An Old Subscriber).—The most economical plan is to have a large hog-head fixed so that the water from the roof can run into it. One such cask well painted will last for a number of years, and if you have two of them holding, say, seventy gallons each, and connected by a lead pipe, you will generally have sufficient rain water for watering the greenhouse. If you object to the hog-heads as unsightly, then you may sink them in the ground, and have lids to them, one being covered with soil, and the water will not freeze in them in winter. If preferred you might have a tank of stone or slate, with the joints cemented, sunk in the ground and covered with slate, except an opening to admit a watering-pot, and that opening provided with a wooden lid. We have one of these 8 feet long, 5 feet wide, and 3 feet deep, and it holds sufficient water for a greenhouse in most seasons, but in the course of the last and previous year it was twice empty.

SOWING ACCUBA BERRIES (Idem).—When the berries are ripe, which will be known by their parting readily or falling from the plant, sow them in well-drained pans three-parts filled with turfy yellow loam two-thirds, and one-third leaf soil, and cover with a thickness of fine soil equal to the diameter of the berries. A gentle watering should then be given, and the pan placed in a cold frame. The soil being kept moist the seeds will vegetate, if good, in due season.

PINKS (C. D. H.).—They are evergreen herbaceous plants. The stems die annually, which is a characteristic of the herbaceous, but the leaves are evergreen.

CROQUET GROUND.—An Old Subscriber would be obliged by being informed what are the proper dimensions of a croquet ground.

CUCUMBER (A. P. W.).—The Long Prickly for market, and either Improved Manchester Prize or Hamilton's Surprise for exhibition. We do not know where the Potato, a cross between the Ash-leaved and Lapstoue, can be purchased.

LEAVES OF FORCED KIDNEY BEANS SPOTTED (A. R.).—You have thrips on your Beans. On examining the under side of the leaves carefully you will notice a very small narrow-bodied insect that is very quick and jumping in its movements. The best remedy is smoking several times, and a good washing with clear soft water at about 90°, but thrips are difficult to destroy, as though every one may be dead to-day, you will have a fresh brood ere long. As the Beans are about fit to gather we would advise removing the worst leaves, syringing the plants well with warm water, and taking all the pods you could; then clear all out, burn the plants, and smoke the place with sulphur, if there is nothing else alive in the house. We would then wash stage, walls, and floor, with water as near the boiling point as may be, and, when cleaned, introduce a fresh lot of plants.

APPLICATION TO THE BROKEN PARTS OF TREES (E. P.).—We confess we have not much faith in the practice of using paints or plasters as a preventive to further decay. A limb that is cut off horizontally may have a piece of thin sheet lead bent over the place after the wound has been made smooth to exclude wet; but the effort to resist decay must be made by the tree. It is best to cut off all splinters, leaving as small a wound as possible, and cover that wound with some plastic compound of cow-dung, soot, and clay. Resinous trees will bleed when cut or broken in spite of all application, and so will some kinds of deciduous trees when cut at a season when the sap is rising and the leaves undeveloped.

INSECTS (M. D.).—The little green flies found in the window belong to the genus *Pteromalus*, and are quite harmless in the perfect state. In the larva state they are parasitic in the bodies of other larvae, most probably in those of some wood-boring insect. Has "M. D." any worm-eaten furniture in his house? We fear some other domestic insect has stung, or perhaps bitten, his inmates.—W.

ASSURANCE COMPANY (G. Jackson).—We know nothing of the office. Such a question is not on a subject within our province; but we will add that he who trusts to any of the many recent insurance companies has not the organ of discretion largely developed.

NAMES OF FRUITS (J. E. P.).—Apples: 1, Elenheim Pippin; 2, Holland-bury.

NAMES OF PLANTS (G., Glasgow).—1, *Garrya elliptica*; 2, *Pinus lasiocarpa*; 3, *Cupressus thujeoides*; 4, *Juniperus sinensis*. (*T. D.*)—2, *Eriostemon myoporoides*; 3, *Cytisus racemosus*; 4, *Acacia arnata*; 5, *Veronica Andersonii*; 7, *Arbutus unedo*. (*B. P.*)—1, *Cyrtanthera lutea*; 2, *Colunera*; 3, probably *Lomaria alpina*; 4, *Iris pseud-acorns* var. *variegata*. (*J. B.*)—*Picea Nordmanniana*. (*E. C. E.*)—We believe that they are both *Ursas*. No. 1 *U. barbata*, but we are not certain about the other.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending February 3rd.

DATE.	BAROMETER.		THERMOMETER.					Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.	Wind.			
			Max.	Min.			1 ft. dp.		
Sun. . . 28	29.976	29.362	50	39	45½	44½	W.	.06	Densely overcast; clear; overcast; rain.
Mon. . . 29	30.018	29.266	45	29	46	44½	S.W.	.00	Clear; fine; cloudy at night.
Tues. . . 30	30.008	29.837	50	39	45	44	S.	.01	Fine; slightly and uniformly overcast; densely overcast at night.
Wed. . . 31	29.951	29.431	54	43	46	45	S.	.38	Fine; densely clouded; slight showers; mild.
Thurs. . 1	29.361	29.305	55	43	45½	44	S.W.	.37	Rain; boisterous; but warm at night with S.W. wind.

Sat. . . 3	29.897	29.533	49	32	47	46	S.W.	.25	Clear; boisterous, with heavy showers; fine; rain.
Mean. .	29.850	29.435	50.43	36.71	46.28	44.71	1.13	

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RAILWAY CHARGES—A GOOD EXAMPLE.

As exhibitors of poultry are striving to obtain from railway companies the advantage of having their birds sent back free of charge, which, surely, every reasonable man would consider ought to be the case, I would hold up the South-Western Railway Company as a good example. I have exhibited at various places, and have always been allowed back carriage for my birds by the South-Western Railway Company, and last week the same privilege was again granted to me by this Company, when my birds returned from Walsall. May other companies be induced to see this as a just principle, and follow "a good example."—J. De L. S.

I THINK if secretaries of shows would take the trouble to write to those railway companies over whose lines they expect fowls to travel to and from their shows, and ask that the birds may be allowed to come and go for a single fare, the boon would not often be denied. I had the pleasure of acting as secretary for a show held in the eastern counties last summer, and I took an early opportunity of writing to the Great Eastern Company, asking them to allow the fowls to travel free both ways. I did not succeed in this; but the Company at once

stated, that though they could not accede to my request *in toto*, they would allow all un-sold birds to return free. Now, if the Great Eastern, a Company never thought very liberal, had no difficulty in granting the concession I asked for (in part at least), I do not think many of the other companies would refuse to do as much if they were only asked in time, and the case were fairly and temperately laid before them. Of course, they will charge both ways if nothing is said about it, and they are not even asked to concede anything.

It would be better still if poultry exhibitors could induce the principal companies to establish some fixed rule, or rate, for the carriage to and fro of exhibition poultry. A memorial signed by the Poultry Club to each company, would, no doubt, lead to the consideration of the subject, even if we did not at once obtain what we asked for.—P.

I AM glad to see that this matter is likely to be well ventilated, and if your correspondent, "Y. B. A. Z.," or the Poultry Club will take it in hand, I will be my share towards the expenses incurred, whether arising from the printing of a petition and sending one to the heads of each railway company, or from the appointment of a deputation of, say, six gentlemen, to be nominated by the persons contributing to the fund, to wait on the Directors or Boards of the various companies. The latter course will be much preferable to sending petitions, for I think petitions, as a rule, are hurriedly passed over and do not

receive the attention they demand. Besides, if a deputation wait on the Directors, it can set forth the various grievances much better in a few minutes than can be explained in pages of print, and it might at the same time make the suggestions most likely to remedy the evils complained of. That poultry shows benefit railway companies no one can doubt; therefore, I think the Directors cannot object to meet us on more equitable grounds than at present.

Why cannot a uniform rate be adopted by each company for, say, distances above and under fifty miles on each line, up to an average weight for each hamper—I myself adopt a hamper of about 3 or 4 lbs., and if all exhibitors do the same, the average weight will not exceed 30 lbs.—the charges to be the same either by passenger or van train.

That railway charges are a great drawback to many exhibitors is well known. Take, for instance, the following variety of charges I have had to contend with during the last three months, and could the most enthusiastic poultry fancier patronise the company making such glaring mistakes? I sent to the Darlington Show two hampers, a distance of less than two hundred miles, *via* the Great Western and Midland Railways, for which I had to pay 10s. 9d. by van train; the same fowls and hampers came back for 6s. 7d. by passenger train. I also sent two hampers to the late Chelmsford Show, having to go on two companies' lines, the distance being under 110 miles, and the carriage to and fro was 15s. 3d., besides the birds arriving at the Show some five hours and a half too late for competition, though I took the precaution to ascertain from the railway officials at the starting point whether they would be delivered in time. In consequence of this I paid both fare and entrance fees for nothing, and am then informed by the Secretary of the company on whose line the delay occurred, that they are not responsible, though they detained the fowls some fourteen hours.

I think that a uniform rate will be much better understood than the present mode of charging, and the company sending the fowls back for nothing. If both advantages can be secured so much the better. Why cannot the "frank" system be adopted, just as in the case of the newspapers carried by most railway companies? In my opinion, its adoption would be a great boon, for exhibitors would then be able to ascertain at a glance the amount they would have to pay for carriage, which, at present is an impossibility, more especially when the birds have to go over two lines.

I think the Poultry Club being a body, will be the most likely to take the matter in hand; and the sooner something is done to bring about a remedy the better, for the grievance is very great at present.

I also think that every praise is due to "Y. B. A. Z." for his able article, and liberal offer to assist as far as lies in his power in bringing about reform. Do not let either names or funds prevent the affair being gone into in a thoroughly systematic way; and if all the principal exhibitors will attach their names to a petition, and express their willingness to contribute their share of the expenses incurred, the amount for each to pay will not be very great. As the charges stand at present we are great losers.—CANTON.

NANTWICH EXHIBITION OF POULTRY AND PIGEONS.

The promoter of this Exhibition has now for the period of seven years seen their Show annually improving, and certainly the meeting of last week presented to public view one of the best collections of both poultry and Pigeons at any local Show that we have seen for some time. Being ever willing to take advantage of the experience of former meetings, this Committee always seem to look forward only to the improvement of their annual Exhibition; no petty jealousies ever intrude upon the harmony of their actions, and hence in no small degree may be traced the almost unalloyed success that has attended it from its first institution. The Town Hall at Nantwich is exceedingly well calculated to afford a perfect light to every pen, and the show pens of the Society are very superior in their arrangement, whether considered merely as to the easy public inspection of the competing stock, or as offering perfect protection from outbreaks of temper between neighbouring competitors. The patronesses and patrons of the Society embrace almost every family of distinction in the neighbourhood, and consequently, under such favourable auspices the continued success of the Nantwich Poultry Show is fully secured.

Spanish fowls head of the list, and as faithful journalists, we must say not only was this breed not so good as at some of the previous meetings of the Society, but also that there was an extreme amount of

trimming of the faces in some of the pens. The *Aylesbury Ducks* were excellent, nor were the *Bonons* less deserving of our especial notice. *Geese*, as is always the case at Nantwich, were of extreme merit. Mr. Burgess, of Barleydam, exhibiting both *Emdens* and *Toulouse* that would be hard to beat at the largest of poultry meetings; nor can we speak otherwise than with equal praise of the two splendid pens of *Cambridge Turkeys* exhibited by the same gentleman. Of *White Dorkings* only one pen was entered, but they proved very good. The *Grey Dorkings* were extraordinarily fine well shown birds, Mr. Burgess again being a most successful exhibitor, with specimens of great merit and of exceedingly good plumage. The Hon. Mrs. Sngden exhibited some extraordinarily good *Buff Cochins*, as did Mr. Tudman, of Ash Grove, Whitechurch, Partridge-feathered ones. It is very rarely that so nice a collection of *White Cochins* is to be met with, though very limited in number, being only three pens. In the *Selling Class* were shown some perfect *Silver Poland* and some very fine *Dark Brahmas*, all of which speedily changed hands. The Committee's silver cup, open to all England, for the best pen of *Game fowls*, regardless of breed or colour, caused much sensation and a hard competition. Mr. J. Fletcher, of Stoneclough, near Manchester, was the successful competitor, with a marvellously well-shown pair of *Brown Reds*. It is a very rare occurrence to witness so great a perfection of feather, combined with such faultless condition, as existed in this pen; but it must not be for a moment supposed that the competition was an easy one, Messrs. Burgess, Galley, Green, and Dyas, showing pens that it would be difficult to beat when shown in the good condition that they were. The other *Game* classes were confined as to the competition to within a circle of thirteen miles of the place of exhibition, as in fact was the whole show, except the one class for *Game* before referred to. All these general *Game* classes were very good, and we were glad to observe, so far as trimming of feathers was concerned, that not a single attempt at deception was discovered. There were, however, we are sorry to say, three or four cases in which spurs had been most extensively tampered with in old cocks, in the hope to make them do good duty as cockerels. They were necessarily disqualified, but we are bound to say that we never before saw any attempt of the kind so artfully carried out. The *Game* hens were very good indeed, for the *Game* amateurs around Nantwich are evidently breeders quite as much for the pit as for the exhibition pen. For exhibition, a greater amount of care in matching the colour of the legs would be most desirable. For the Nantwich *Victuallers' Cup* the excellent *Brown Red* cockerel that proved the winner was soon claimed from Mr. Edwards, of Nantwich, at the price put upon it—viz., five guineas. The *Spangled Hamburgs* were all good, but the *Golden* varieties were undoubtedly the best of them. The *Pencilled Hamburgs* were not so well shown as they might have been. The *Silver Pouter* were perfection. The *Green Bantams* were not so good as we expected to find them.

Although the Rochdale Show, held simultaneously, no doubt took away a portion of the visitors, the attendance was perhaps greater than at any previous Nantwich meeting. Mr. Rhodes, the indefatigable Secretary, was unremitting in his exertions to please every one, and the success of the meeting may be attributed to a considerable extent to that gentleman's exertions.

DUCKS.—First, J. Sollen, Over Lane. Second, G. F. Ward, Wrenbury. *Chickens*.—First, J. Dean, Wharton. Second, J. Siddons. Commended, J. Heath, Nantwich.

DUCKS (*Aylesbury*).—Prize, Mrs. Hornby, Durnhall. Highly Commended, Mrs. Hardy.

DUCKS (*Bonons*).—First, H. Prince, Nantwich. Second, T. Burgess, Barleydam. Highly Commended, T. Burgess.

DUCKS (Any other variety).—Prize, T. Whittingham (Muscovy).

GEESE.—First and Second, T. Burgess, Commended, W. Furnival, Sould.

TURKEYS.—First and Second, T. Burgess. Highly Commended, E. Bowers, Brad Lane.

DORKINGS.—White. Prize, Mrs. Tollemache, Dorford.

DORKINGS (Grey).—First, and Silver Cup for the best pen of fowls in the Exhibition, T. Burgess. Second, J. G. Pearson, Market Drayton. *Chickens*.—First and Second, T. Burgess.

COCHIN-CHINA (Cinnamon, Buff, or Partridge).—First, Hon. Mrs. Sngden, Stapely House. Second, E. Tudman, Ash Grove. *Chickens*.—Prize, E. Tudman. Highly Commended, J. Withinshaw, jun., Nantwich.

COCHIN-CHINA (White).—Prize, G. Withinshaw, Nantwich. *Chickens*.—Prize, J. Dodd, Minshall Vern n. Highly Commended, J. Dodd.

COCHIN-CHINA (Cock Sweepstake).—Prize, Hon. Mrs. Sngden.

SELLING CLASS.—First, G. Williamson (Polands). Second, J. Heath, Nantwich (Brahmas).

GAME.—Cup, First, and Third, J. Fletcher, Stoneclough. Second, T. Burgess. Fourth, A. B. Dyas, Madley, Slop. Highly Commended, W. Galley, Nantwich; Green, Thornton-le-Moors.

GAME (Black Red).—First, R. Ashley, Nantwich. Second, J. Thursfield, Lightwood Green. *Chickens*.—First, T. Moore, Canal Wharf. Second, G. Warren, Market Drayton. Third, J. Whalley, Larden Green.

GAME.—Brown Reds.—Prize, T. Burgess. Highly Commended, T. Burgess. *Chickens*.—First, T. Whittingham. Second, T. Burgess. Third, R. Ashley.

GAME (Any other than Black or Brown Red).—First, R. Ashley (Duckwing Grey). Second, Miss Sadler, Whitechurch (Duckwing Grey). Third, R. Crewe, Burland (Grey). Highly Commended, J. Heath (Duckwing Grey). *Chickens*.—First, R. Ashley (Duckwing). Second, Miss Sadler (Duckwing). Third, R. Ashley (Pile). Commended, A. Robinson, Wrenbury (Duckwing); T. Burgess (Pile).

GAME (Cock Sweepstake).—Prize, J. Withinshaw, jun. (Black Red). Highly Commended, H. Oakes, Nantwich (Brown Red). *Hens*.—First, R. Ashley. Second, W. Gill-y, Nantwich (Brown Red). Third, T. Burgess (Brown Red). Highly Commended, G. E. Ford, Nantwich.

HAMBURGHS (Spangled).—First, T. Burgess. Second, J. Gleave, Church Lawton. Highly Commended, S. Armstrong, Radnor Green. Commended, J. Hitchenson, Davenham.

HAMBURGHS (Pencilled).—First and Second, J. Gleave. **POLANDS**—Prize, J. Heath. Highly Commended, J. Heath. *Chickens*.—Prize, J. Heath. Highly Commended, J. Heath.

POLAND COCKS (Sweepstake).—Prize, J. Heath. **ANY OTHER VARIETY.**—First, J. Heath (Brahmas). Second, W. B. Etches (Brahmas). Highly Commended, Hon. Mrs. Sugden.

GAME COCKERELS (Any colour).—First and Cup, S. Edwards, Nantwich (Brown Red). Second, T. Burgess. Third, E. Bowers (Brown Red). Fourth, D. Basford (Brown Red). Highly Commended, T. Burgess; E. Bowers (Brown Red). Commended, R. Roberts, Ravensmoor (Brown Red); J. Pedley, Nantwich (Brown Red); Messrs. Church & Holding, Nantwich (Brown Red).

GAME COCKS (Any colour).—First, J. Walley (Black Red). Second and Fourth, T. Burgess. Third, T. Latham, Nantwich. Commended, T. Burgess; E. Bowers (Brown Red).

GAME BANTAM COCKS (Sweepstake).—First, J. G. Pearson, Drayton. Second, T. Burgess. Third, E. B. Sugden. Commended, T. Stanyer. **CROWN IDL.**

GAME BANTAMS (Any colour).—First, T. Burgess. Second, W. Griffiths, Nantwich. Third, R. Ashley.

BANTAMS (Any other than Game).—Prize, G. Williamson (Gold-laced). Commended, T. Butler, Middlewich (White).

RABBITS (Long-eared).—First, T. Gaman, Nantwich. Second, W. J. Sheeh, Bilston.

RABBITS (Heavy).—First, W. J. Sheeh. Second, T. Gaman.

PIGEONS.

In *Pigeons* the Show was a very strong one. Carriers, Pouters, Barbs, and Tumblers, being very good. Azoin, Fantails, Jacobins, Trumpeters, Owls, and Turbits, were well shown. Among the class for varieties we noticed some excellent Spots, and some very inferior Porcelains shown as Icelanders. In the Dove class were some extraordinarily good White ones.

CARRIERS.—First, S. Cliff, Nantwich. Second, J. Withinshaw, jun. **DRAGONS.**—First, J. Withinshaw, jun. Second, S. Cliff.

POWTERS.—First, J. Withinshaw, jun. Second, E. Butterworth, Nantwich. Commended, J. Peak, Ravensmoor; J. Dutton, Dunbury.

BARBS.—First, J. Withinshaw, jun. Second, J. Hockenhill, Nantwich. Highly Commended, J. Hockenhill; C. Grocott, Nantwich.

NEWS.—First, J. Dutton. Second, J. Withinshaw, jun. **TUMBLERS (Any variety).**—First and Second, T. Crawley, Tarporley. Extra First, J. Dutton (Red Beards). Highly Commended, C. Grocott (Short-faced); J. Dutton (Silver).

FANTAILS.—First, J. Withinshaw, jun. Second, J. Chesters, Nantwich. Highly Commended, J. Dutton. Commended, E. Butterworth; J. Dutton.

JACOBS.—First, J. Hockenhill. Second, J. Withinshaw, jun. Highly Commended, J. Dutton.

TRUMPETERS.—Extra, First and Second, J. Dutton. Highly Commended, J. Withinshaw, jun. Commended, J. Withinshaw, jun.

OWLS.—First, S. Worsley, Nantwich. Second, J. Dutton. Highly Commended, R. Betley, Nantwich; J. D. Nixson, Nantwich.

TURBITS.—First, J. Dutton. Second, J. Withinshaw, jun. Highly Commended, J. Withinshaw, jun.

ANY OTHER VARIETY.—First, J. Dutton (Spots). Second, J. Hockenhill (Icelanders). Highly Commended, J. Withinshaw, jun. (Magpies). Commended, J. Dutton (Archangels).

DOVES.—First, J. Cooper, Nantwich. Second, J. Hockenhill. Highly Commended, W. Venables, Whitechurch; F. Peak, Hough Road.

SINGING BIRDS.

CANARIES (Yellow).—Extra, First and Second, S. Williamson, Nantwich. Highly Commended, S. Williamson. Commended, A. Tomlinson, Nantwich.

CANARIES (Buff).—First, R. Green, Nantwich. Second, S. Williamson. Highly Commended, A. Tomlinson. Commended, S. Williamson.

CANARIES (Various).—First, S. Williamson. Second, R. Green. Highly Commended, H. Prince. Commended, S. Williamson.

SELLING CLASSES.

LINNETS (Brown).—Prize, S. Williamson. Highly Commended, C. Emery, Nantwich. Commended, T. Williamson, jun., Nantwich.

LINNETS (Red).—First, S. Williamson. Second, T. Williamson, jun. Highly Commended, R. Williamson, Nantwich. Commended, R. Williamson.

SKYLARKS.—First, J. Willett, Nantwich. Second, D. Robinson, Nantwich. Highly Commended, J. Willett. Commended, T. Williamson, sen., Nantwich.

BULLFINCHES.—First, S. Williamson. Second, R. Williamson. Highly Commended, R. Williamson. Commended, W. Williamson, Newtown.

The Judges for Poultry were Edward Hewitt, Esq., of Spardbrook, Birmingham, and Richard Teabay, Esq., of Fullwood, Preston; and the prizes for Pigeons were awarded by Charles Cotton, Esq., of Crew, and Charles Bowles, Esq., of Chester.

NATIONAL POULTRY EXHIBITION AT ROCHDALE.

THE first Exhibition of the above Club was held at Rochdale on Friday, Saturday, and Monday last in a newly erected mill, the property of Mr. J. L. Stott, kindly lent for the occasion. We can congratulate the Club on succeeding in bringing together such a collection of birds as has never been shown previously in Lancashire. The entries numbered 556 pens, and, considering that the prize money offered did not exceed £200, we think that with the limited time the Poultry Club had at their command the result must be highly satisfactory to all concerned. A local Committee, forming a very effi-

cient staff, carried out the arrangements of the Show in the most able manner; and with the aid of Mr. Zurhorst, the Hon. Sec. of the Poultry Club, who is a host in himself, the Show was an immense success.

To commence with a few remarks on the various classes. Buff *Cochins* headed the list, and, although the entries were very numerous, the class was not particularly strong. Mr. Jennison won the cup with a pen leaving little to be desired. The other prize birds were also good. In *Cochins*, Brown or Partridge, Mr. Stretch's cup birds were very good; the competition, however, was unusually severe. Messrs. Tudman and Wood's representatives being of great merit. In White or Black *Cochins* Mr. Chase secured the cup with a fine pen in marvellous condition. *Dorkings* were a large class, numbering forty-five pens, and Lady Holmesdale added another trophy to many others by winning Captain Heaton's cup with her well-known rose-combed birds. White *Dorkings* were a small class, but the prize birds were excellent. *Spanish* formed one of the best classes in the Show; Mr. Jones's first-prize pen being particularly conspicuous, the hen being one of the best we ever saw. Many of the competing pens showed unmistakable effects of over-exhibition. Dark *Brahmas* were both numerous and good. Mr. Pickles had the cup with a very fine pen, after an extraordinarily close competition with Messrs. Mann and Boyle. Light *Brahmas* were also good; Mr. Parry's prize pen, however, had an easy victory. *Cize Coues* were a curious class; the cup was given to unquestionably the best birds, belonging to Mr. Zurhorst. *Hamborghes*, as might be expected from the locality, mustered very strongly, and were of remarkable quality, the most noticeable being Sir St. George Gore's Silver-pencilled. In the class allotted to them both the cup and second prize went to the same yard. The prizes in the other *Hamburgh* classes were well merited. In *Woods* capital White-crested Blacks were shown, as well as very fine Golden and Silver specimens. *Gans* were a strong competition. Sir St. George Gore taking the cup for Black Reds with a capital pen. Brown Reds were not so well represented; Mr. Fletcher had the first and second prizes, but the birds winning the latter were deficient in quality. In *Duckwings* and *Game*. Any other variety, Mr. Fletcher had both first prizes, the first *Duckwings* were coarse and loose in feather, and much inferior to the third-prize pen; the second-prize pen contained a very inferior hen, accompanied by a squirrel-tailed cock. A very good pen received high commendation. *Game Brahmas* were largely exhibited, three classes being set apart for them—namely, Black Reds, Brown Reds, and *Duckwings*; the former were very fine, but the cup was awarded to *Duckwings*. The first Brown Reds were particularly good in feather, but rather too lengthy and drooping in wing. Laced, White, and Black were all well represented.

Ducks were a fine collection, but we were surprised to find the first-prize *Aylesburys* contained a drake with an unmistakably yellow bill. *Rosens* were large, but the colour of the Duck in the prize pen was objectionable.

The Single Cock classes were well filled. The prize *Dorkings* of Lady Holmesdale and Mr. Harvey were both of very great excellence, and a most severe contest for the principal positions resulted in decisions in the order named. The single *Hamburgh* prize cocks were also very fine, the prizes being judiciously awarded. In the like classes for Single Black Red Game Cocks there was a good competition. The cup for the best single bird in each variety of Reds was awarded to Mr. Fletcher for a Brown Red cockerel, short in head, but well shown. Mr. Brierley was second with a remarkably good bird.

COCHIN-CHINA (Cinnamon or Buff).—Cup, C. Jennison, Belle Vue, Manchester. Second, C. W. Brierley, Middleton. Third and Fourth, T. Stretch, Ormskirk. Very Highly Commended, Hon. Mrs. Arbutnot, Inchmartine, Inchture, N. B.; H. Tomlinson, Birmingham; J. Gattell, Birmingham. Highly Commended, J. Bradock, York; A. Fenton, Rochdale; C. Jennison. Commended, R. White, Sheffield; E. Yeardley, Wisewood; W. Wood, Salford; C. Jennison; R. W. Boyle; G. Fell, Warrington.

COCHIN-CHINA (Brown or Partridge).—Cup, T. Stretch. Second, E. Tudman, Whitechurch. Third, J. Wood, Chorley. Very Highly Commended, J. Bell, Thirsk; T. Stretch. Highly Commended, E. Tudman; T. Bott, Barv, Lancashire; J. Stephens, Walsall. Commended, J. K. Fowler, Aylesbury; J. Horrocks, Middleton; J. Stephens; T. Stretch.

COCHIN-CHINA (White or Black).—Cup, R. Chase, Birmingham. Second, F. W. Zurhorst, Dundrum, Dublin. Third, Rev. F. Taylor, Keastwick. Highly Commended, Rev. F. Taylor; W. Dawson, Hopton, Mirdfield; W. A. Taylor, Manchester; Messrs. W. and J. Cople, Eccleston; R. Chase; Hon. Mrs. Arbutnot. Commended, F. W. Zurhorst; R. Smalley, Lancaster.

DORKINGS (Coloured or Silver-Grey).—Cup, Viscountess Holmesdale, Linton Park. Second, A. Fenton. Third, Sir St. G. Gore, Bart., Wirksworth, Derbyshire. Fourth, Mrs. Hurt, Derby. Highly Commended, T. Rogers, Manchester; J. F. Newton, Kirby-in-Cleveland; A. Fenton; Messrs. W. and J. Cople; Hon. Mrs. Arbutnot. Commended, R. P. Williams, Dublin.

DOUBLES (White).—First, H. Lingwood, Needham Market, Suffolk. Second and Commended, J. Robinson, Garstang.

SPANGLED.—First and Fourth, E. Jones, Clifton, Bristol. Second, Viscountess Holmesdale. Third, H. Lane, Ashley Road, Bristol. Highly Commended, Miss D. Pennant, Bangor, N. rh Wales; J. Newton, Silsden, near Leeds; W. Bone, Park Street, Bristol; J. Marchant, Hanson Lane, Halifax; A. Fenton; E. Jones; F. Crook, Forest Hill, Kent; W. Harvey, Bank Street, Sheffield; A. Heath, Calve, Wilts. Commended, A. Fenton; R. B. Postans, Brentwood.

BRAHMA POOTRA (Dark).—Cup, J. H. Pickles, Bridgeroyd, near Todmorden. Second, J. Mann, Shawclough, near Manchester. Third, R. W. Boyle, Extra Third, H. Lacy, Highly Commended, T. Pomfret, Preston; H. Lacy; F. Powell, Knaresborough; W. Hargreaves, Bacup; J. Wright,

Woodbridge, Suffolk; G. H. Roberts, Penwortham, near Preston. Commended, T. Pomfret; R. W. Boyle; F. Powell; G. H. Roberts; J. K. Fowler; Hon. Mrs. Arbuthnot.

BRAMA Pouter (Light).—First, J. Pares, Childown Hall, Chertsey. Second, H. Lacy, Highly Commended, E. Pigeon, Lymington; J. Boothby, Market Place, Stockport; J. Stevens, Macclesfield; Hon. Mrs. Arbuthnot, Commended, J. Pares; E. Sherrington, Chelmsford.

CREVE CLERS.—First, F. W. Zurlhorst, Second, Hon. Mrs. Arbuthnot, Third, National Poultry Club (Limited), Bromley, Kent. Highly Commended, Mrs. Hart. Commended, Mrs. Hart.

HAMBURGERS (Golden-pencilled).—First, J. E. Powers, Biggleswade, Beds. Second, Sir St. G. Gore, Bart. Third, W. Pearce, Hartford, Northwich. Very Highly Commended, A. K. Wood, Burnside, Kendal. Highly Commended, C. Tattersall, Waterfoot, near Manchester; Miss A. Wrigley, Tonge Lane, Middleton; T. B. Williams, Rochdale. Commended, F. Pittis, jun., Newport House, Isle of Wight; S. Smith, Northowram, Halifax; J. P. Bigg.

HAMBURGERS (Silver-pencilled).—Cup and Second, Sir St. G. Gore, Bart. Third, R. Fitton, jun., Turf Lane, Royton, Highly Commended, S. Taylor, Habbotshole, Windermerre; Viscountess Holmesdale; J. Preston, Allerton, near Bradford. Commended, A. K. Wood.

HAMBURGERS (Golden-spangled).—First, J. Roe, Hedfield, near Manchester. Second, T. Waring, Preston. Third, A. K. Wood. Highly Commended, Sir St. G. Gore, Bart.; N. Marlor, Denton, near Manchester; R. Hurst, Rochdale. Commended, H. E. Emberlin, Leicester; J. Ogden, Hollingwood; Commended, E. Tate, Leeds.

HAMBURGERS (Silver-spangled).—First, A. K. Wood. Second, Sir St. G. Gore, Bart.; Third, J. Fielding. Highly Commended, J. Fielding; J. Robinson, Vale House, near Garstang; Miss E. Beldon, Bingley, Yorkshire. Commended, J. Stephenson, Whitfield, Crompton; Rev. W. Serjeantson, Shrewsbury.

HAMBURGERS (Black).—First, Sir St. G. Gore, Bart. Second, R. Battersby, Howwood, Third, J. Clegg, jun., High Crompton, near Rochdale. Highly Commended, Miss E. Beldon; G. Lingard, jun., Selly Oak, near Birmingham; J. P. Fielding. Commended, W. Harrison, Gorse Hill, Heywood; C. Sidgwick, Keighley; L. E. Goodwin, Middleton.

POLANDS (Black, with White Crests).—First, J. Smith, West Lane, Keighley. Second, P. Unsworth, Lowton, near Warrington. Third, S. Farrington, Astly, near Manchester. Commended, P. Unsworth; J. Smith.

POLANDS (Any other variety).—First, Sir St. G. Gore, Bart. Second, Miss E. Beldon (Silver), Third, W. D. Seel, West Bank, Rochdale (Silver-spangled). Highly Commended, Miss E. Beldon (Gold); W. Sylvester, Hampden Kew, near Sheffield; J. Hinton, Hinton, near Bath (Silver); Commended, W. Sylvester (Golden); Mrs. Procter, Hull (Silver).

GAME (Black-breasted Red).—Cup, Sir St. G. Gore, Bart. Second, W. Webster, Whitwell, Chesterfield. Third, A. B. Dyas, Madley, Salop. Fourth, W. S. St. John, Darlington. Highly Commended, E. C. Gilbert, Penkridge; M. Athcock, Stowmarket.

GAME (Brown-breasted Red).—First and Second, J. Fletcher, Stone-rough, near Manchester. Third, J. Anderson, Ruthven House, Meigle, N.B. Fourth, S. Mathew. Highly Commended, Sir St. G. Gore, Bart.; J. Smith, Broder Hills, Grantham; A. Fenton.

GAME (Duckwings, and other Grays and Blues).—First, J. Fletcher, Second, J. Knowles, Old Trafford, Manchester. Third, Sir St. G. Gore, Bart. Highly Commended, Messrs. J. and A. Briggs, Slackbeck Farm, Rawdon. Commended, J. Goodwin, Bakewell, Derbyshire.

GAME (Any other variety).—First, J. Fletcher (Pile), Second, T. West, Eebleston, Lincs. Third, J. D. Newsome, Batley, Yorkshire (Black). Highly Commended, T. Whitaker, Melton Mowbray (Pile). Commended, Messrs. Bullock and Rapson, Leamington (White); H. C. Mason, Leeds.

GAME BANTAMS (Black Red).—First, Sir St. G. Gore, Bart. Second, C. W. Brierley, Third, J. W. Morris, Rochdale. Highly Commended, A. Fenton; G. Maples, jun., Waverley, Liverpool; R. E. Postans.

GAME BANTAMS (Brown Red).—First, Miss E. A. Crawford, Farnfield, Netts. Second and Third, D. Pares, jun., Cherdron, near Preston.

GAME BANTAMS (Any other variety).—Cup, R. Swift, Southwell, Notts (Duckwings). Second, R. E. Postans, Duckwings. Third, J. Crossland, jun., Wakefield (Duckwings).

BANTAMS (Gold or Silver Bright).—First and Second, M. Leno, Dumstrie (Gold-laced and Silver-laced). Highly Commended, J. and A. Briggs (Gold); T. Davies, Newport (Silver); C. Spary, Markate Street, Dumstrie (Gold). Commended, S. Farrington; R. Adams, Hindsworth (Silver).

BANTAMS (White, Comb-legged).—First, Sir St. G. Gore, Bart. Second, Rev. F. Tearle, Leicester. Highly Commended, C. W. Brierley; H. Draycott, Humberstone, near Leicester. Commended, Rev. F. Tearle; W. J. Cope, Barnsley, Yorkshire; H. Draycott.

BANTAMS (Bibels).—First, E. Hutton, Pudsey, Leeds. Second, T. Davies, Highly Commended, H. Draycott; Sir St. G. Gore, Bart.; Rev. F. Tearle.

ANY OTHER VARIETY.—First and Fourth, National Poultry Company (Limited) (Holland and La Fleche). Second, F. W. Zurlhorst (Sultans), Third, W. Wood (Malays). Fifth, J. D. Newsome (Cochin-China). Highly Commended, P. W. Storey, Daycross; F. W. Zurlhorst (La Fleche); Mrs. Wolferstan, Tamworth (La Fleche); J. Hinton (Malays); G. W. Brierley; National Poultry Company (Limited) (Holland); R. Hurst (Sultans); G. Hutter, Stillington, York (Malay). Commended, E. Pigeon (La Fleche); H. Savile (Silly Japanese).

DUCKS (Rouin).—Cup, Sir St. G. Gore, Bart. Second, T. Wakfield, Newton-le-Willow. Third, A. F. Bon, Highly Commended, J. K. Fowler, Commended, J. Nelson, Henton, Notts.

DUCKS (Aylesbury).—First, A. Pitts, Hoole Hall, Chester. Second and Third, Miss G. Leach, Greave, near Rochdale. Highly Commended, H. Jones, Denton, Aylesbury; J. Skinner, Maidon.

DUCKS (Any other variety).—First, E. Hutton, Second and Highly Commended, J. Jamison (Carolinas, Pintail, and Teal).

GESE (Any variety).—First, O. A. Young, Ditheld, Yorkshire (White). Second, J. K. Fowler (Foulouze). Third, Hon. Mrs. Arbuthnot (Mottled).

TURKEYS.—First, J. Smith. Second, Hon. Mrs. Arbuthnot (Cambridge, Wild American). Third, J. Wood.

SINGLE COCKS.

COCHIN-CHINA (Cinnamon or Buff).—First, G. F. H. Second, T. Wrigley, jun. Third, T. Wrigley, sen. Highly Commended, F. W. Zurlhorst; J. Horrocks; H. Tomlinson. Commended, W. Dawson.

COCHIN-CHINA (Any other variety).—First and Third, E. Truman.

Second, J. Wood (Partridge). Highly Commended, F. Crossley, Elland; E. Smith, Middleton, near Manchester. Commended, T. Stretch (Partridge).

DONKING (Any colour).—First, Viscountess Holmesdale. Second, W. Harvey, Third, J. Robinson, Vale House, Garstang. Highly Commended, R. P. Williams; J. White, Warley, North Allerton. Commended, Sir St. G. Gore, Bart.

SPANISH.—First, E. Brown, Sheffield. Second, Messrs. Burch & Boulter, Third, J. Hartley, Rochdale.

HAMMOUT (Golden-pencilled).—First, Miss E. Beldon. Second, J. E. Powers. Highly Commended, J. Robinson, Vale House, Garstang; Messrs. Burch & Boulter. Commended, Sir St. G. Gore, Bart.

HAMMOUT (Silver-pencilled).—First, Miss E. Beldon. Second, Sir St. G. Gore, Bart. Highly Commended, J. Rhodes, Acreington; J. Preston, Commended, J. Robinson, Vale House, Garstang; Messrs. Hindle and Funniss, Acreington; E. E. M. Roys, Rochdale.

HAMMOUT (Golden-spangled).—First, Mrs. J. Wright, Melton Mowbray. Second, Sir St. G. Gore, Bart. Highly Commended, Miss E. Beldon. Commended, J. Roe; A. K. Wood.

HAMMOUT (Silver-spangled).—First, S. Smith. Second, Sir St. G. Gore, Bart. Highly Commended, G. E. Hardman, Rawtenstall; J. Fielding; Miss E. Beldon. Commended, J. Robinson, Vale House, Garstang.

GAME (Black Red).—First, E. C. Monk, Fleetwood. Second, W. Phillips, Worcester. Third, Sir St. G. Gore, Bart. Highly Commended, J. Fletcher; C. W. Brierley; Sir St. G. Gore, Bart.; A. B. Dyas.

GAME (Brown Red).—Cup, J. Fletcher, Second, C. W. Brierley, Third, Sir St. G. Gore, Bart. Highly Commended, Hon. H. W. Fitzwilliam, Wentworth Woodhouse, Rotherham; Sir St. G. Gore, Bart.

PIGEONS.

The show of Pigeons was scarcely equal in quality to that of the poultry, although many good birds competed. In Single Pouter cocks Mr. Fulton was first with a White, indifferent in shape, and rather thinly covered in limb, a good Blue being second; but Mr. Harvey's highly commended White was much the best in the class, being fine in shape, with nicely covered limbs, and much longer in feather. Blue-Pouter hens were first and second; the former was very handsome, and the latter extremely inferior, being bare-shinned, with the legs placed on the body like stilts, and without any pretension to rose-pinion, or half-moon, in addition to a dingy colour. A very fine highly commended Black hen should have had first position. Carriers formed two good classes; very stout Black cocks and two extremely promising hens had the prizes. Tumblers had four classes, and the most noticeable were Mr. Oates's Blue Beards and Mr. Fulton's Almonds and Black Mottles, all of which deserved their positions in the prize list. Barbs were good, Mr. Robinson's wonderful Blacks having first place. In Oaks the first-prize pen (Whites) contained a hen much out of condition, being minus the feathers at the back of the head, the second prize went to good Blues. In Fantails and Turbits some of the best birds were unfit for competition. In Any other variety, Swiss Pigeons were first, Siberian Ice Pigeons second and extra second, the best pair taking the latter position, Jacobins third, and Isabels extra third.

The cup for the most successful exhibitor fell to Mr. J. Fielding, jun., of Rochdale.

It is with great regret we have the unpleasant duty of recording a villainous tampering with Pigeons, happily previously unknown at our Pigeon Shows. Prior to the judging several pairs of birds, including the best Turbits and Fantails, had been deliberately plucked, the entire frills of the former and the greater portion of the tail feathers of the latter having been removed, and on search being made the removed feathers were discovered concealed near the end of the pens. At a meeting of the Club the utmost indignation was expressed at this dastardly trick, and it was unanimously resolved to take immediate steps for the discovery of the offender, and with that view a reward of £10 was offered for such information as would lead to the detection of the guilty party. The birds belonged to Mr. Thackeray, Mr. Robinson, and Mr. Yardley.

POWTERS.—Cock, First, R. Fulton, Duke Street, Deptford. Second, J. R. Robinson, Nile Street, Sunderland. Highly Commended, W. Harvey. Hens.—First and Second, W. Ashforth. Highly Commended, H. E. Emberlin, Leicester; J. R. Robinson, Nile Street, Sunderland. Commended, J. Thackeray, Petergate, York; J. Fielding, jun.

CARRIERS.—Cock, First and Second, T. Colley, Sheffield. Highly Commended, J. Thackeray; F. Else, Baxwater, London. Commended, G. Ure, Dundee. Hens.—First, E. Else. Second, W. Massey, Fulford, York. Highly Commended, J. Fielding, jun.; G. H. Roberts. Commended, T. Colley.

FALDS.—First, E. E. M. Roys. Second, J. Thackeray. Highly Commended, J. Fielding, jun.

BEARDS.—First and Second, W. H. C. Oates, Resthorpe, Newark.

TUMBLERS (Almond).—First and second, R. Fulton. Highly Commended, J. Ford.

TUMBLERS (Any other variety).—First, R. Fulton (Black Mottled). Second, J. Fielding, jun. Highly Commended, J. J. H. Stockall, Liverpool (Red); G. Ure (Black Mottled).

PANTAILS.—First, F. Else. Second, E. E. M. Roys. Highly Commended, F. Else.

BARBS.—First, J. R. Robinson, Nile Street, Sunderland. Second, M. Bodley.

TURBITS.—First, H. Mapplebeck, Moseley, near Birmingham. Second, W. Pepper.

OWLS.—First, E. E. M. Roys. Second, J. Fielding, jun. Highly Commended, J. J. H. Stockall; J. Fielding.

NESS.—First, Rev. A. G. Brook, Ruyton XI. Towns, Salop. Second, C. Bulpin, Bridgewater.

TUMBERBES.—First, J. Fielding, jun. Second, E. C. Gilbert, Penkridge, Staffordshire.

EXTRAS.—First and Second, J. Fielding, jun.

ANY OTHER VARIETY.—First, E. Pigeon (Swiss). Second, F. Broemel

Lewisham, Kent (Siberian Ice). Extra Second, J. J. H. Stockall (Siberian Ice). Third, E. E. M. Roys (Jacobins). Extra Third, J. Fielding, jun. (Isabells). Highly Commended, C. Cowburn, Calls, near Leeds (Archangels); J. Thackeray (Black Muscovies); H. Yardley, Birmingham.

JUDGES.—*Intery*.—T. Chaloner, Esq., Chesterfield; J. Douglas, Esq., Worksop; J. Dixon, Esq., Bradford; R. Tegby, Esq., Fullwood. *Pigeons*.—F. A. Esquilant, Esq., Brixton; T. B. Tegetmeier, Esq., Muswell Hill.

KELSO POULTRY AND BIRD EXHIBITION.

The fifth annual Exhibition of this Society was held in the Corn Exchange, Kelso, on Wednesday, the 31st ult.

SPANISH.—First, A. Redpath, Edinburgh. Second, J. Hardie, Sorbie, Langholm. Third, Mrs. Noble, Kelso. Commended, Bowman and Fearon, Whitehaven. *Chickens*.—First, J. Anderson, Melrose. Second, J. Hardie. Third, A. Redpath. Very Highly Commended, W. Patterson, Langholm. Highly Commended, J. Hardie. Commended, E. Brown, Sheffield; T. Musgrove, Longtown.

DORKING (Coloured).—First and Third, Lord Binning, Mellerstain. Second, J. Elsworth, Glasgow. Very Highly Commended, W. Cheyne, Selkirk; Lord Binning; Mrs. Burns, Edinm. *Chickens*.—First and Cup, Lord Binning. Second, J. Elsworth. Third, J. Hardie. Very Highly Commended, D. King, Aberdeen. Highly Commended, M. Horniston, Mainbois; T. Y. Craig, Kirkcaldy. Commended, F. Parlett, Chelmsford.

BRAHMA POOTRA (Any variety).—First, Mrs. Waugh, Lochmaben. Second, C. Pease, Darlington (various). Third, —Rathie, San Fein. Very Highly Commended, E. Sherman, Chelmsford (Dark). Highly Commended, Miss H. Scott, Ancrum House; J. Steel, Kelso (Grey); Lady Marjoribanks, Lees. (Very good class.)

COCHIN-CHINA (Any variety).—First, W. R. Park, Melrose (Buff). Second, Mrs. Dickins, Cornhill House. Third, J. Walker, Knavesborough. Very Highly Commended, J. Green, Belford Hall; Bowman & Fearon (Partridge). Highly Commended, F. L. Roy, jun., Nenthorn (Partridge). Commended, T. Y. Craig (Buff).

GAME (Any variety).—First, J. Hardie (Black Red). Second, Messrs. Easton & Mabon, Jedburgh (Brown Red). Third, W. Hodgson, Darlington. Highly Commended, J. Brough, Carlisle; F. L. Roy, jun. (Duckwing). Commended, Lord Binning (Black Red); D. Broomfield, Kelso. *Chickens*.—First and Cup, W. Boyes, Beverley (Red). Second, J. Hardie (Black Red). Third, J. H. Macnab, Barhead (Brown Red). Highly Commended, Mrs. J. Turnbull, Jedburgh. Commended, H. Goodall, Kirkcaldy (Black Red). *Cock*.—First, J. Hardie (Black Red). Second, Messrs. Easton & Mabon (Duckwing). Third, W. Boyes (Red). Highly Commended, J. Brough. Commended, J. A. S. E. Fair, Gilliestongues (Black Red); F. L. Roy (Duckwing).

HAMBURGS (Gold-spangled).—First, A. Heatlie, Selkirk. Second, R. Dekson, Selkirk. Third, W. Dickson, Selkirk. Very Highly Commended, T. Musgrove. Highly Commended, J. Walker.

HAMBURGS (Silver-spangled).—First and Cup, J. Stewart, South Arthurine, Barhead. Second, J. U. Sommer, Jedburgh. Third, W. France, Crief. Very Highly Commended, J. Walker. Highly Commended, R. Tate, Green Roads, Leeds; F. L. Roy, jun. Commended, W. Cheyne. (Very good class.)

HAMBURGS (Gold or Silver-pencilled).—First, R. Burrow, Longtown (Golden-pencilled). Second, J. Walker (Silver-pencilled). Third, W. Bowe, Carlisle (Golden-pencilled). Very Highly Commended, W. R. Park, Melrose (Golden-pencilled); G. Walker, Selkirk. Highly Commended, T. J. Saltmarsh, Chelmsford (Silver-pencilled).

BANTAMS (Game).—First and Cup, F. L. Roy, jun. (Black Red). Second, W. Morris, Rochdale. Third, J. F. Lunn, Jedburgh (Black Red); Very Highly Commended, W. Cook, Highgate Hill, Kelso (Duckwings); A. Robertson, Burntisland, Fife (Duckwings); J. Walker; D. Broomfield; F. Parlett, Chelmsford (Game); G. Turnbull (Game); G. Manning, Springfield (Game). Highly Commended, W. Hodgson, Darlington; Messrs. Easton & Mabon. Commended, Mrs. Sherman, Springfield, Chelmsford; M. Ballantyne, Spronston (Duckwings). (Very superior class.)

BANTAMS (Any other variety).—First, W. Morris, Rochdale (Silver-laced). Second, J. Ness, Kirkcaldy (Gold-laced Sebright). Third, J. R. Jessop, Hull (Black).

DUCKS (White Aylesbury).—First, A. O. Swan, Bush, Jedburgh. Second, J. Fair. Third, Lord Binning. Highly Commended, Miss H. Scott, Ancrum House. Commended, W. Hood, Edginston Bigg.

DUCKS (Any other variety).—First, J. U. Sommer (Rouen). Second, W. Hodgson, Darlington (Rouen). Third, Miss H. Scott (Rouen). Very Highly Commended, J. Jennison, Manchester. Highly Commended, J. Jenkinson; H. Groen, Floors Castle (Rouen). Commended, J. Patterson, Floors Castle, Kelso (Rouen); T. C. Harris-on, Hull (Brown Call); G. Hall, Bowmont Forest (Rouen); F. Sommer (White Call).

TURKEYS.—First, J. Anderson, Melrose (Black Norfolk). Second, J. Hardie, (Cambridge). Third, Lord Binning (Cambridge).

DOZEN HEN'S EGGS.—Prize, T. L. Jackson, Bush of Ewes, Langholm. **COTTAGE PRIZES**.—First, A. Henderson, Dunip, Jedburgh (Dorking). Second, J. McMillan, Jedburgh (Minorca). Third, J. Fleming, Kelso (Game). Highly Commended, A. Purves, Mayfield, Kelso (Dorking); G. Mercer, Homdslow (Hamburghs); J. Jeffrey, Kelso (Duckwings). Commended, J. C. Turnbull, Bellingham (Game); T. Noble, Kelso (Spanish).

SELLING CLASS.

ANY VARIETY.—First, Rev. M. H. Graham, Maxton (Dorking). Second and Third, J. A. S. E. Fair, Gilliestongues (White Dorkings). Very Highly Commended, J. Murray, Kelso (Spanish); J. Walker (Silver-spangled); Lord Binning (Scott Grey); R. Dickson (Gold-spangled); Easton & Mabon (Game); J. Towns, Longtown (Gold-pencilled Hamburgh). Highly Commended, J. Hardie (Silver Dorking); T. J. Saltmarsh (Golden Sebrights); F. L. Roy (Silver-spangled Hamburghs); T. Patterson (Rouen Ducks); W. Mattingly, Chelmsford (Buff Cochins).

SWEPESTAKES FOR SINGLE COCKS.

DORKING (Any variety).—First, J. Hardie (Silver). Second, J. Harvey, Jedburgh.

BANTAM (Any variety).—First, D. Broomfield (Game). Second, A. Skin-

ner, Falkirk. Very Highly Commended, F. L. Roy (Black Red); Miss J. Steel, Kelso (Game); G. Turnbull (Game). Highly Commended, C. Pease; F. L. Roy (Black Red and Black). Commended, W. Murray, Kelso (Duckwing); T. Boyd, Kelso (Black); J. Young (Black Red); J. Harvey (Black Red). (Extraordinarily good class.)

PIGEONS.

CARRIERS.—First, E. Brown, Sheffield. Second, J. R. Robinson, Sunderland. Very Highly Commended, H. Allsop, Birmingham. Highly Commended, H. Yardley, Birmingham. (Very fine class.)

TUMBLERS (Any variety).—First, J. R. Robinson. Second, E. Brown (Almonds). Very Highly Commended, R. Irving, Langholm; H. Yardley. Highly Commended, H. Yardley. Commended, R. Irving. (Very good class.)

FANTAILS.—First, J. Grant, Edinburgh. Second, W. R. Park, Melrose. Very Highly Commended, W. R. Park; J. Campbell, Langholm. Highly Commended, J. R. Jessop. Commended, H. Yardley.

POWTERS.—First, J. R. Robinson. Second, J. Grant. Very Highly Commended, J. Grant. Commended, J. E. Spence, Musselburgh.

JACOBS.—First, R. Thomson, Kendal. Second, G. Yule, Mellowlee (White). Very Highly Commended, P. A. Renwick, Kelso. Highly Commended, A. Ormiston, Kelso. Commended, J. G. A. Spence (Yellow).

BARRS.—First, R. Thomson. Second, R. Davidson, Jedburgh. Very Highly Commended, J. R. Robinson; H. Yardley.

TURBITS.—First, G. Yule (Red). Second, W. R. Park (Blue). Very Highly Commended, F. Keir, Edinburgh (Yellow); R. Thomson. Highly Commended, R. Thomson. Commended, G. Yule (Blue). (A splendid class.)

ANY OTHER VARIETY.—First, H. Yardley. Second, G. Yule (Nuns). Very Highly Commended, J. Campbell (Magpies); E. Brown (Swiss). Highly Commended, H. Spence, Edinburgh (Black Magpies). Commended, F. Sommer, Jedburgh. (A good class.)

BEST PAIR (Any variety).—First, P. A. Renwick (Tumblers). Second, G. Gibb, Kelso (Turbits). Very Highly Commended, P. A. Renwick (Turbits). Highly Commended, W. Steel, Kelso (Blue Dragon).

CANARIES.

DONS (Yellow).—*Hen*.—First, W. Tinline, Galashiels. Second, J. Kemp Galashiels.

DONS (Buff).—*Cock*.—First, J. Walker, Kelso. Second, J. Bannister, Galashiels. Highly Commended, J. R. Thomson, Hawick. Commended, J. Kemp. *Hen*.—First, R. Paterson, Melrose. Second, W. Hardie. Highly Commended, J. Blackie, Jedburgh. Commended, Miss Clay, Kerehesters.

BEST COCK OR HEN.—Prize, W. Tinline (Yellow Don Hen).

BELGIANS (Yellow).—*Cock*.—First, J. Aitken, Kelso. Second, A. Rutherford, Kelso. Very Highly Commended, J. Jeffrey, Kelso. Highly Commended, J. Kemp. Commended, G. Trotter, Kelso. *Hen*.—First, J. Dryden, Kelso. Second, P. Cockburn, Gordon. Highly Commended, G. Laidlaw, Galashiels.

BELGIANS (Buff).—First, G. Laidlaw. Second, J. Kemp. Very Highly Commended, J. Aitken. Commended, J. Blake, Kelso. *Hen*.—First and Second, J. Marshall, Galashiels. Highly Commended, A. Wood, Galashiels. Commended, W. Tinline.

BEST COCK OR HEN.—Prize, G. Laidlaw (Buff Belgian Cock.)

FLECKED CANARIES.

BELGIAN (Yellow).—First and Second, P. Cockburn, Gordon. Highly Commended, A. Cockburn, Gordon. Commended, J. Archibald, Melrose; J. Dryden, Kelso.

BELGIAN (Buff).—First, W. M. Mein, Newstead. Second, A. Rutherford. *Don* (Yellow).—First, G. Craig, Kelso. Second, G. Park, Galashiels. Commended, R. Rutherford, Jedburgh; A. Brown, Kelso; J. Burnett, Kelso; G. Craig.

Don (Buff).—First, J. Dickson, Edinburgh. Second, Miss Clay. Commended, J. Archibald; J. R. Thomson, Hawick.

SWEPESTAKES.

CAGE OF NOT LESS THAN FOUR BIRDS.—First, J. Dryden. Second, J. Aitken. (Any variety). Commended, G. Laidlaw.

PAIR OF CANARIES (Any variety).—First, J. Jeffrey (Belgian). Second, A. Ferguson. Very Highly Commended, J. Walker; G. Craig. Highly Commended, A. Bulman, jun. (Dons); T. Reid (Belgian). (Very good class.)

BEST PERCHING BIRD.—Prize, G. Rutherford. Very Highly Commended, J. Walker (Goldfinch).

HALIFAX POULTRY SHOW.

The first annual winter show of Poultry, Pigeons, Rabbits, and Canaries was held in the Temperance Hall, Halifax, on the 3rd inst. In number of entries the Show was more successful than was anticipated, seeing that the show of the Poultry Club was held at the same time. The classes for *Game Fowl* contained some excellent birds, the first prizes in each case being given to Brown Reds and the second to Black Reds. The Spangled *Hamburghs* were poor, but the Pencilled were good. It was a great mistake of the Committee to class Gold and Silver together, as otherwise a large entry would have rewarded their endeavours. The winning pens in *Spanish* were very good, but the rest were not worth notice. In *Game Bantams* the winners were Duckwings and Reds respectively; and in other varieties of Bantams, Blacks and Golden-laced. Good *Brahmas*, *Dorkings*, and *Black Hamburghs* graced the Variety class. *Pigeons* had but one class, which was well supported with good specimens of Carriers, Powters, Dragons, Tumblers, &c.; while *Rabbits* had four classes and but few entries; and some excellent Himalayas were exhibited.

The room was not well suited to the purposes of a poultry show, and in some parts the birds could scarcely be seen.

SINGLE GAME COCK.—First, J. Gelherd, Kendal. Second, H. Hemingway, Shelf near Halifax. Highly Commended, J. Dyson, Queen's Road, Halifax; J. Wilson, Ovenden, near Halifax; G. Settle, Bradford; H. Wood, Bradford.

GAME.—First, H. C. Mason, Drighlington. Second, G. Noble, Staincliffe, Dewsbury. Highly Commended, A. Hodgson, Ilmworth, near Halifax.

HAMBURGH (Gold or Silver-spangled).—First, S. & R. Ashton, Mottram.

Second, J. Preston, Alorton, Bradford. Highly Commended, S. C. Noble, Strickland Gate, Kendal.
HAMPTON (Gold or Silver-pencilled).—First, Mrs. Holmes, Manor Heath Lodge, Second, J. Frost, n. Highly Commended, Mrs. Holmes; E. Hemingway.
SPANISH Black.—First, J. Thrush, Bradford, Second, J. Marchant, Hunsen Lane, Halifax. Highly Commended, J. Marchant.
COCHIN-CHINA.—First, J. Wade, Copley Mills, Second, H. Crossley, Brookfield. Highly Commended, H. Crossley.
BANTAM Game.—First, J. W. Thomas, Queen Road, Halifax. Second, G. Noble. Highly commended, C. Ashworth, Thomas Street, Halifax.
BANTAMS (Any other variety).—First, E. Hutton, Pudsey near Leeds. Second, J. Walker, Bellon Lane, Halifax. Highly Commended, J. W. Thomas, Queen's Road, Halifax; W. Walsbaw; S. A. R. Ashton.
SINGLE GAME BANTAM COCK.—First, J. W. Iker, Second, C. Ashworth, Thomas Street, Halifax. Highly Commended, J. Walker; T. C. Harrison, Beverly Road, Hull.
SINGLE GAME HEN.—First, J. Dyson. Second, J. Hodgson, Bowling Old Lane, Bradford. Highly Commended, J. Pickles, Mytholmroyd.
ANY VARIETY NOT PREVIOUSLY MENTIONED.—First, J. H. Pickles, Bridge-royd near Todmorden. Second, L. J. Crossley, Willow Hall, Halifax. Highly Commended, M. M. S. Denton, Stainland near Halifax; F. Clayton, Bradford; W. H. Wheeler, Nottingham.
PIEONS (Any variety).—First, C. Gawburn, Cotts, Leeds (Carriers). Second, W. Hughes, Leeds (Abroad Tunnellers). Highly Commended, T. Marchant (Trimmers); S. Wade, Ovenden, near Halifax (Turbits and Jacobins); W. Hughes, Powtess; C. Cole, Bowling, near Bradford.
RABBITS (Largest Breed).—First, J. Fleming King's Cross Road, Halifax. Second, A. Crossley, *Spotted*. First, A. Crossley. Second, W. Walker. *Any colour.*—First, J. Warden, Fleece Inn, Halifax. Second, J. Fleming. *Foreign.*—First, W. Walker, Bothery Street, Halifax. Second, M. Huns- worth, Church Street, Halifax.

CANARIES.

BELGIAN (Cock).—First, W. Bottomley, Green Lane, Halifax. Second, T. Firth, Ovenden near Halifax.
YELLOW MARKED (Cock).—First, W. Wilkinson, Bank Bottom, Southowram. Second, T. Walker.
BEFF-MARKED (Cock).—First, T. Firth. Second, W. Wilkinson, Halifax.
LIZARD (Cock).—First, W. Bottomley. Second, J. Wilson, Silver Street, Halifax.
COCK (Any other variety).—First, W. Bottomley. Second, T. Firth.
HEN (Any variety).—First, J. Wilson. Second, W. Bottomley.
 The Judges were J. W. Thompson, Esq., Southowram; and Mr. R. Tate, Leeds.

DERBY EXHIBITION OF BIRDS, &c.

We were again gratified with a visit to the Bird Show, held this year in the Temperance Hall, Curzon Street, which was kept open from the 25th to the 27th ult. The Exhibition on the whole was a great success. The following were the awards:—

CANARIES AND MULES.

NORWICH (Clear Yellow).—First, G. F. Welch, Derby. Second, R. Mackley, Norwich. Third, J. Bexson, Derby. Highly Commended, S. Lunting, Derby; G. Moore, Northampton. Commended, G. Collinson, Norwich.
NORWICH (Clear Buff).—First, G. F. Welch. Second, W. Walter, Win- chester. Third, E. Cole, Derby. Highly Commended, W. Walter. Com- mended, R. Mackley.
NORWICH (Variegated or Marked).—First, R. Mackley. Second, A. G. Barnesby, Derby. Highly Commended, G. Collinson. Commended, E. Orme, Derby.
BELGIAN (Clear Yellow).—First, J. Pool, Sutton. Second, J. Hayes, Sutton. Third, S. Bunting. Highly Commended, J. Hayes. Commended, J. Pool.
BELGIAN (Clear Buff).—First, W. Vic, Derby. Second, G. Corbett, Birmingham. Third, J. Hayes. Highly Commended, W. Phillips, Bas- ford. Commended, J. Pool.
BELGIAN (Variegated Yellow).—First and Second, J. Pool. Highly Com- mended, G. Corbett. Commended, J. Martin, Belper.
BELGIAN (Variegated Buff).—First, W. Phillips. Second and Highly Commended, G. Corbett. Commended, J. Hayes.
BELGIAN (Crested).—First, H. Ashton, Manchester. Second, A. G. Barnesby.
BELGIAN (Tied or Marked).—First, J. Pool. Second, G. Corbett. Highly Commended, J. Bexson. Commended, J. Hayes.
LIZARD (Golden-spangled).—First and Third, J. Hayes. Second, H. Ashton. Highly Commended, G. Harrison, Canterbury. Commended, W. L. Chapman, Northampton.
LIZARD (Silver-spangled).—First, J. Hayes. Second, G. Cummings, Gloucester. Third, H. Ashton. Highly Commended, H. Ashton. Com- mended, A. I. Ben, Derby.
GOLDFINCH MULE (Jumbo).—First, H. Ashton. Second, W. Walter, Third, J. Hayes. Highly Commended, R. Mackley. Commended, W. Walter.
GOLDFINCH MULE (Mealy).—First, H. Ashton. Second, W. L. Chapman, Third, W. Walter. Highly Commended, R. Mackley. Commended, W. Walter.

ANY OTHER VARIETY.—First, H. Ashton (Linet Mule). Second, R. J. Troake, Bristol. Greenfinch and Goldfinch Mule. Highly Commended, G. Moore (Siskin Mule). Commended, W. Gamble (Green Linnet Mule).
NORWICH (Jaquet, egg of six).—Prize, R. Mackley. Highly Com- mended, J. Wynn. Commended, W. Walter.
BELGIANS (Yellow, egg of six).—W. Phillips. No competition, and prize withheld.

BRITISH BIRDS.

BULLFINCH.—Prize, G. Crewe, Breadsall. Highly Commended, A. W. Fooker, Liverpool. Commended, H. G. George, Littleover Hill.
GOLDFINCH.—Prize, Capt. C. H. Fisher, Stroud, Gloucestershire. Highly Commended, H. Ashton. Commended, A. W. Bookler.
LINNET (Brown).—Prize, S. Reynolds, Derby. Highly Commended, S. Stator, Derby. Commended, G. Cummings.
SKYLARK.—Prize, W. Walter. Commended, G. Cummings.

BLACKBIRD.—Prize, H. Nicklinson, Derby. Highly Commended, A. G. Barnesby.
THRUSH.—Prize, T. Morton, Derby. Highly Commended, J. Bexson. Commended, T. Keys, Derby.
SPRINGER.—Prize, W. Morris, Hilton. Highly Commended, R. Mackley. Commended, G. Boone, Derby.
ANY OTHER VARIETY.—Prize, G. S. Crewe (Green Linnet).

FOREIGN BIRDS.

COEATOO.—Prize, R. H. Cox, Derby.
GRAY PARROT.—First, T. Bidolph, Derby. Second, T. Eyre, Derby. Highly Commended, Miss C. Crewe, Breadsall.
PALLO (Green).—First, A. W. Bookler. Second, R. H. Cox.
PARROT'S GRASS.—First, H. Ashton. Second, Capt. C. H. Fisher. Highly Commended, W. Walter.
EXTRA.—First, F. Thompson, Derby. Second, H. Ashton. Highly Commended, W. Walter.

BANTAMS.—Prize, W. Fiv, Derby. Highly Commended, W. Madeley, Derby. Commended, N. Barber, Derby; B. Wright, Alderear Hall, Notting- ham.

RABBITS.—Prize, W. Holmes, Derby. Highly Commended, W. Holmes. Commended, W. H. Holmes.

PIEONS.—T. Worthington, Esq., Derby; Mr. Carnally, Nottingham; and Mr. Lord, Oldham.—Geo. J. Barnesby, *Do do*.

EXPENSES AND RETURNS OF POULTRY KEEPING.

I SEND you a statement of the expenses of keeping a stock of poultry in the past year. I should be very much obliged to you if you will give me your opinion on the subject, as I want to know whether they are kept extravagantly, or, as I hope, at a tolerably reasonable expense. The aviary birds consist of Pheasants, and different varieties of fancy Pigeons; and the fowls are Hamburgs, Game, and Nankin Bantams. The Cochins and Ducks are entered separately. I counted up the chickens as chickens till they were really, as I considered, as expensive in their food as large fowls. I added up, as you will see, the numbers fed every week, so as to make out my monthly number. If you can suggest any alterations I should be very grateful to you.

NUMBER OF FOWLS FED IN 1865.				
	Cochins.	Fowls.	Ducks.	Aviary Birds.
January	35	210	41	73
February	39	245	45	91
March	29	180	28	76
April	28	168 126	28	81
May	28	144 254	28	80
June	35	177 350	35	100
July	48	226 393	112	88
August	44	195 388	94	82
September	72	365 459	67	80
October	88	265 chicks now	50	78
November	90	283 counted as	20	69
December	33	219 as adults.	28	84
Totals..	507	2426 1284	576	982

Poultry and eggs	14	10	10
Poultry and eggs sold	16	11	9
Present value of stock	9	7	6
	£40	10	1

You will perceive in this statement, that beyond occasional presents, no charge is made for labour. The fowls being cared for by the woman and myself, I hardly knew at what rate of wages to put him down, the fowls by no means taking up his whole time.

If you will kindly give me an answer as to whether you think my expenses for food are more or less than they should be, I shall be very glad. The extra expenses and stock-buying, of course, vary from year to year. I should add, that in valuing my stock at the close of the year, I put them at far under cost price, knowing that if I sold them I probably should not receive what I gave for them.—C. E.

We are very much obliged for the statement you have sent us. It interests us much. We cannot point out any possible reduction. The only change we should like to see would be a separation of the expenses incurred for small birds and poultry. At present from blending the two, the price per head seems lower than we have ever been able to accomplish in our experience. We think you may put the labour at 1s. per day. We should also like to know whether the birds have

* Includes wickerwork, pans, travelling expenses, presents to poultry man.

any harndoor or accidental food. We shall be glad of any further details as it has long been our opinion that poultry-keeping may be almost reduced to a system as to its expenditure, and that fowls may have the proper allowance served out weekly as easily as it is done for horses, and with the same result of health and high condition. The want of reliable statistics misleads some, and discourages others.]

VULTURE HOCKS—TRIMMING.

THE remarks of "CLERICUS" have somewhat forestalled what I myself had been intending to say on this subject. I am utterly astonished at the reply of "one of our most able Judges," that the vulture hock is a recent introduction. You have hit the date more correctly, I imagine, at 1850, and I can myself bear you out, as I had some of Sturgeon's birds soon after that date, and I should say that vulture hock dates from the introduction of Cochin fowls. Before that time all our known breeds of poultry were naked-hocked birds; Dorkings, Spanish, Game, Malay, Polish, had this in common, whilst the vulture hock was found only in some of the booted Bantams, very seldom seen, and certainly not the source that could have given it to the Cochin. Whence, then, did it come, if not with the birds themselves? If we look at the original plates of "The Poultry Book" we find the hock feathers decidedly projecting; and in the description given of the cock I find:—"Thighs wide apart, &c., feathered quite down to the hock or knee, and the feathers even projecting beyond it, as in the Falcon;" and yet this is of *recent* origin!! Cochins and Brahmans have certainly this in common, that the thighs are fluffy, and the feathers very numerous as compared with other breeds. This abundance of feathers in all good specimens of these breeds should hide the hock joint from view, except on the inside. This has always been the case in good specimens. Soon it was found that the actual falcon hocks—the feathers reaching some inches behind the joint—were accompanied by profusely-feathered legs; and as heaviness of feathering is an essential in both these breeds, the actual falcon-hocked birds were probably used for breeding, and I apprehend there is no good breeder of either Cochins or Brahmans that wishes for naked-hocked birds, and none, I fancy, who would object to the soft feathers projecting half an inch or more behind and around the joint; for myself, I should not object to an inch, provided the feathers were soft and curving inwards. The rage against the moderate vulture hock is recent, if you like, and like all extremes will do, nay, is doing harm. I have quite recently had a Brahma cockerel sent me on approval. Well, the first-rate breeder to whom he belonged evidently had the fear of the hock before his eyes, and the hock joint was not hidden from view when looked at posteriorly; as a consequence of this paucity of feathers at the hock, the upper part of the leg was comparatively poorly feathered.

There are certain characteristics of breeds, and most assuredly the covered hock joint is the property of Cochins and Brahmans, as opposed to Malays, Dorkings, Game, Spanish, &c. In the other breeds the hock is bare, the joint fully exposed, and it coincides with the general close-feathering of these breeds. As it appears to me, to disqualify birds because vulture-hocked is extremely unjust, and I quite agree with you that the vulture hock is necessary in moderation. But if this defect when stiff can, by a dishonest exhibitor, be remedied by pulling, and in this condition be "very difficult of detection," surely it is an additional reason for not being so strict on the point. It would be very interesting to myself, and I doubt not to many other breeders of feathered-legged poultry, if the able Judge before alluded to would kindly describe what the leg ought to be. I myself should prefer hock feathers, projecting from half an inch to an inch over the joint, provided the feathers were soft. The stiff-feathered hock I do not like, but commend me to the feathering of leg that always attends it. The remarks of "CLERICUS" are much to the point, and I hope will assist in saving the best birds from being ruined.

The trimming alluded to by the Judge cannot be detected except on very close and careful examination of each specimen, and when the duties of a Judge under such circumstance would be completed in a close competition, it would be hard to say.

There are certainly some eccentricities in poultry-judging. A spriggy comb is a disqualification in Spanish or Cochin, but you may trim and remove it. I have bred many a first-rate Poland but for the spriggy combs. No good Poland wants a comb, although he has more hair, or rather feathers, on his

head than other breed, and might be supposed to want it more. Well, may I remove these? If it is allowable to remove sprigs from the other combs where they are not wanted, surely it is allowable to remove it in Polands. You may trim a Game face, but woe betide you if your pincers should try to improve a Spaniard's visage. The sooner the regulation against trimming is removed by committees the better, for at present it is used in an arbitrary manner.

Since writing the above I have read with great pleasure the remarks of "JESTITA," and I heartily thank him or her for them. The exact point is touched in these words: "If what is sanctioned one year may be reprobated the next, what ground of security have we to stand upon?" And if we are to leave our pets to the fancies and vagaries of every person who is styled a judge, we shall never know what to aim at! Nay, we are not certain that in a year or two the very opposite may not be considered requisite, and the shifting of the points to be sought after is fatal to success. I trust your own remarks and those of other exhibitors will show the judges that we do not intend to have our birds injured to suit their fancies. I can recollect in the early Brahma days a judge, who shall be nameless, disqualifying one of my Brahma cocks because he was pea-combed. Well, suppose exhibitors had set to work to breed single-combed birds, would not one of the great beauties of the breed have been lost? Save us from our friends if these are all the kindnesses they can show us!—Y. B. A. Z.

DRAGOON PIGEONS.

My attention was called the other day to a letter which appeared in your valuable paper of December 19th, from Mr. John Percivall, of Birmingham, relative to the judging of some of the Pigeon classes at the late Birmingham Exhibition. I regret that so much time has passed since the insertion of that letter; as many of your readers have, doubtless, taken for granted that the whole of Mr. Percivall's unanswered letter was correct. Mr. Percivall's opinion as a breeder of this very beautiful variety of Pigeon should certainly be taken notice of, and, henceforward, we must at least thank him for telling us what a good Dragoon should not be. I am, however, sorry to say that I think his letter has unjustly influenced many fanciers who once possessed good birds of this type, but who have since discarded them on account of what Mr. Percivall considers a blemish, and to use his own language, sufficient to exclude them from taking a prize—viz., the lower part of the back being white, or their being, as it is termed, "white-rumped." I must here admit, that since the publication of Mr. Percivall's views, I have become possessed of some very handsome birds having the white patch he protests against strongly marked, which, but for that gentleman's opinion, I should have been unable to obtain. I feel convinced that the remarks he has made upon this subject, if left unanswered, would be detrimental to the fancy, and calculated to make a rare and useful variety of Pigeon still more scarce, by weeding from its numbers the most beautiful of their kind; and it is for this reason that I feel prompted to say a few words upon the subject.

Had Mr. Percivall argued in favour of drawing a line of distinction between the Dragons and their very near relatives the Carriers, instead of bringing them nearer together (as he undoubtedly does, by admitting only birds of a uniform colour), he might, perhaps, have supplied a want long felt by the fancy.

Dragoons, or Dragons, were unmistakably inferior Carriers; and the Blues, Yellows, and Whites, being unable to compete with the Blacks and Duns, have, most properly, had another name assigned them, and by careful and judicious breeding are now more dissimilar than they were years ago. They possess all the beauty and symmetry of form of the Carriers, without that preponderance of wattle which so frequently makes them appear ugly, though it is the chief characteristic of the latter. Having thus adopted another name for these birds, and worked for different points to render them more unlike—to detach them, as it were, from the Blacks and Duns, and make them worthy their new name, is, I think, what the Dragoon breeder has striven for: and, therefore, to follow Mr. Percivall and his fancy would be to certainly retrograde, instead of progress nearer to perfection.

I contend that the white-rumped Blue Dragons are a purer blue, the bars a deeper black, the neck of a better metallic lustre, the eye a brighter orange, and free from the dark circle round the iris, and altogether forming a better contrast than those of a darker or more sombre colour. I am not praising

the white-rumped birds because I have none other. I have nearly equal numbers of each, though I believe there is a majority of those with the white badge, because, as a rule, I find them the best for the reasons I have mentioned.

I would ask Mr. Percivall, through your pages, whether he would in a like manner discard the white-rumped Blue Owls, Runts, Antwarps, Powders, &c.? If so, I think this wholesale expulsion of beautiful birds from our shows will make sad havoc amongst their respective varieties. Even the Blue Rock Dove would almost be extinct, if the same slaughter could be made amongst them as he would make in the cultivated varieties.

Mr. Percivall says that he exhibited a pair of Blue Dragons at the late Birmingham Show. I believe the pair he alludes to claimed my special admiration, and were, in my opinion (as expressed at the time) the best pair in the Show, though not solely on account of their being minus the white rump. They possessed other properties or points, which, to my mind, set them above those they competed with. These, Mr. Percivall says, were honoured with a very high commendation; but, upon referring to the catalogue of the Birmingham Show, I find Mr. Percivall is credited with having taken the second prize, and his brother, Mr. James Percivall, of London, with the very high commendation. Is this a misprint? How are we to know to whom the birds really do belong? I know that both entertain the same notion with regard to the white rump being a defect; and I must say, whichever it was who exhibited the pair taking the second prize, that it either showed a great want of judgment in pairing for exhibition two birds so unequally matched, one possessing a mark, as Mr. Percivall himself says, quite sufficient to exclude it from prizetaking, or else it plainly evinced a scarcity of blue-rumped birds. Mr. Percivall acknowledges the justice of this award, but goes on to complain that the first prize was given to him for Archangels, because unequally matched, one bird having pearl, and the other gravel eyes.

In conclusion I ask, Is it consistent for Mr. Percivall to rail against the judging, or to set up a standard of excellence, when he, or his brother, or both, send for competition a blended bird in each pen, and expect to be rewarded upon the merits of either?—A DRAGON BEE-LIEVER.

REGICIDAL ATTACKS BY BEES.

I AM glad to see that Mr. Lowe has returned to this subject, and, in the hope of assisting in the investigation of what still appears to me a most extraordinary and very unsatisfactory chapter in the natural history of our little favourites, I purpose stating briefly the conclusions at which I have myself arrived, pointing out, at the same time, in what respects my views either coincide with or differ from those propounded by Mr. Lowe.

Regicidal attacks by bees may, I think, be divided into three classes:—

1st, Those in which a matron is imprisoned by her own children.

2nd, Those wherein the regicidal frenzy is set on foot through the introduction of stranger bees by the apianian.

3rd, Those in which a juvenile monarch is attacked by her worker sisters before she commences egg-laying.

Instances of the first class, in which a matron is assailed by her own children, seem to be comparatively rare, nor do they often come under the direct observation of the apianian; when they do occur, however, they appear to be inevitably fatal. A queen may possibly survive several initiatory attacks, but these are repeated at uncertain intervals, until at last she succumbs. In such cases, and in such only, can I indorse Mr. Lowe's conclusion that a queen once imprisoned forfeits all regard from her subjects, and that, therefore, interference on the part of the apianian can scarcely lead to any good result.

Cases of the second class, in which the regicidal frenzy is set up by the introduction of stranger bees through the manipulations of the apianian, are, of course, equally rare in well-managed apiaries, but, when such instances do arise, experience justifies me in declaring that the best results may be hoped for from prompt and judicious intervention; * since, if the hapless queen can but be kept alive in a queen-cage within the hive itself until the regicidal mania has abated, she will

* Mr. Lowe's mishap with his Lignum specimen is a sufficient warning against too rashly liberating imprisoned queens from the open air, as stated by me in "our Journal" of the 29th of September last. A number of our readers may be previously dismissed, but the bee-keepers should only be ventured upon within-doors, where the queen may be readily recaptured in the event of her taking wing.

then be well received by her whilom rebellious subjects, and, no matter how furious the attack may have been, she will be no more liable to a repetition of it than if it had never occurred.

Although the third class, in which young queens are imprisoned before they have entered upon the duties of oviposition, appears never to have been witnessed by Mr. Lowe, it is in reality by far the most common form of regicidal attack among bees, and is, moreover, very frequently fatal. In these cases, also, I have found by experience that intervention on the part of the apianian may often be beneficially resorted to whenever the danger is perceived in time. Although the attack may be repeated more than once, it is not even then necessarily attended with a fatal result; and if by the assistance of the apianian, or by her own unaided tenacity of life, the juvenile but distressed monarch can only last out until she begins egg-laying, her subjects thenceforward appear as heartily loyal as if she had never been incarcerated.

In conclusion, I may observe, that whilst Mr. Lowe declares himself unable to indorse my opinion that the imprisonment of a young queen by her worker sisters can be characterised as a regicidal attack, he totally ignores the fact that I have supported this opinion by relating three several instances which have come under my own observation, and in which the incarceration of such queens by their workers has been attended by fatal results, as well as by the evidence of my distinguished German correspondent, who states that he has frequently had young queens imprisoned and killed on their return from successful wedding flights. According to Mr. Lowe's views our verdict in all these cases should of course be "Killed by kindness;" but from this conclusion I for one must entirely dissent, and would record my unhesitating conviction, founded on considerable experience and many opportunities of judging, that in all cases, and under all circumstances, whenever a queen, either old or young, is imprisoned by workers, her life is invariably in great jeopardy, and that no such thing ever occurs amongst bees as what may be termed the "friendly arrest" of a queen.—A DRAGON-BEE LEE-KEEPER.

* Vide Nos. 195 and 205 of "Our Journal."

OUR LETTER BOX.

INCUBATOR *G. L. R.*—That which you first name we believe is the best at present in use. There is no book on the subject. Directions are furnished with each incubator by the makers.

DISTINGUISHING AYLEBURY DRAKES (*G. L. R.*)—The drake has always a curl in the tail when in full plumage; but as it may be pulled out, we will give you another means of knowing the sex. The drake is generally larger than the Duck. There is no doubt of the four Ducks doing well with the drake; but we do not think you will be pleased with the cross between the Aylebury and Pouter. Both breeds are very handsome when pure, and give undoubted proof of being a defined species; but the cross produces only a pidd, brown-and-white, common-looking bird, with nothing to distinguish it from the ordinary Duck of a farm-yard. Ducks do not like roosting in a house of any kind; it is against their nature. Wild Fowl roost on the water, and tame Ducks like to sit on the bank, or in a fern-yard to take up their own quarters. You may ascertain the sex of Ducks by taking the bird by the pinion of the wing; the Duck quacks, the drake gives a kind of hoarse hiss. Sometimes they are long before they will make any noise. It then becomes necessary to hold them off the ground. If you persevere in this, with a little patience, you will always succeed.

HENS NOT LAYING (*BROOKING, BARR, C.*)—Your hens will not lay so early this year as last. They were then pullets; and such lay earlier the first year than afterwards. We do not think the breed has so much to do with early as with late laying. The non-sitters lay much later in the year than those that have reared their broods. They will lay as many eggs without a cock as with one; but they never do so well, and generally take a deal sort of fanciness in the present instance. We believe they eat each other's feathers. They are heated, and you will do well if you allow them to run in the garden every day. The scraps of green food and the insects they pick up will do them good. Let them have a good heap of dry dust and another of bricklayers' rubbish in their house. By dusting in the first they destroy parasites, which often induce them to pick their feathers; the second supplies them with shell for the eggs. Nothing is better for them than lime and scraping or grit. We think that if you will do this, and put a cock with them, they will do better. Do not depend too much on potatoes for food, they are not favourable to egg-producing. They should not be kept in the hen that lays double or triple-yoked eggs, and that does so best year, will probably always do it. Such are never long-lived birds. If you cure such a nest (it is as you complain of, if the first appearance of a bare spot is rubbed with compound sulphur ointment).

LETTERS FOR PAGES *B. T. C.*—Buttermilk is given to pigs with advantage in every instance that we know of, except one, and that was where the practice was to salt the grama, and of course it was unfit for use until mixed with meal and given to the pigs in that condition alternately with other food. We do not recollect of the complaint you mention being reported in any of the dairy districts that we have been in; but there is one very like it, to the effect that "When I starve a dog, while it will hold a hog," and we have seen truth in the truth of the axiom. Buttermilk is freely partaken of by the working classes in the western cheese counties.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 45.4; and its night temperature 30.8. The greatest heat was 59, on the 16th, 1863; and the lowest cold 0, on the 13th, 1855. The greatest fall of rain was 0.50 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

REMOVING PLANTS TO DIFFERENT SOILS.

MR. Fish alluded to a fact which, somehow, has never yet received so much attention from the flower gardener as it ought, although agriculturists have for some generations been alive to its value.

Mr. Fish justly calls attention to the propriety of now and then exchanging plants or cuttings, and cites an instance in which some cuttings which he had from a neighbour showed much greater vigour than some of his own that were treated in exactly the same manner, and he attributes their doing so to the sole cause of his own being to a certain extent worn out or tired of their quarters. Now this is a subject of great importance, and the judicious application of the facts stated may no doubt save some of the old popular favourites, which are threatening in some cases to leave us entirely; while amongst those that may be still regarded as in their prime, improvement may be effected by the change, or at all events deterioration prevented or delayed.

Hitherto the common practice has been to retain a plant or variety until it is superseded by something better, when it is discarded; but such a course is not always a correct one. A variety of plant requiring re-propagation every year might be very good in 1856, while something better may be seen in 1866 than it is at that time; but has the first not deteriorated during that period from having been kept so long in the same place? In fact, has not the theory of breeding in-and-in, as the skilful herdsman would say, been going on until the result shows itself unmistakably in the condition of the plants or their produce? and instead of a moderate and easy change, a radical one seems indispensable, and the variety that six or more years ago was the greatest ornament to the parterre is consigned to the rubbish-heap, and something fresh is taken in its place.

This view of the matter is, perhaps, in nothing more clearly exemplified than in the case of the Dahlia, which, after being kept a number of years in one place, seems to degenerate in size, and in some instances the colour also is altered. This tendency, however, is more easily remedied with the Dahlia than with many other plants. A number of new varieties of the Dahlia are offered every season at a reasonable rate, and the number of plants required never approaches one-tenth of that of bedding plants in general, and the difficulty in meeting the demand is by no means great; but when ten thousand Scarlet Geraniums are wanted, and it is apparent that the variety hitherto depended upon to supply the want is no longer what it used to be, a change is forced upon the grower,

whether he be prepared for it or not, and, as stated above, the common practice has been to call in another plant, which in its turn will likewise be discarded.

Now, though this plan has certain advantages in bringing something fresh into notice, it would be well to inquire whether or no a real improvement takes place at each change. It is not fair to compare the new favourite with the old worn-out one; we should ask if the new is really better than the old was when it was a fresh introduction. The memory, it is true, will not always enable us to compare present appearances with those of long ago without the exercise of some of those feelings which are adverse to an impartial judgment. Certainly we are told that advances are being daily made, but it is well to ask ourselves if every change is an advance. The affirmative answer is one calling for caution when an old servant is about to be discharged. For instance, let us take a cursory view of some of the popular flowers of the day, and, calling to memory what they were, ask ourselves if they have progressed much during the last twenty years. Pinks and Carnations have been great favourites in their time, and were certainly better thirty years ago than now. The same may be said of the Auricula and the Polyanthus, and although the Heartsease is a more modern addition of the florists, it was certainly seen in better condition fifteen years ago than now. The case of the Dahlia is also somewhat similar, but more pains have been taken to multiply the varieties of this useful autumn flower than of the others, and though the kinds fashionable twenty years ago are but seldom met with now, they are well represented in their offspring. Other examples might be given, but it may be as well to turn to another phase of the subject.

Taking it for granted that new varieties of certain kinds of plants can be produced with facility to meet the wants of the public, let us see in what way the judicious retention of species having more constitutional vigour about them can be accomplished. Species of plants are unquestionably longer-lived and less likely to deteriorate than garden varieties, hence the advantage of using them when they are suitable; but it often happens that improvement in some form or other is wanted, and a variety is put forth possessing to a certain extent that improvement; by-and-by improved variety No. 2 supersedes No. 1, and the last is followed by others, and it is to be feared each of these changes is effected by a sacrifice of some of the constitutional vigour of the original species, and the consequence is that after a time the variety ceases to be so useful as before; disease and an impaired constitution give token that its term of years is fast drawing to a close, and that something else must be substituted for it.

Now, the retarding of this premature decay is what Mr. Fish says was in some degree accomplished in the case of the Calceolaria, by his having a batch of cuttings of the same kind from another place, which, no doubt, will succeed better for one or more years, but will in like manner want restoring, until the effort which Nature makes to restore her offspring can be no longer maintained, and recourse must either be had to the species, or to other varieties of later date. This being the case, would it not

be better for many of us to exchange plants or cuttings, or, where the extent of the place allows of it, to take cuttings from one description of soil to plant on another, so as to afford the change that seems so necessary to the well-being of the plants? Many large places afford such opportunities of exchanging plants, nevertheless in most it would seem to be better to import these from a distance, and from places differing considerably from that to which they are brought. I do not know whether the advantages said to result from seed wheat being imported from a cold, bleak, and unkindly place to one more favoured be real or not, but the poor place wants a change also, and this cannot be done on the same principle. Changes, however, may be beneficial, even when the natural conditions seem to be adverse rather than favourable, where the individuals occupying a particular soil show signs of being tired of it, and this is often done.

That change of soil and situation is attended with other results than the mere infusion of more robustness of growth is now and then apparent in the case of distinct species. The Hydrangea planted in one class of soil produces bright pink-coloured flowers, while in a peat soil of a certain class its flowers are blue; yet both plants appear healthy. So marked a difference, however, is not met with in other plants, nevertheless some change is often perceptible; but a distinct species will retain a certain amount of vigour under all circumstances, unless, indeed, it be placed where it ought not to be. Let us take, for example, some plants that possess all the distinctions of original species, and we seldom meet with disease amongst them; but changes of soil and situation are productive of other results, and, as in the case of the Hydrangea and some of our popular flowering plants, these present us with slightly different shades of colour when placed under different circumstances. Now and then examples of such variations are met with, and I will give an account of one that occurred some years ago, and in which it happened that both Mr. Fish and myself were interested.

When visiting Mr. Fish half-dozen or more years ago I thought a Verbena which he, like myself, grew rather extensively, differed from mine in colour. I brought a lot of cuttings home with me, and propagated them, keeping them apart from those which I had, but planting them close together at the proper time. The kind, I may observe, was one with which there is seldom a mistake, being the old palehella. Well, when flowering-time came there was a decided difference in the tints of the bloom when seen in quantity, that produced by the cuttings which I had from Mr. Fish having a more lilac tint, while that of my own plants was more of a lavender blue. This difference was tolerably apparent throughout the season, and there was so much diversity of opinion as to the relative merits of the two colours, that at the end of the season a quantity of each sort was propagated, one being named the light, and the other the dark. In the following season, however, the distinction between the two was all but imperceptible, and although care was taken in selecting cuttings from both again, no one could recognise any difference in the third year; and I may add that even in the first year the difference between the blooms of Mr. Fish's variety and my own was not so marked at this place as at that from which the cuttings came. Now, to what can we attribute the above difference but to the altered conditions in which the plant found itself? the habit being alike both at Putteridge-bury and here, and the character of the flower in every respect the same, except in colour, which it is easy to believe arose from the substances on which the plant fed.

This case, I believe, might be corroborated by others of a like kind, but I will only mention one more, and that is the blue Lobelia, which I have vainly endeavoured to obtain of the deep dark purple tint which it exhibits at so many other places. That soil and situation, or one of them, or some other condition prevents the attainment of this object I certainly believe; for although I have at various times procured plants or cuttings of kinds remarkable for the brightness of their colouring they seem to become paler when they are transported to our soil. Neither is seed exempt from the same result; in fact, I think seedlings have a greater tendency to become pale than cuttings, although both are used.

Referring again to the case of the Calceolaria, which presents fewer varieties than most of our popular bedding plants, rendering it, therefore, desirable to preserve good useful varieties true to their characters for as long a time as possible, I have no doubt that changing the ground in which they are grown will materially tend to promote this. It has long been the

custom of the farmer and cottager to have their seed corn and Potatoes from other ground, and to obtain fresh after growing either for a few seasons on their own land; and in the case of a plant which is reproduced by an extension of itself rather than by forming an independent existence, the change seems to be more necessary. There are before us examples enough of old kinds of plants falling into decay. Many people now complain of Tom Thumb Geranium not being equal to what it was, and this degeneracy would doubtless be in some measure prevented by the same process as that adopted with the Calceolaria. Other plants are equally likely to be influenced by change from one place to another. This is a subject deserving of more attention than it has hitherto received, and when fully understood many of those failures to which many plants are liable will be less frequent than they now are. Though the power to prevent them may not in all cases exist, it is something to be able to know the cause, and in the case of many of our common bedding plants much may be done to effect a change for the better.

I can with every confidence endorse Mr. Fish's views on the propriety of now and then having changes of plants, and if by so doing our gardens can be made more gay, and plants less liable to die off, some good will have been effected; and I have no doubt but such will be the result where the plan has that fair trial which it deserves.—J. ROUSSEY.

VIOLA CORNUTA AND ITS CULTURE.

This was introduced from Spain to the royal gardens at Kew, by Dr. Ortega, in 1776. A very correct figure of it appears in Curtis's "Botanical Magazine," vol. xvi., plate 791. It is strange that the plant should have remained unnoticed by any one, with the exception of its being figured and described in the "Botanical Magazine" above referred to, for nearly ninety years, more especially as it offers a shade of colour that has been so long wanted for toning down, and giving effect to the many strong and glowing colours which we possess amongst our bedding plants. The plant would, no doubt, have perished long ago but for its extreme hardiness. It thrives in any common soil without care, and when once the plant is established there is some difficulty in eradicating it, as the smallest piece of the root will grow if left in the soil, and will soon produce a plant.

It flowers very profusely in a dry soil, but thrives better, and produces larger and more highly-developed flowers, when grown in a rather moist and partially shaded situation. It seeds very freely, and may be propagated either from seeds or cuttings. The present is a good time to propagate it in either way.

The seed should be sown in shallow pans, and should be buried in the soil about 1½ or 2 inches deep; the pans should then be placed in a cold pit or frame.

Cuttings may be pricked out in pans; or some good sandy loam may be put into a pit or frame, if there is enough of cuttings at hand to fill a small box. If, as will most likely be the case, only a few cuttings are to be had at this early period of the plant's second advent, they had better be pricked out in pots or pans, and placed in a cold frame or pit as recommended above for the seed. As soon, however, as they are nicely rooted they should be pricked out into a small frame or cold pit in some rich sandy soil, where they will grow very rapidly, and by the end of March they will have made good, strong plants, when they may again be divided into a great number. They should then be planted out in nursery-beds, and by the first week in May the plants will be ready for planting out in their final quarters, where they will at once begin flowering very freely. The small plants in the seed-pans should have similar treatment to that recommended for the cuttings, but should not be pricked out before they have made the third or fourth pair of leaves.

Where early spring flower gardening is carried out, cuttings should be struck early in August and September, and the plants placed in their final quarters about the end of October. I intend, as I before stated, when I first mentioned the adaptability of *Viola cornuta* as a bedding plant, in my description of the bedding-out at Oulton Park, to try some experiments in crossing it with Mr. Tverman's varieties of *Viola montana*, as well as with many of the other *Violas* and Pansies. The late Mr. Beaton's double bedding Pansy will be one selected for a series of experiments with *Viola cornuta*; and if I can succeed in uniting the varied colours of the Pansy, and the delicious colour of the common *Violas*, with the habit and constitution of *V. cornuta*, combined with its profuse flowering all through the

summer months—if I can succeed in doing this, I shall be the means of introducing a class of plants to our gardens, that will not be easily surpassed for their beauty and usefulness.

I have not yet tried the plant in heat, but intend to do so, if I be spared this spring, and I have no doubt that it will strike as easily as a Lobelia, or a Verbena, after it has been growing freely in a gentle heat for a few weeks. If this should prove to be the case, those who do not possess the plant, by procuring a few plants now, may by bedding-out time raise some thousands from these. I have no doubt that *Viola cornuta* may still be found in the Chelsea Botanic Garden, from a plant in which the figure above referred to was taken.

Before the time for bedding-out shall have arrived, I will name some of the plants that may be used with good effect with *Viola cornuta*.—J. WILLS.

AURICULAS.

I HAVE often wondered how the doctor feels who, after having felt the pulses, looked at the tongues, and prescribed for the internal mechanism of half the county side, finds himself laid by, and cannot quite make out his own symptoms—nay, if a wise man, comes to the conclusion that he is about the worst judge of himself and his ailments, and sends off to his brother professional in the next parish to dose and doctor him. I have latterly thought, too, how the farmer feels when this dread rinderpest enters his stockyard, and sees one after another of his fine beasts hanging their heads and showing unmistakable symptoms of being attacked. I think I now know a little of it. This time last year I had as fine a collection of Auriculas as one need have seen. I had been consulted by Auricula growers far and wide, had prescribed for their maladies, had encouraged the forming of collections, and now I am reduced so in numbers that I am almost ashamed to own I have a collection. I have seen a disease which is quite as great a mystery as the rinderpest, and quite as destructive, making a clean sweep of dozen after dozen of my finest plants; and this, let it be remembered, of a plant which one cannot propagate as one will, nor, indeed, obtain for either love or money. I can quite sympathise with a good uncle of mine, on whose farm the rinderpest first appeared in these parts. "I didn't so much mind those I had bought; but when I saw those I had reared from their very calf-hood dying, it was trying work." Here were plants I had watched over from their tiny offset state, had been growing up to be blooming plants, and they are now dwindled away. How this has come about I know not, but as it commenced after their being repotted I must presume it was something in the compost. Yet I had prepared this with the greatest care: it was all old, the manure thoroughly well rotted, and the loam apparently good. I had repotted every one myself, had been attentive to the watering, kept them from rain, and did, in fact, all I had told others so often to do, and yet they went. They did not damp off, but fairly dwindled away. They seemed resolutely to refuse to root in the pots, and, of course, there was no hope for them. Had I thought of this sooner, even though it was their season of rest, I should have moved them out of it; but it was only in correspondence with Mr. Lightbody that it was suggested to me. He told me, and Mr. C. himself confirmed it to me, that Mr. Campbell a few years ago lost nearly all his collection by using loam in which iron existed. In my case I am afraid something of this kind was the cause. Unfortunately there is no grower within fifty miles of me, and hence we cannot take counsel together about them, as I could about other flowers, if they were going wrong. If *Gladioluses* are queer, or *Geraniums* spotty, one can easily find neighbours who can talk with you about them; but the Auricula has so few friends that we are not often thrown together, and hence we must consult our own judgment, which is often at fault.

I have been led into these remarks by a request forwarded to me from "A. C." who wants to know about fertilising Auriculas—first, how he is to cross them, &c.; secondly, whether he is also to fertilise with their own pollen those which produce seed shyly; thirdly, whether any one would exchange duplicates with him. With regard to the first question, I do not believe that cross-breeding has been much attempted with Auriculas, and I am confident no certain results could be relied on by any such process. The same pod of seed will produce green, grey, white, and self varieties, and even the Alpine type; and I should say that if cross-fertilisation is to be attempted, I should advise that the constitution of the mother plant be

considered, and the colour or form of the male parent. Thus, for example, I should take Waterhouse's Conqueror, and fertilise it with the pollen of Chapman's Marie, or Lovely Anne, and put on it the pollen of Violet, and in some such way endeavour to obtain the various properties which are considered essential to the making of a good flower. All Alpine flowers should be excluded from the frames of any one who is particular in growing for seed: and, of course, it will be necessary to prevent the intrusion of bees, moths, &c.

As to the second point, there is little doubt, I should think, that fertilising with their own pollen would ensure greater certainty; but I have never found that there was any great difficulty in obtaining seed, although I have never been able to afford the time and trouble necessary for raising seedlings.

As to the third point—the exchange of plants, that is a difficult matter also. Probably his better plan would be to make out a list of the plants he has, affix his price to them, and endeavour to obtain a customer for them, and then lay out the purchase money on varieties which he does not possess. If he wishes to do that, and will send you such a list, I shall gladly try to help him in the matter. I repeat that my own plants are in such an unhealthy condition that I could not offer any of them in exchange; and, indeed, exchanges rarely answer—each party considers himself hardly done by, however anxious each may be to act fairly. Indeed, as he is a near neighbour of Mr. Turner, of Slough, he would find little difficulty, I should think, in making some arrangement with him.

I have come to the conclusion that for us, at any rate, in these southern latitudes, the best time for repotting is immediately after the blooming season is over rather than in the autumn. The plants have by that time been growing away for some months, and I do not think they so readily make roots then as they do when in the height of their growth—at least this is the plan I purpose pursuing this year. It is Mr. Turner's plan, and there is no better grower than he is. If I fail this year I shall close the concern, and go in for growing Cabbages or Potatoes. The only way in which I can console myself is, that I could not tell that the loam was bad. *Geraniums* thrive in it lustily; but then they grow in almost anything, while the Auricula is as dainty in its food as a countess's lap dog. I am not one of those to say die, and so I shall not give up yet, and wish "A. C." and all other lovers of the flower better success than has attended—D., Deal.

THE ESPERIONE GRAPE—WINE—POTATOES.

WITH regard to the Esperione Vine, and in reply to "A VINE AMATEUR, *Stowmarket*," I beg to say that in consequence of numerous letters addressed to me on the subject, I wrote to Mr. Rivers, of Sawbridgeworth, offering him a bundle of cuttings from the Vine which I formerly received from Mr. Oldaker; and at the same time I requested Mr. Rivers to allow me to mention the circumstance in these pages, as I had no doubt that it would be welcome by a great many. Mr. Rivers kindly answered me as follows:—"I thank you for your offer of a bunch of Esperione cuttings. I have been the great champion of this sort, which I have cultivated for twenty-five years. Some few years ago Beaton disputed with me in the Journal about it, and wished the world to think it was merely a variety of the Hamburgia; but I would not give in for his Esperione leaves died off yellow, while the true sort, as you well know, has its leaves in autumn of a fine crim-on and purple. Once or twice, nine years ago, I bought some Vines under the name to supply orders, but they all proved wrong, their leaves at once betraying them."

I was born between Stowmarket and Bury St. Edmunds, therefore I can guarantee Stowmarket to be just the neighbourhood to suit the Esperione, and not that "A VINE AMATEUR" can succeed in procuring the true kind, I trust he may eventually have the same success with it in my dear native county as I have had in Oxfordshire. In 1855, from the Vines growing against the stone wall in the open air, I have taken 374 lbs. of well-ripened Grapes, clear from their stalks, from which I have made forty-six gallons of wine, and it promises to be very good. I am also almost ashamed to own that I cut a hundred bunches of the Grape for eating from one Vine growing under glass, and the same Vine produced ninety-seven fine bunches of Grapes in 1864.

"D." of Deal, is wrong in supposing that it was I who recommended to him the varieties of Potatoes he mentions at page 62. I have grown Sutton's Racehorse, and it proved so

much like Mitchell's Early Albion Kidney, that I do not grow it now, and I think Mitchell's the better. Myatt's Ashleaf I grew when it first came out. It is a first-rate cropper; but I gave it up as being with me deficient in flavour. With some tubers of Rivers's Royal Ashleaf I was kindly presented by the raiser, and I grew it for the first time this season. The Lapstone Kidney deserves all the praise that is bestowed upon it; but Paintree's New Kidney (for which, by-the-by, we received two first-class certificates at the International Exhibition of the Royal Horticultural Society at South Kensington, last December, one certificate for it in its most natural condition, and the other for it as a Kidney), is of the same strain, and it is earlier, and a better Potato still. I strongly advise "D." of Deal to give this first-rate sort a trial in his enlarged practice. I never cared to give the King of Potatoes a trial; why, I cannot tell. As regards round Potatoes partaking of an earthy flavour, I have a seedling which, if I have the pleasure of presenting some another year to your excellent correspondent, will, I hope, serve to convince him that there are round Potatoes to be grown as good as Kidneys.—UPWARDS AND ONWARDS.

PEAS FROM MAY TO OCTOBER

There are but few who do not take an interest in Peas, the very mention of which at this time of year is enough to make one's mouth water; and as it has been a hobby of mine to obtain a good succession of them, and having kept a table of results, I will lay before your readers my experience on this subject.

In the first place, I may mention that I grow all my crops of Peas on the natural or out-door system, having neither time nor convenience for sowing under glass, hardening off, &c. As early in January as the ground is in good working condition, I select a piece of a south aspect border that has been previously manured and ridged, and levelling it down with a fork, sow Carter's First Crop in rather shallow drills, putting slips of furze along the rows before covering up, to keep off the mice. I always used to grow Sangster's No. 1 for my first crop; but Carter's First Crop is, in my opinion, far superior to it. Early in February I sow in an open quarter of the garden two rows of Sangster's No. 1, each about 30 yards in length, drawing the drills a little deeper and putting in chopped furze as before; but after this I am not so particular in the sowing and protecting; if only the ground is dug deeply, well manured, and the slugs kept trapped, there is not much danger of the crop not doing well. For the succeeding sowings I generally use two quart's of each variety at a time. Before the end of February I follow with two rows of Dickson's Favourite, and about the middle of March sow a like quantity of Yorkshire Hero—a first-class Pea for flavour; and Veitch's Perfection, two rows in the beginning of April. In the end of the same month I sow Bedman's Imperial; early in May, two rows of British Queen; and lastly, Knight's Dwarf Green Marrow in the end of May or beginning of June. Now, judging from the selection met with in the majority of seed catalogues, mine to some persons may seem a strange one; but my experience of it at any rate satisfies myself, and keeps the cook in tolerably good humour, considering that I have twenty or more persons to supply.

According to my memoranda the following is the order in which the several crops come in for use—viz., Carter's First Crop, May 26th; Sangster's No. 1, June 14th; Dickson's Favourite, July 5th; Yorkshire Hero, July 17th; Veitch's Perfection, July 20th; Bedman's Imperial, July 27th; British Queen, August 20th; Knight's Dwarf Green Marrow, September 14th, and being till the beginning of October.

The chief points in the culture of Peas are to keep the ground about them well hoed, to earth them up a good height before sticking, which should be done as soon as required; if dry weather is apprehended, to mulch with good long manure, and to water them if necessary. I may add, that should any of your readers think fit to try my selection, I have no doubt that with ordinary success the result will be Peas from May till October.—W. C.

PUTTYING ORCHARD-HOUSES.—As there is some difference of opinion on this subject, I directed my glazier to putty my orchard house only in parts. During the short frost in January seven panes cracked. Every one was unputtied. Whether the cracking arose from the freezing of water between the laps, or from the want of that resistance to the weight of snow which a

puttied frame presents, I will not undertake to determine; but the result is in favour of putty, and I give my experience to your readers.—G. S.

CUTTINGS OF HYBRID PERPETUAL ROSES.

As a Rose amateur in a small way, I have noted your correspondent "CORCYRA CRANE" in your Journal of December 26th, and without attempting to answer the questions generally contained in his letter, yet the remark as to cuttings from Hybrid Perpetual Roses would seem to imply a difficulty, which, from experience, I can say does not exist if only the most ordinary care is observed.

My plan is to take the cuttings from about the last week in July to the middle of August—Paul's "Rose Garden" gives the exact description of what a cutting should be. Well, I simply insert from four to six, according to the size of the pot which may be handy, in a nice light mould, composed of one-third of sandy peat, or any sweet light sandy stuff, the remaining two-thirds sifted loam and a little burnt earth, just to make the whole light, and calculated to encourage the quick formation of the rootlets. This season I filled as many small pots as I could manage with cuttings from such as Charles Lefebvre, Souvenir de la Malmaison, Princess of Wales, Jules Margottin, Devoniensis, John Hopper, Madame Boutin, &c. These pots were plunged in the Rose-bed, well watered, and a hand-glass placed over every ten pots or so; then a sheet of stout paper is covered over the whole of the glass and kept there for ten days or a fortnight, or otherwise the sun would make short work of the matter. Then the covering is partly removed—say from about half the surface of the hand-glass, and in five weeks or so I find the cuttings are for the most part struck, with here and there a few which are easily removed and not missed, because from the first more cuttings are placed in the pot than are expected to strike root.

About the middle of September I carefully turn out the cuttings, and place each in a separate pot. Now, this is really an operation requiring care; the cutting will be noticed with long white rootlets, so brittle that if the soil be pressed lightly they will snap asunder; therefore, I merely hold the top of the cutting in one hand in the pot, and just drop the compost with the other gently, give the pot a few shakes so that the roots meet the soil, and then place it, plunged to the rim, in the Rose-bed wherever convenient. The sun at this period of the year will hardly be too powerful to injure them if the syringe is freely used. At the end of October I house the whole safely in a cold frame, such as is used for Cucumbers; but raised on a bank 2 feet from the surface. Mine is but a small one, and at this time holds about four or five dozen pots, each with a young plant from a cutting as already explained.

The very little trouble required in striking cuttings from many of our most famous Hybrid Perpetual Roses, to my mind, renders the consideration of the question as to first budding on the Manetti of little consequence. If we wish for Roses on their own roots, it is quite certain that we can always have them so, except some few that will not strike, as Madame Vidot. With this Rose I never could succeed; but as the same difficulty is experienced at the nurseries where every appliance exists as to bottom heat, &c., this failure need not discourage an amateur.

The following are sure to strike—viz., Charles Lefebvre, Jules Margottin, Souvenir de la Malmaison, Devoniensis, Lord Palmerston, Triomphe de Rennes, Gloire de Dijon, Général Jacqueminot, and Duc de Rohan. Perhaps the Tea Roses may not in cool seasons be so much depended upon as the Hybrid Perpetuals.

My idea from the first has been in favour of Roses on their own roots; in short, there is in many places soil quite unfitted for the Dog Rose, and the failures must be many. However, as a matter of taste, let every amateur try for himself, and act accordingly.—HENRY TAYLOR, *Lower Edmonton.*

POMMIER DE PARADIS.

A FRIEND of mine has just handed me a list of fruits by a Mr. Scott, of Crewkerne, and directed my attention to the following paragraph, "Procure your Apples grafted on the 'Pomme Paradis.'" I was so astonished at seeing such advice that I could scarcely believe any nurseryman could give such directions, my own experience is so opposed to the use of this stock. Many years since I was so struck with the pretty little Apple trees grown near Paris as single cordons, that I

ordered some thousands of this stock (Pommier de Paradis), on which I was told the French nurserymen worked their trees for the purpose. These stocks were received in spring, and made a capital growth the first season. The following winter was a severe one, and more than half the stocks were killed. As I was interested in the matter, I left the others unworked, to see how they would go on, and they were badly infested with aphids, and some died during the heat of summer. After the next winter so few remained alive that I destroyed them, and never planted another stock of the kind.

As nothing is more important than stocks to the cultivator of fruits, I should like to know how far Mr. Scott's advice is found to coincide with the experience of others. In the same work persons planting Pears on the Quince are told to plant above the graft; here they would root from the scion, and soon grow on their own roots. What do you say, Messrs. Editors?—J. R. PEARSON, *Chilwell, Notts.*

[We think you are right.—Eds.]

KEMPSEY AND BLACK ALCANTE GRAPES.

In the Number for January 30th, under the heading "Notes on Grapes," I am surprised to find you state that the Kempsey Alicante is the same Grape as Morocco. In Dr. Hogg's "Fruit Manual," edition 1860, page 107, Kempsey Alicante is described in such terms as led me to procure a Vine of the sort, which, from the foliage, appears to be correct; of the fruit I cannot speak. At page 109 is described a very different Grape, Morocco, much inferior to the other. I am desirous of having the Grape, be its name what it may, described in the above work as Kempsey Alicante. Will you please inform me if I possess it? or must I apply to Mr. Meredith for it?

Perhaps it would be an assistance to some other of your readers if Dr. Hogg would explain if the Kempsey Alicante sold by nurserymen corresponds with the Grape of the same name at page 107 of his work, or with Morocco at page 109, and also state what is the Grape Mr. Meredith advertises as the real—BLACK ALCANTE.

[The Kempsey Alicante Grape described in the "Fruit Manual" has been discovered to be identical with BLACK MOROCCO, but very different and very inferior to the Black Alicante sent out by Mr. Meredith, and which is frequently called now "Meredith's Alicante." This latter we believe to be the true Alicante of Speechly, which has for some years fallen out of notice and cultivation, except in a few gardens where old Vines are still in existence. It is one of the finest late black Grapes.]

THE ROYAL HORTICULTURAL SOCIETY.

At the anniversary meeting to be held this day at 3 P.M., the Council propose that the three retiring members of their body shall be J. J. Blaudy, Esq., John Kelk, Esq., and Major R. Trevor Clarke; and that those replacing them be Viscount Sandon, the Right Hon. W. Cowper, M.P., and Sigismund Rucker, Esq. As office-bearers for the ensuing year, it is proposed that the Treasurer and Secretary be G. F. Wilson, Esq., and Lieut.-Col. Scott, R.E., to replace J. Kelk, Esq., and W. Wilson Saunders, Esq.

The new regulations as to the admission of young men as students into the Society's garden at Chiswick have likewise been determined on. The principal requirements are that the candidate shall be at least twenty years old, be recommended by a Fellow of the Society, and have served three years in good gardens, and in one such garden not less than a year. Further, he must be able to write and spell well, and be tolerably proficient in arithmetic. Good character, it is scarcely necessary to add, is indispensable. The wages of the young men admitted under the above conditions are to be 12s. per week, but rewards for meritorious work will be added.

THE meeting of February 10th was an improvement on the former exhibitions of this class in the present year, and was much more numerously attended. It is evident that there is a growing desire among amateurs and nurserymen of decorative plants to take advantage of the opportunities these meetings afford of exhibiting their productions to a class of visitors who, perhaps more than any others, can appreciate them; and now that London is "filling," and these Saturday promenades are attended by the *élite* of the fashionable world, we hope to see a greater variety of these choice little collections than hitherto.

Mr. Cutbush again sent a collection of forced flowers, similar in

every respect to that we described last week, the centre of the group being occupied with the graceful Solomon's Seal. On this occasion Mr. Cutbush rather overdid it by introducing six plants, instead of the four which harmonised so well in his last exhibition. It seemed as if the harmony of the group was destroyed by too much of one thing. Still the plants were very graceful, and were beautifully grown. For this an extra second prize was awarded.

The speciality of the meeting was prizes for six ornamental plants; and the first prize was awarded to Mr. Young, gardener to Mrs. Barclay, of Highgate, with a handsome plant of *Yucca aloifolia*, *Azalea indica* Nosegay, *Draucana Cooperi*, *Rhododendron Cunninghamii*, *Epilendrum cochleatum*, and Duke of Wellington Hyacinth. Mr. Bartlett, of Shaftesbury Terrace, Hammersmith, obtained the second prize with *Rhodora canadensis*, a hybrid *Epiphyllum*, and pots of the *Hyacinthus Grand Lilas*, *Circe*, *Tubiflora*, and Charles Dickens.

Mr. Cutbush also exhibited a fine collection of eighteen forced bulbs, which received an extra first prize, and consisted of four pots of Hyacinths, four of Tulips, and ten of Crocuses, and also twelve plants of the lovely little *Prunus sinensis flora pleno* forced in pots. They are like libanatian double-blossomed Cherries. They received a first-class certificate.

Messrs. F. & A. Smith, of Dulwich, sent a collection of eight very beautiful varieties of *Primula sinensis*, many of them double, the finest of which were incarnata, a fine flesh-coloured variety, and Queen of England, white with a blush centre. *Kermesina splendens plena* is a fine rosy red and very double. Some of the single varieties were also very good, such as *fimbriata superba*, of immense size, and fringed round the margin of the corolla; Carnation, prettily striped, &c. These received a first-class certificate.

Mr. Young received a certificate for a collection of Gourds, and Mr. Bartlett an extra third prize for a collection of forced Hyacinths.

Messrs. Lucking Brothers again exhibited a choice lot of forced flowers, for which they received a certificate.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CHAMERANTHEMUM BEYRICHII, var. *VARIEGATA* (Variegated-leaved Beyrich's *Chameranthemum*).—*Nat. ord.*, Acanthaceæ. *Limn.*, *Didymia Angiosperma*. Native of Brazil. Leaves edged with dark green, centre very pale.—(*Bot. Mag.*, t. 5557.)

LUISIA PSYCHE (Butterfly-flowered *Luisia*).—*Nat. ord.*, Orchidaceæ. *Limn.*, *Gynandria Monandria*. Native of Borneo; imported by Messrs. Hugh Low & Co. Sepals and petals pale yellowish green; lip tessellated with violet-purple spots.—(*Ibid t.* 5558.)

THIBAUMIA CORDIFOLIA (Heart-leaved *Thibaudia*).—*Nat. ord.*, Vaccinæ. *Limn.*, *Decaduria Monogynia*. Native of the Andes in various provinces of New Granada. Flowers scarlet, tipped with yellowish white.—(*Ibid t.* 5559.)

BAUHINIA TOMENTOSA, var. *GLABRA* (Glabrous variety of Downy *Bauhinia*).—*Nat. ord.*, Leguminosæ. *Limn.*, *Diadelphia Decandria*. Native of Benguela, Ceylon, Malabar in India, and of Natal and other places in Africa. Flowers primrose colour, with deep purplish crimson blotch at the base of the upper petal.—(*Ibid t.* 5560.)

EULOPHIA EUGLOSSA (Pretty-lipped *Eulophia*).—*Nat. ord.*, Orchidaceæ. *Limn.*, *Gynandria Monandria*. Native of the banks of the Old Calabar River in Africa. Sepals and petals green; lip white, streaked with purple.—(*Ibid t.* 5561.)

TILLANDSIA XIPHOIDES (Buenos Ayres Air-plant).—*Nat. ord.*, Bromeliaceæ. *Limn.*, *Hexandria Monogynia*. Grows on trees in Buenos Ayres and at Mendoza, as well as other places at the foot of the Cordillera. Flowers white and deliciously fragrant.—(*Ibid t.* 5562.)

ACUCUA JAPONICA VARIEGATA.—A berried specimen.—(*Floral Mag.*, pl. 277.)

VERBENA—*Really Blue*.—A variety possessed by Mr. Bull, Chelsea; "a really blue variety."—(*Ibid pl.* 278.)

CHRYSANTHEMUMS.—*Iona*, bright golden. *John Salter*, bright orange.—(*Ibid pl.* 279.)

CALANTHE VEITCHII.—A pink-flowered hybrid Orchid, raised by Mr. Dominy.—(*Ibid pl.* 280.)

PEACH—*Early Albert*.—Raised by Mr. Rivers, of Sawbridge-worth, who in this branch of fruit-culture has been most successful.—The *Early Albert Peach* is of rather large size, roundish, and frequently higher on one side of the suture than the other, and with a dimpled apex. Skin greenish yellow, and covered with small red points on the shaded side, but deep crimson, becoming sometimes almost black, when grown against a wall and fully exposed. Flesh white, very tender, and melting, with a faint brick red tinge next the stone, from which it separates freely, and with an abundant, sugary, and

vinous juice, which is very rich. It is a first-rate early Peach ripening in the beginning of August."—(*Bl. list and Pomologist*, v., 17.)

THE HANUM, OR TAFAN FRUIT.

In riding over the hills between Jericho and Bethel we found some fruit on a plant which was entirely new to us, and, as in many respects it appeared to be of a description pleasing to the eye, delicious to the palate, and with an agreeable aroma, I determined, if possible, to bring home a few seeds, that it might have a chance of being introduced as an addition to our dessert fruits. From the time of the year at which I found the fruit well ripe on the plants, I fancy that it will not be difficult to cultivate; for, as the plants appeared to have reached maturity when I found them, on the 28th April—that is to say, before the really hot summer weather of that country had commenced, it appears that the cooler period of the Syrian spring is sufficiently warm; and the best proof that it will stand a moderately low temperature is, that on reference to my journal I find that the temperature in our tent at night was 55°, and at sunrise 12° on the day when I found a plant of the "Hanum" in full bearing.

The plant resembles the Melon in habit, growth, and leaf on a smaller scale, and appeared to carry from six to ten ripe fruit at a time. The fruit is about the size of an Apricot, of a bright yellow colour, with a thin skin, which separates easily from the ripe pulp, in which I found from twelve to twenty pits or seeds; upon being crushed or opened the fruit yields a most delicious aroma, which of itself would make it a valuable addition to our dining tables.

The soil in which the plant grows is the red stony loam like that of our Westmoreland hills, and I was told that the plant only grows on the hill tops in the neighbourhood of Bethel; but I also met with it on the high land between Samaria and Jenin. Not knowing it botanically I call it by the native names, and my object in writing this description of it is to inform you that I have a few seeds to spare, and shall be happy to place them in the hands of such of your friends as are most likely to succeed in cultivating the fruit to perfection. I sent a liberal supply of the seeds to the Royal Horticultural Society, which I have no doubt their able gardener will test this spring, and, I hope, be able to increase the stock.

As regards the cultivation, I venture to suggest a course similar to that adopted with the Melon with plenty of ventilation, for the plants appeared to grow on open exposed spots of the hill tops. The soil should not be too rich; if possible, as nearly similar to the native red stony loam as can be; and as the plants appeared to be of rapid growth and maturity, I do not think that the seeds will require very early sowing.—*W. WAXLEY.*

EXTENSIVE SALE OF FRUIT TREES.—We beg to draw the attention of our readers to a notice which appears in our advertising columns of a very important sale of fruit trees, to commence at Adams's Nursery, Acton Lane, Turnham Green, on Wednesday the 21st inst. The stock comprises upwards of 50,000 Apples, Pears, Plums, and other fruit trees; also a number of ornamental trees and shrubs, all in fine condition.

ROUGH TREATMENT OF FIG TREES.

After reading the remarks made by your correspondent G. Dawson on the pruning of Fig trees, I believe there is great truth in his statements, for I well remember that six or seven years ago I called to see an old gardener with whom I was acquainted—he was one of those old half-century-gardeners—and after walking round to see his plants, some of which, especially the Conifers, were very good, I went to the kitchen garden, and in one corner there stood a large Fig tree. It was a standard, with a stem somewhere about 2 feet in circumference, or 3 feet in diameter rather more. I asked him if he obtained any Figs from that tree. He replied in the affirmative; and I then asked him if he ever pruned it?—and how he managed it? Then at once he said, "Lord bless 'ee, I get up with a hatchet or a hand cut and cut off a joint limb sometimes, and I get as many Figs as you could eat." It was the Black Ischia, as well as I can recollect.—*W. HARRIS, C. S. in London.*

There are many worthy old gardeners who delight in saying strange things to astonish the "green ones." "The hatchet and the saw" are rather extreme weapons for using much among Fig trees. Yet it is no less true, as stated the other

week, that where the climate is good Figs will do better if the bearing branches are allowed to hang a little from the wall, instead of being closely tacked to it. In the south of the Island, as in places in Devonshire, they do admirably as bush standards in the open air. Mr. Tillyard, at Bentley Priory, gives a good deal of liberty to his Fig trees out of doors as well as under glass, and with good results, which, with other things, we hoped to have noticed long ago. The Fig does not like a too high temperature; and with shoots pretty open, close to a wall, the heat in spring and summer is often too great, injuring the young fruit, and scorching one side of the ripening fruit. We knew of two Fig trees, close to a stable, with a good aspect, and in a warm sheltered situation, that bore abundantly every year, and the worthy proprietor would allow no one to touch them but himself, and all the pruning they had consisted in his taking out a few shoots now and then when they became too thick, and putting a string round others to secure them a little to the wall, so that the winds should not break them down. We shall also say that, when nailed to the wall in the usual way, the finest Figs we ever saw out of doors were against a wall with an east aspect, on which the power of the sun would cease after 10 A.M. The finest Fig trees out of doors, without any protection, which we ever saw were a row of dwarf standards at Manhead. The large luscious fruit were a sight. We have no recollection of anything of the sort north of London.

Your correspondent Mr. Dawson (page 90), states what I have often heard before—namely, that Figs bear better when not trained closely to the wall. If such be the fact, I can only account for it by supposing that shoots close to a wall are excited earlier in spring, and the young fruit, from want of protection during frosty nights, is cut off; while shoots far from the wall hardly show for fruit until the season of danger is nearly past. I do not uncover my walls till the 1st of April and cover again on cold nights.—*G. S.*

POTATO VAGARIES.

For a rather considerable number of years I have made Potato culture a small hobby on which I have taken a gentle annual trot, trying to test the qualities of the many sorts which have been the subjects of very "tall talk," *alias* puffing. From all that has passed under my notice relative to this most valuable article of food, I am not surprised to find poor Mr. Paterson tried in the north and grumbled at in the south. "A benefactor to his species, and his Potatoes a boon to mankind," at Dundee—after dinner; while one of our most experienced gardeners in Surrey can find but little good or exemption from disease in any of his new sorts. This is the result of one trial in one season, and is doubtless true. I am not defending or wishing to write up Mr. Paterson's Potatoes, but only to point out the changes that take place in even our old sorts of Potatoes in different seasons and in different soils. All experiments are of value, even that of "D. Deal," who planted his half a peck of each sort in his small garden, and then told us what he had done and how he cooked and ate them.

I have hitherto considered the Kidney Potatoes as the only kind fit for the tables of those who appreciate a good Potato; and among them for many years, in my opinion, the Ashleafs have taken the first rank for flavour, which is so peculiar and so good. I have found but little or no difference in the varieties known as Myatt's Royal, &c.; but I think I have been able to distinguish that the closer the adherence to the parent of all the race—the old Ashleaf, in the varieties brought out or raised from its seed, so much nearer to perfection are they in flavour. Next to the Ashleafs in flavour is the Lapstone or Haigh's Kidney. It must be some fifteen or more years ago that I saw, spread out in a shed in the nursery of Messrs. Backhouse at York, a large quantity of a most beautiful-looking Kidney Potato. They were being greened for seed, and were called Haigh's Kidney. It was some time before I learnt their *alias*—Lapstone. As a matter of course I ordered a one, and gladly commenced their culture. The first season, to my great discomfort, they were prostrated by disease, so that I had difficulty in saving enough for seed—very small tubers. The second season they suffered more from disease than any other kind, and continued to do so for three or four seasons. In spite of this their flavour was so good that I could not think of discontinuing their culture, and so I persevered; still I considered

the sort delicate in constitution, and only fit to grow as a luxury. For the last seven or eight years a marvellous change has come over this sort. Its habit is more robust, and it has resisted disease so as always to retain its flavour.

I now come to the year 1865 and its Potato vagaries. In the month of February I planted on a rough hotbed, made of manure, leaves, and refuse, my usual crop of Ashleafs of two or three kinds—the Old, Myatt's, and the Royal. The bed was 6 feet wide and 80 feet long. On the 20th of May I commenced digging new Potatoes, and my supply lasted till the end of June, the quality of all excellent. Ashleafs in the open borders were then commenced and found to be equally good, the Royal producing largely. This state of things lasted till the beginning of August, when heavy rain commenced, and with it the disease, which in a day or two reduced the vines to mere dry stalks, but leaving the tubers to appearance entirely free from disease. To our surprise we found our favourite Ashleafs from a piece of light soil had lost their flavour. We tried them from loam, from clay, from peaty soil near the river—they were all alike flavourless, or at least they had only the peculiar insipid taste of the Fluke Kidney. We endured this with patience, for on trying the Racehorse, the Imperial Kidney, the Prince of Wales, *alias* "Boon to Mankind" (which said "Boon" was very rotten, and the few saved very uneatable), Mona's Pride, almost uneatable (how can any grower compare this to the Ashleafs? It is not earlier than the old sort, and never has any flavour), the Lemon Kidney, and the Silver-skin Kidney, some of which were sound-looking, all were found flavourless and uneatable. What a ridiculous illustration of the folly of giving prizes for uncooked Potatoes! Verily it is something like "testimonials" to new early Peas, many of which are not only alike, but very old sorts with very new names. These matters are not creditable to the age; they lower the status of tradesmen, and make people hold up the finger of scorn.

Driven from our Ashleafs, which we have generally depended upon till late in October, we turned to our winter favourite the Lapstone about the middle of September. On digging them up the crop was found good, the tubers remarkably sound and handsome, and we thought we were safe for the winter. After our cook's usual mode—the only way to cook Potatoes—the Lapstones were steamed in one of Barlow's steamers, and brought to table. To our surprise they looked glum and sullen—not a jacket unbuttoned as usual, and to our still greater surprise we found them close and almost flavourless. We endured this during the whole of October and nearly all through November, when, as a *denier ressort*, I ordered them to be peeled, boiled, salted, and dry-clothed. This has brought on a change for the better; but their delicious flavour is gone—they are flukish, and only fit for London dining-rooms.

Not quite satisfied with the state of our Potato affairs, I thought of my spring favourite—I must explain that my three sorts have hitherto been Ashleafs and a few Ten-weeks for spring and summer, Lapstones for late autumn and winter, and the King for March and April; so anticipating and hoping to find "all right," I ordered a dish of Kings to be steamed in "Billy Barlow," as some jesters stigmatise the immortal steamer, on Tuesday last, January 30. They came, but they did not conquer, for their jackets were closely buttoned; others looked like a dyspeptic an hour after being tempted into taking a glass of fine old port—isn't the feeling horrible? Well, our Kings turned out much worse than our Lapstones. They were close, ill-flavoured, and indeed uneatable; so much so that, depending upon a great treat—delight in a good Potato—no other sort was cooked, and I was compelled to dine on half a King, and not a savoury one, as he of the Cannibal Isles might have been. As a forlorn hope I have to-day (Feb. 2), had some Pink Fluke, or Queen of Flukes, steamed in their jackets. Like the three sorts above named, they are close and ill-flavoured. I quite hoped to find the King and Queen of their usual good quality.

It is curious to note these abnormal features in Potatoes of the growth of 1865. I am not aware, and have not heard, of their quality in other places from good observers. The round sorts are, I believe, as usual dry and floury, but they are not usually placed on the tables of those who do things well.

Potatoes were green and flourishing here (Herts), till August the 14th, 1865, when, after heavy rains, on or about that time, the vines died off suddenly, emitting before doing so that peculiarly offensive smell indicative of the disease. The tubers of some kinds, however, were full grown, and did not suffer in appearance. The crop of Lapstones and Royal Ash-

leafs was particularly abundant and sound, but their fine flavour was gone. The sorts of Kidney Potatoes that suffered most here have been Mona's Pride, nearly all rotten; the "Boon," *alias* Prince of Wales, the Imperial Kidney, the Silver-skin, and the Lemon; most of these were masses of rotteness. The King and the Pink, or Queen of Flukes, resisted the disease to a great extent, for their tops were green a month after the others were brown and dried up, but their tubers are, as I have above stated, not of their usual quality. I was struck last spring with one kind of early Kidney Potato which I had thought so delicate and shy in bearing as not to be worthy of cultivation. From some peculiarity in the weather this sort came up well, grew well, and bore a good crop, proving the earliest of all except the Ten-week. It is known as Hudson's Early May.

I have thought it worth while to give this history of Kidney Potato culture here in 1865, because it will, I think, show that in some seasons and in some soils Potatoes vary in quality to an extent almost beyond credibility. As to the reason why fine full-grown tubers should lose their flavour because their tops died off a week or two before their usual period, and after the roots were full-grown and nearly ripe, it is a question for the physiologist.—FORWARDS.

SEEDLING GRAPES SPORTIVE.

In an interesting article by Mr. T. M. Lindsay at page 502 of the last Volume, he remarks that he is somewhat sceptical about the crossing of Grapes, and says, "I believe that the majority of Grapes sent out of late years as cross-bred varieties are in reality no crosses at all, but simply sports from seed." I will grant that this opinion is true in some cases, for the Editors, in commenting on Mr. Lindsay's illustrations, remark that these "furnish another proof that in the vegetable as in the animal kingdom, when a fixed form has once been broken in upon, there is no end to the vagaries that follow." I have been fertilising Grapes, and rearing seedlings from these, for the last twelve years, but I never thought of taking the trouble to sow seeds, unless fertilisation had been carefully practised with a view to effecting improvement in the quality, productiveness, habit, &c.; nevertheless, I consider the experiments made by Mr. Lindsay in sowing the seeds of the Black Hamburgh Grape, without crossing, very interesting and instructive, particularly to those who have been in the habit of growing Grapes from seed.

I do not now intend to give an account of my successes and failures, I wish only to mention the peculiarity of light Grapes being produced from seed taken from a black parent, and that, according to what has been stated by eminent growers, even without cross-fertilisation. I am convinced, however, that the colour is sportive, for I have this year obtained a true white variety in every respect from that new and superior black Grape the Muscat Hamburgh; and what is still more confirmatory of this view is, that in the present instance the female parent, or Muscat Hamburgh, was most carefully crossed with my own new Champion Black Hamburgh, no doubt there was white blood in the male parent, it having an infusion of the Canon Hall (white) in it.

I believe that it will be fresh in the memory of all the readers of this Journal that Mr. W. Thomson, of Dalkeith Park, raised a white Hamburgh Grape from the Black. The same is now, I think, named the Champion Golden Hamburgh. Mr. Lindsay's experience also fully proves that the common Hamburgh, at all events, is very apt to produce white seedlings. It remains to be proved if other varieties will do the same.

Assuming the foregoing to be correct, particularly as regards Grapes with which cross-fertilisation has not been resorted to, are we to obtain new Grapes improved in their properties, more particularly in respect to flavour and size, without recourse to artificial fertilisation? From what experience I have had, I would decidedly answer, No. I do not deny that solitary instances may occur of an improved Grape being produced by chance; but from what I have proved, even with careful crossing, success is not always attained.—WILLIAM MELVILLE, *Dalmeny Park Gardens.*

MILDNESS OF THE SEASON.—The mild month of January has had such an unusual effect upon vegetation here, at Hawkhurst in Kent, that an account of the plants in bloom out of doors may not be uninteresting to your readers. On the 7th of January a Lord Suffield Apple tree presented us

with a truss of bloom; on the 9th Snowdrops and Crocuses were in full bloom; and on the 19th the first Daffodil made its appearance. All this, perhaps, may be unusual, but not so surprising as when I state that on the same day some Rhododendrons of the ponticum varieties expanded some trusses of bloom; and on the 21st we had a bright scarlet one a mass of bloom, about thirty trusses being all expanded at once. *Souvenir de la Malmaison* Rose also gave us some good blooms. Many hardy shrubs are making growth. Peach trees are on the march, and the vegetation of many other plants is becoming more or less active. I should like to know if this is the case elsewhere. If so, it will be necessary for every gardener to have a watchful eye to the weather, and have plenty of protecting material at hand; otherwise we are likely to lose the bloom of many valuable plants, and have our prospects of fruit destroyed.—T. Bacon.

On New Year's-day of the present year I picked from my garden—a terrace one, and exposed to easterly winds—six ripe Strawberries of a very fair average size, and nearly equal in flavour to a summer Strawberry.—F. K., *Wilmington, Salop.*

GLOXINIA CULTURE.

I have often wondered that Gloxinias, a class of plants possessing so many beauties, are not more generally cultivated. They may be had in bloom throughout the summer and autumn, and if we take into account how simple their culture is, I think there are few plants that better repay the attention bestowed upon them. Where a succession of bloom is required the tubers must be started into growth at different times, allowing from four to five weeks between each lot; and as the time to start the first is at hand, I have thought the following remarks on their culture might be of use to some of the numerous readers of *THE JOURNAL OF HORTICULTURE*.

Early in February take from their winter quarters the pots containing the dormant tubers, and place them on a level surface, then with the watering-can give as much water as will moisten the soil, which will have become dry during the time the tubers have been at rest. This done, plunge the pots in a bottom heat of from 65° to 70°, but if bottom heat is not at command, ainery that is at work will answer very well. With due attention to watering, the tubers will in two or three weeks have started, and begun to grow freely. Then, but not sooner, turn them out of the pots and carefully shake the old soil from them, doing as little injury to the fibres as possible. Transfer them to clean, well-drained pots a size larger than those from which they were taken, using the following compost, which I have found to suit them admirably:—Two parts decayed leaves, one part fibry loam, and one part dried cowdung broken into little lumps about the size of cob nuts, adding as much silver sand and fine wood charcoal as will give the whole a nice friable texture. This compost should at the time of its being used be nice and dry, and of the same temperature as the structure in which the plants have been growing.

The soil being in readiness, proceed with the repotting by first draining the pots, an operation which must be done efficiently, as the well-doing of the plants depends in a great measure on this. On the top of the drainage place the roughest portion of the compost, pressing it firmly down with the hand, and fill the pots until by placing the tuber on the soil the crown reaches to within an inch of the top of the pot. Then fill in between the pot and the tuber with the finer portion of the compost, give the pot a few smart taps on the bench, which will cause the soil to penetrate amongst the fibres, and finish by pressing the soil round the tuber with the fingers, leaving the crown just peeping through the soil. This being done, give a gentle watering with tepid water, and return the Gloxinias to their old quarters; if in the bark-bed place a small flower-pot, not inverted, beneath each, which will prevent worms from entering, and allow the water to pass off freely.

After the pots have been blazed for a fortnight raise them one-half their depth, and in another fortnight lift them entirely out of the bed, placing the plants where they can have as much light as possible, but not near a fire or hot-water pipes, as dry hot air is very injurious to the foliage. Examine the plants daily, and see that no suffocant fumes from water. That used should always be of the same temperature as the house in which the plants are growing. Be also careful not to over-water, as if the soil becomes saturated they will cease to thrive.

As soon as the plants begin to show flower remove them to

the warmest part of the greenhouse, as the flowers should expand in the same heat as that in which they are to remain. In hot weather a slight shade will be necessary during the hottest part of the day. As the plants go out of flower water must be gradually withheld, and they should be placed in a position where they can have all the sun possible; this will cause the tubers to ripen and go to rest, which is necessary to their future well-doing. During the period of rest these must never be exposed to a temperature below 45°.—J. HARRISON.

GROWING MEALY POTATOES.

"Dr. Deal" is quite a Corypheus among flowers, but I cannot say as much for his knowledge of Potatoes. He should have known that meeliness or waxiness in Potatoes is much under our control. If he had taken the native habitat of the Potato, the chemical constituents of the soil there, and compared it with the analysis of a healthy and a diseased Potato, he would have found suggestions enough. The Potato is an alkali plant. Our manured soils have a correct relation to the Wheat plant, a phlo-phatic plant, but little to the Potato. A waxy Potato is full of developed albuminous cells; but the cells are not all filled with starch. Phosphatic manures favour the production of albuminous compounds, and alkalis the production of starch. Now, if "Dr." of Deal will add alkalis liberally to his rich garden soil, he can grow even sound Potatoes as mealy as he likes. Sulphate of magnesia is one of the best Potato stimulants we have, and it is cheap, 7s. or 8s. per cwt. Sulphate of soda, dry—i.e., not crystallised, technically the salt cake of the alkali manufacturer, is another—say 5s. per cwt. Nitrate of potash is the finest stimulant of all; but the price is beyond the reach of ordinary Potato growers; but these like "Dr." of Deal, who are very partial to good Potatoes, and to whom cost is a small consideration, should use it freely—say per acre, to soil full of phosphates:—2 cwt. nitrate of potash; 2 cwt. sulphate of soda; 2 cwt. sulphate of magnesia; 2 cwt. common salt. A poor soil in all constituents would also require 4 or 6 cwt. of guano, or superphosphate. If the nitrate of potash is left out, except in manse gardens, the remainder will be found a valuable and a profit-paying manure.—W. Ross, *Herefordshire.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

ATTEND to the drainage of your gardens, for at this season, when frequent forkings and turning over of previously trenched ground are requisite, it is easy to perceive the advantage and great importance of efficient drainage. This, of course, refers to soils that do require drainage, because some do not. How beautifully the earth mellows and crumbles down, and how much sooner it comes into a fit state for cropping, when the drainage has been properly attended to; nay, more, the labour it requires is much less, because all pulverising operations are more easily performed. If the soil be undrained the labour is far greater to bring it into anything like condition for the reception of crops, and even then the progress and produce of the crops committed to it are greatly inferior to what they are in the former case. We would, therefore, endeavour to impress upon the minds of all who cultivate the soil with the view of receiving an adequate return for the labour bestowed upon it, that a thoroughly efficient system of drainage is the basis of all successful cultivation. Persevere in hoeing, surface-stirring, and dusting with lime amongst all advancing crops, and do not forget to put good-sized readable labels to every crop, with the name in full, and the date when sown or planted. This will save much trouble hereafter, and the results, if transferred to a journal, will be valuable for future reference. *Cucumbers*, make another sowing of Early Horn. *Cucumbers*, the greatest attention should be paid to the bed for the first fortnight after the plants have been turned out, the first-ripened should be examined daily, as it is a much better criterion to rely than a thermometer, which only indicates the heat of the atmosphere in the frame. Cover up according to the heat of the bed; if this will allow of it, a small portion of air should be left on every night; this may be done in the evening, after the frame has been closed three or four hours. *Endive*, continue to blanch the late crops. *Lettuce*, attend to

the ground, use should be warm, and the air moist. In an airy greenhouse the leaves become shabby. Eds.

surface-stirring, and to the removal of decayed matter from the autumn-planted on sloping banks. *Onions*, plant the bulbs of last year which begin to grow, they will be found very useful where there is a scarcity of sound ones, they may also be planted for seed. Plant the Underground sort, if not done in the autumn. Weed and clean the autumn-sown. *Peas*, if the soil is in good working condition put in now the first principal crops of Tall Marrows, British Queen and Victoria, in the open quarters, sowing Spinach between the rows; as this ground comes in well for Celery, the Peas should have the full width of 6 feet from row to row, the Spinach will come off in time for the trenches to be made for the Celery. Continue, also, to sow successions of Early Peas, Longpod, and Windsor Beans, according to the demand. *Parsley*, a sowing should be made as soon as the ground is in a fit state to receive the seed. *Potatoes*, plant some Ash-leaved Kidneys on a warm sheltered border if the weather is mild and favourable. *Radishes*, sow a succession. Continue the operations of manuring, trenching, and forking over the ridges whenever the weather will permit.

FRUIT GARDEN.

Pruning and nailing Peaches, Nectarines, and Apricots, may be followed up with vigour and perseverance, whenever the weather is favourable. Wall fruit trees of any kind that are becoming crowded with wood near the top of the wall should have some of the larger branches headed back, and the shoots trained below. Do not crowd the centre of fan-trained trees with too much wood, that part will always fill up enough.

FLOWER GARDEN.

Take every opportunity to forward the ground operations in this department. Now is a good time for the formation of beds for Bourbon, China, and Tea-scented Roses. Take the soil out to the depth of 12 inches, fill up with rotten dung from old hotbeds, or any other source, tread it firmly as the bed is filled, place 3 inches of soil on the dung, and plant in the usual manner. During open weather give standards some good waterings with drainings from the dung-heap. Prepare beds for Carnations and Links, strong turfy loam, with rotten cow or sheep-dung added, forms an excellent compost; let the beds be 6 inches above the surface of the ground. Have the Pansy-beds in readiness, choose a strong rich soil in a shady situation, if the blooms are wanted in perfection. Top-dress Auriculas and Polyanthus with a light loam, made rich by adding rotten cow-dung. This is a good time to take off the offsets before top-dressing, plant them three or four in a five-inch pot, and place them in a shady part of the frame. Sow seed in shallow pans, and place them in a cold frame. Place roots of choice Dahlias in a little heat to start for cuttings. Plant out biennials in masses, where requisite. Lose no time in finishing the planting of trees and shrubs.

GREENHOUSE AND CONSERVATORY.

The conservatory now should be full of interest, and ought, where much attention is paid to flowers, to be as full of beauty as at any period of the whole year. Any Camellias done blooming should, if possible, be removed forthwith to some of the houses at work; a moist atmosphere, a temperature averaging 65°, and a canvass shading overhead are the requisites in order to cause them to produce wood freely and large leaves; the shading must by no means be neglected. The early-forced bulbs will now be out of bloom, and should be removed to some sheltered place from which frost is excluded in order to ripen their foliage, and other plants introduced from the forcing-pit. Hibiscus, Clerodendrons, Justicias, and other half-stove plants which flower in the conservatory may be pruned, and some of them placed in a higher temperature, but they should not be potted until they begin to grow freely. A few Neriums and Hydrangeas may be also forced into early growth for this house. A gentle heat would now benefit the Chinese Azaleas for early flowering. Continue to give as much air daily to the greenhouse as the state of the weather will admit of, and see that all plants are watered regularly; the great object is to keep these plants from growing early. Proceed with the potting of such Heaths as require shifting, using the upland peat for the hardwooded kinds, and the rich lowland peat for the softwooded ones.

STOVE.

Do not at present excite *Ixora*, or such plants as *Franciscea macrophylla*, which have set their blooms, but young plants of all kinds, to make the most of them, must be started immediately. *Rondeletias* to be cut-in, and started in the warmest part of the house. Pot a few plants of *Gesnera*, *Gloxinia*, and *Achimenes* for early blooming. Prepare tan and other ferment-

ing material for renewing the bottom heat towards the middle of March. Increase the moisture and temperature gradually as the days lengthen. See that suitable composts are ready under cover for potting and sowing seeds.

FORCING-PIT.

Continue to introduce fresh supplies of plants as the former ones are removed to the conservatory, also other plants from which you wish to obtain an early crop of cuttings. Common plants that do not promise much bloom should be at once discarded to make room for others, failures of this nature always occur more or less in early forcing.

PITS AND FRAMES.

Here, if the number of plants required for bedding-out is considerable, there will be plenty of employment for all hands. The whole of the autumn-propagated plants must be potted off without delay, so as to have them well rooted and turned out into sand in temporary pits by the 1st of April, in order to set the pots at liberty for a second lot of plants, which should now be coming forward in the propagating-frame. Make all possible speed in potting on the young stock of *Fuchsia* cuttings as soon as struck, placing them in a kindly bottom heat. A number of *Amaryllis* bulbs should now be shaken out, and repotted in half-decayed turfy loam mixed with a small portion of sand and a pretty liberal supply of charcoal.—W. KLANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

JANUARY, and February, too, as far as the latter month has gone, have been regular "fill-ditches." The ground has not been so soaked in this neighbourhood for years. A plentiful provision has now been made for a dry summer; not only from the water collected in pools and ponds, but from that which has sunk down to raise the height of the springs, which in many cases had fallen unusually low. The soaking of the undersoil will also furnish a supply of moisture to meet a rapid evaporation from the surface. It is pleasant to think of these things when we cannot do as we would like in the kitchen garden. Almost everything rightly viewed has a bright side, if we will only look for it; and much of human happiness consists in the ability and habit of looking at the bright side and not on the dark. In the one case, too, the mind is strung to energy to conquer difficulties; in the other, every little obstruction becomes a huge lion in the way. What complaints have already reached us that Peas and Beans and many other crops cannot be put into the ground. Well, what is the use of the repining? We have sown the same sort of Pea in November and in the month of March, and sometimes we have gathered the last-sown first, and generally within a few days of the other. We would not now, to secure earliness, sow or plant either crop until the ground were nice and mellow, at least not for some weeks to come. To be sure of an early crop, however, we would sow in boxes, on turf, in semicircular drain tiles, &c., and keep in a snug place, and transplant when all was right as respects the ground. Transplanted Peas and Beans will ever be earlier, other things being equal, than those that are sown. In most gardens where any potting is done, there will always be some dry stuff beneath the potting-bench, which will be useful for covering seeds in wet, heavy lands; but in all such soil it is better to refrain from sowing when the ground is claggy and wet, and watch for the first opportunity when it is friable and rather dry.

Except to collect the necessary vegetables we have scarcely done anything in the kitchen garden for a fortnight. If our stutish ground were either dug or trenched when in a soaked state, it would hang together like indian-rubber or bird-lime all the summer. If we planted when the ground was in such a state, every mark made by the feet of the men would require much breaking and forking to make it friable and kindly in summer. Light sandy soils of course can be worked almost at any time. Good heavy soils should never be puddled when wet. When worked comparatively dry they are nice and mellow all the season. We have seen such soils dug, trenched, and ploughed when exceedingly wet, when the truest economy would have been to have kept spade and plough locked up. The fine bursts of sunshine between the storms of rain and the hurricanes of wind, are the cheerful omens that better weather is coming. There need be no lack of work, though little can be done in the open ground. The garden must be small indeed, if a few weeks of profitable labour cannot be spent without even putting a spade in the ground.

Proceeded with all in-door cropping, as Kidney Beans, Seakale, Mushrooms, Rhubarb, Asparagus, &c., as detailed in previous weeks; and went on with planting for cover out of doors, where holes were made in turfy or hilly ground, and the damp was rather an advantage than otherwise, the ground being rendered softer and more friable in consequence. Where ground lies on a slope, a grassy turfy covering is almost as good for preventing anything like soaking as it is for keeping out any great amount of frost. Trapped, and though rather averse to such a course, put poison in places where nothing else could reach, it for mice and rats, which are becoming very troublesome. They have completely stunged in and destroyed most of our earliest Cauliflowers. Our reserve of Cauliflowers for the table is now over; but Broccoli I am in. These garden cucumbers will throw us back for early Cauliflowers. The plants were stunged in one night, and the most provoking circumstance is that the whole seemed done for mischief more than anything else, as leaves and stems were left lying in heaps, and little or nothing had been consumed. We have a wire trap or two for rats, with the spring so strong that if caught at all death must be next to instantaneous. It is a terrible thought of even a rat being tortured for hours, caught by the leg in a common steel trap. Even a trap should have something of the humane about it. We may have the right to kill what we call our vermin enemies, we can have no right to torture.

FRUIT DEPARTMENT.

Owing to the weather and the wetness of the ground we have done little in the way of priming or nailing out of doors. Had we been scarce of in-door or other more suitable work we could have gone on by using planks, &c., to stand upon, thus taking the weight from the soil. Some times we took advantage of the snow covering to give our orchard-houses a good smoking with bruised laurel leaves, so as to penetrate into every hole and corner of the house, merely by way of precaution; and in the same way of precaution we washed all the glass and woodwork thoroughly with weak soap water, so as not to spoil the paint, and syringed and engineed the same, as well as the trees and walls, with clear water. As we see little chance of washing the trees, which we generally do, we did the next best thing—syringed them thoroughly, also the wall at back, with weak soap water at a temperature of about 140°. If there should be any eggs of insects, that temperature should pretty well kill them. As soon as primed we will paint the trees all over with a thin paint made of lime, soot, sulphur, and clay, with about a pound of Gishurst to the six gallons. This, when dried, being of a lightish colour, will help to keep the trees back in opening their buds, and the more backward they are in opening the blossom, the less likelihood is there of the trees being injured by a severe frost; and mild though the weather is now, we have known the thermometer to range from 40 to 50 in January and February, and yet stand but from 20° to 25° below freezing-point, in the middle of March, and even a dry and quiet atmosphere would hardly save blossoms then, though they will stand a great amount of cold when the atmosphere is still and dry. We do not, therefore, envy some of our friends, who tell us that the buds in their unheated orchard-houses are now opening, and some are proud to think that they will gather fruit all the sooner—we hope they will; and if there should be no frost to speak about, this will certainly be the case. As, however, we are anything but beyond the usual time of frost, we would advise all, and especially beginners, who have fruit trees in these unheated houses, to keep them back as much as possible by air and day for a few weeks, and even a little shade, if the sun should be very powerful, will be useful for retarding.

Like all trees and a glass, the roots of ours were becoming rather dry from no water being given late in autumn or through the winter. If the soil become very dry, any of the buds will be apt to drop off before the blossom can and. Some friends are much alarmed at a few of the buds dropping off before the blossom appears; but if this takes place moderately it just saves thinning the fruit afterwards. The dryness at the roots, however, continues too long with trees that have well-ripened wood, not only will the buds be apt to drop too freely, but this will take place if you at once water liberally. In the one case the buds will drop from want of moisture; in the other they will be thin and off by too much water given at once. It is advisable, therefore, in the case of trees planted out, to water only about a third of the root surface, waiting a week or so between the time of watering, and of the other two-thirds. The only advantage of the comparative dryness in autumn and the first part of winter is that it secures

greater ripeness and induration of wood, and consequently more perfect flowers. One noticeable fact of such well-ripened wood is that, under similar circumstances, it will expand the blossoms later than trees of which the wood was not equally well indurated. Chiefly by shutting up with sun heat we had one little orchard-house considerably earlier than another with more air left on; but the house that was latest last season has the buds much more forward this spring, and though the wood in both is studded with buds and looking well, the wood in the first house that had more sun heat, but up in it is, if anything, the larger and the firmer. On the same principle hard, well-indurated shoots of Vines break more slowly than shoots not so well indurated when placed in similar circumstances. Hence in the case of Peach trees out of doors, after a dull autumn, there will be little danger of the fruit-buds dropping in spring—they will even be more easily excited and expanded than after a bright sunny autumn; but most likely after a dull autumn, having consequently less indurated wood, many of the fruit buds will be apt to be defective, either in their female or male organization, and very likely in both. One drawback to washing Peach trees, &c., with brushes, and even painting them with a smother-up paint, as safeguards against insects is, do the work as carefully as you may, some of the buds will be unsettled, and will fall off when freely swelling; but where there is an abundance of buds the loss of a few is of no consequence, and washing and painting to keep vermin and insects away is much more economical and better every way than smoking and washing to destroy them when they come. Prevention in this case is better than cure. It is well known that in some of our great mercantile establishments, insects, though kept pretty well under, cannot be eradicated; so much so, that purchasers, especially of tender plants, should for some time keep them in a sort of hospital if their collections are all clean and right.

In sunny intervals drew the hand dry through the trusses of Strawberry blooms, and waved a board like a fan over Peach trees in bloom; and where the flowers were at all thin brushed them gently with a camel-hair brush, or the soft side of a feather. In consonance with what is said above, we may mention that in the case of Noblesse Peaches and other kinds that bloom very freely, it is often of great advantage to select the best blossoms—those that have fine prominent pistils and well-made hawthorn, and to thin the others out pretty liberally. We once had a Noblesse Peach tree under our charge that was said to have bloomed very freely for a number of years, and yet set its fruit very sparingly. By sharply taking off fully three-fourths of the blossoms there was always plenty of fruit as long as we knew or heard of the tree. This made less thinning of the fruit afterwards necessary. Potted off Melon plants, sowed more seed.

In other departments went on much as in previous weeks, allowing everything to come on slowly until we have a change of weather. For Peach-house and similar structures little fire heat is necessary, as, though stormy and windy, the temperature is high. We have had to pin the most of our sashes, doors, and ventilators to keep them secure.

LIME AND SULPHUR MIXTURE.

This, alluded to by "J. M., *Lancashire*," page 103, is none the less useful, though it can lay no claim to novelty, as a number of years ago, and several times since, we gave the recipe and the mode of its application in this Journal. We borrowed the chief part of it from a Frenchman, whose name we forget, who used it as a preventive of the mildew on the Vine, and also for effecting the cure of that evil. "J. M." gives the exact quantity of the materials, and what strength to use it, quite correctly. We may just add, as confirming his statements, that it should not be used for Melons at above half the strength specified, and never used at all if the leaves afterwards are not quite dry before the sun touches them. For nothing else in a greasy state should it be used stronger than he specifies—that is, half a pint to the four gallons of water. In no case should it be given to Strawberry plants swelling their fruit. The boiling of the sulphur and the quicklime makes the mixture very strong and acrid, a pound of sulphur will thus go a great way. When the liquid cools before bottling we generally boil a second time, and this second brewing is not so strong as the first. It is a useful wash, but for general purposes it will be safer to diminish the quantity rather than increase it, and especially for everything growing and tender. Our chief reason for alluding to it now, however, is for stating that if Peach trees and Apricots in late unheated houses are not washed and painted with clay and sulphur composition, &c., then such a

wash over the walls and trees, before the blossom-buds swell much, will be no bad compromise, and in that case the wash may be used stronger. We may also add that even in the reduced state it should not be used for Peaches after they take the second swelling; in fact, for red spider such a wash applied carefully to the heating medium will be more effectual than syringing the trees, and with the composition applied to the pipes clear water may be used for the trees night and morning. A hot dry atmosphere is what the red spider delights in, and the cooler and moister the air, the less will the insect relish it. When the red spider visits us it generally commences over a hot corner, and thence spreads. Even then sulphur fumes given off at about 150° and plenty of moisture are about the best cures; but the wash alluded to by our correspondent is also useful for keeping the spider away, and sending it adrift. It is used most safely either where there is no fruit or when the fruit is small and young. We feel sure that "J.M." will excuse these remarks. In the case of mildew, &c., the mixture, useful at all times, will be most safely applied when the trees are in a comparatively matured or dormant state. The milky liquid, as described by "J. M.," leaves little or no traces behind it, but it does leave a strong scent about the hands and the wrists of the operator if he do not syringe carefully. We once used it three times over a short row of Peas, and it cleared them of the mildew.

ORNAMENTAL DEPARTMENT.

We have done little in the pleasure grounds. We tried digging a little, placing a board on the grass verges; but it was too wet for our liking. When not too wet, a good chance was given for moving, transplanting, and planting trees and shrubs. We have already stated how we planted a good deal for cover and future usefulness. We made holes and planted pretty well as we went on, turning the turfy covering into the bottom of the holes. We did so to avoid two evils:—First, the soil turned up beneath the grassy covering was stiffish, but more dry and friable than we expected, and it packed nicely among the fibres, which it would not have done if we had waited until the fresh-turned-up soil became wet; and again, if sudden frost came the soil would be too hard for planting. Last year we saw some planting done in frost and snow. A great many holes had been made, and in the change of weather there was nothing to do but plant, but it would have been better to have paid the men for doing nothing. What a sight the trees presented afterwards when the thaw came! If planting is done early in autumn the holes may be dug some time, and the soil be exposed to be aired. When holes are made in winter, and the planting is performed in spring, then favourable weather may be chosen to use the earth about the roots in its best condition; but when planting must be done in winter it is in every way safest to plant pretty well as the holes are made, and then if unfavourable weather come holes can be made when nothing else could be done. Of all times for planting and transplanting we consider the end of October and the beginning of November the best. The ground is still warm then, and roots are encouraged during the winter to meet the wants of the swelling buds in spring.

Finished a good deal of *potting* among Ferns, Mosses, Geraniums, Pelargoniums, &c., and must try and collect a lot of tree leaves, or we shall be at a loss for bottom heat and other heat. A little extra heat will soon be as acceptable as the want of artificial heat was valuable in summer and autumn. We shall leave these matters just now, however, to allude to some simple matters necessary to success in the case of all beginners in a small way, like our enthusiastic correspondent, "H. S."

First, then, see that the plants are clean in stem and leaf, as alluded to the other week. Do not follow the example of your neighbour, and put your plants out of doors in the rain to be washed. We will say nothing of a cold soaking at the roots; but how would you like to be set out in a rain at even 29° from a room at 65°, and be kept pining there for hours?

Secondly, Be sure that the pots you use are clean-washed. Warm water is best, and the pots will dry sooner, and never use them before they are dried. In cold weather the plants will not dislike the pots being heated a little, say to 60°, before using them.

Thirdly, Let the soil you have collected from the sides of the highway be nicely aired, dried, and heated. If on taking it firmly in your hand and squeezing it, it takes the impression of your fingers, but on laying it down gently on a table it crumbles to pieces, it is just in right condition. If on laying it down it retains its position, marks of fingers, and all together,

it is too wet. You may easily heat and dry a small quantity by placing a portion in a bag near the fireplace or over the oven, and then mixing it well before using it. The soil should range in temperature from 55° to 65°. A cold soil often gives a check that it requires weeks of careful tending to surmount.

Lastly, At present in shifting your plants keep them in the cold as short a time as possible. If you cannot do the work in the house carry the plants back as soon as you can. Thousands of plants become insect-covered and of bad constitution, because clever people will fill a shed with fresh-potted plants, and then they will begin and carry them, after being starved, into a warmer place.—R. F.

TRADE CATALOGUES RECEIVED.

Downie, Laird & Laing, Stanstead Park, Forest Hill, S.E. and 17, Frederick Street, Edinburgh.—*Catalogue of Garden, Flower, and Agricultural Seeds, &c.*

Sutton & Sons, Reading.—*Sutton's Farm Seed List—Supplementary List of New and Choice Flower and Kitchen Garden Seeds.*

E. P. Dixon & Son, Yorkshire Seed Establishment, 57, Queen Street, Hull.—*Catalogue of Seeds for the Farm and Garden.*

COVENT GARDEN MARKET.—FEBRUARY 10.

Trade has improved, and prices have advanced. The demand for forced fruit and vegetables, in particular, is greater. Of English Pines the supply is still short; but Grapes are amply sufficient for the demand. Lady Downie's is to be had very good, and a few Muscats may still be obtained. Dessert Apples and Pears are no more than equal to the demand; the former chiefly consist of Nonpareils, Blenheim Pippin, and Sturmer Pippin; the latter of Beurre de Rance, very good, Ne Plus Meuris, and Easter Beurre. For forced vegetables the demand is improving. Salads from the Continent are now coming in very good; French Cos Lettuce brings from 6s. to 7s. per dozen, Cabbage Lettuce from 15s. to 18s. Some Ash-leaved Kidney Potatoes have made their appearance, and may be had at 2s. 6d. or 3s. per lb. Out-door produce of all kinds in season continues to be abundantly supplied. The Potato market is still heavy.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

OUR JOURNAL (W. T. J.).—If you remit 17s. 6d., with your directions, you can have the Journal, stamped, from our office for twelve months.

COTTAGER'S GARDEN SOCIETY (W. T. J.).—As you can have only one show annually, we recommend you to have it in July.

ORCHID BUDS (W. G.).—As you wish to retard the blossoming, the best thing you can do is to give all the air possible, night and day, and to shade from sun. Our croquet-house trees are scarcely moving at all.

CINCERIA SEEDLING (L. P. L.). It is one of the best we have seen. Petals stout, velvety, free from notch; colour rich crimson-purple with slight white at the base, so arranged as to form a star. What the habit of the plant is we cannot say.

FLOWER BORDERS (C. H. E.).—The plan would look very nice if Golden-leaved Geraniums and Bignon or Alma (white-leaved), were used alternately, and if on gravel, a ring of blue Lobelia went round all. (E. S.).—The lines of the proposed borders will look very well, but they would be better if 24 instead of 20 inches in width. 1 and 2, will do very well, and so will 3, 3, but if these are to be light-leaved Geranium and Variegated Alyssum, then, certainly, we would not make the circles between 2 and 3, marked 7 and 8, white Verbenas, or if we did, we would give them an edging of lilac or purple. 5 and 6 will do well as Purple King Verbenas, and more especially if you make 4 not Christine and Lady Plymouth, but Christine and a soft yellow.

HEATING A SMALL GREENHOUSE (L. P. L.).—The smallest boiler and three four-inch pipes will do amply for what you want in a greenhouse 18 feet by 9. Five Vines on one side, and two on the other will also be enough, and we should be inclined to plant all inside. The border 2 feet would do, but if you can go under the window lattice, so much the better. The sorts for hardness we would recommend are—two Esperince, two Royal Muscadine, and three Black Hamburgs.

INSECTS (A. B. C.).—What you call insects, are the larvae of small black and orange-coloured flies of the genus *Dilophus*, which appear in May and June in great numbers in gardens. We believe that in the larva state they feed upon decaying vegetable matter in the earth.—W.

WARNING A GREENHOUSE (L. P. L.).—We have no doubt that any of the modes you refer to, or a small stove, with pipes from it, heated by gas, would suit your purpose in such a small house; but we should consider it only waste of labour in vain to seek any other mode of dispelling draught and keeping out cold, when there is already a fireplace and flue leading into the dwelling-house chimney, the great fault of which are too strong a draught, consequently too much heat, and the quick burning out of the fuel. If there could be little draught obtained there might be reason for giving up the flue; but the flue being there, and the draught so strong, all you have to do is to lessen the draught. To do this, have a close iron door, also a close-fitting ash-pit-door, with one hole in it, which you can regulate by a pin or otherwise, giving a quarter of an inch of an opening or more after the fire is set to work. If even this do not give you a gentle draught enough, then put a damper in your flue before it enters the chimney. If even then the fire burn too bright or fast, place plenty of damp ashes on it. There is no difficulty in making the draught as weak as you like.

EVERGREENS FOR NORTH WALL (L. M.).—*Catalpa pitaecantha* though not so fine nor so quick in growth as Ivy, will, nevertheless, grow and cover a large space on a north aspect; so, too, will *Cotoneaster microphylla*, and *Berberis Darvillii*. As, however, the wall is partially shaded by trees, we should plant Ivy. In the border by the wall you may plant common Laurel, Hollies, Yews, and Aucubas. Nothing does so well in shade as the different varieties of Periwinkle, and they would succeed well as a bordering to the others.

PLANTING OVAL BED (Hem.).—We presume you propose planting your large oval bed by the carriage-drive with low shrubs. Nothing would be better than *Ardisia*, or *Rhododendrons* of the Catawbiense varieties, which are moderate in price, and edge the bed with *Erica carnea*.

LILIA REPTANS CULTURE (Nemo).—Your plant, like many that have been subjected to cool treatment, has not had sufficient heat during the growing season, hence after nine months it has not completed its growth, and this is what some orchids subjected to cool treatment do, for having been previously kept in a great heat, there is not sufficient heat to stimulate growth in the season, in which they are subjected to cool treatment. The consequence is, they take a second rest instead of growing, or should they not do so, growth is so slow, and prolonged to solate a period, that it is not completed by the time they should, under other circumstances, be recommencing growth. Your plant will complete its growth under its present conditions as regards heat, by spring; you may then keep it throughout the summer without water, but sprinkling it overhead occasionally, and in an equal temperature as possible; at the same time a dry atmosphere should be maintained, for if the air become moist growth may be made at an advanced period of the year. You will by these means secure a thorough ripening of the plant, and in the following season it will succeed well in ainery, and in a temperature of from 40 to 50 in winter. It will be desirable, therefore, to rest the plant next summer if you can, and it will in the succeeding year make its growth at the proper time and ripen them off for flowering. In summer, or when vegetation is active, it should have a temperature of from 65 to 85, and afterwards 75 from fire heat will be sufficient. Whilst growing it requires an abundant supply of moisture, especially in the atmosphere, but at other times it should be kept cool and dry. Of the year six months should be occupied in growth, and six devoted to rest, and the plant then is the reverse of a shy bloomer; but it is necessary that it make a good growth, and that this be well ripened, otherwise the flowers will be few and far between.

CHRYSANTHEMUM THOMAS CULTURE (Hem.).—You are doing right in keeping the soil rather dry at this season, but it should not be so dry as to all the leaves, and these are no worse of being a little yellow now. Your temperature in summer is too low. It should be 65 at night, and 85 by day. The plant may be fresh potted at the end of this month or early in the next; but if it grow vigorously and you do not wish for a large specimen, do not pot, but make the drainage good, remove a little of the old surface soil, and replace it with fresh. In pruning, thin out the shoots, shortening some and leaving others at their full length. Encourage growth with a moist atmosphere, and afford the plant a light and airy situation. After growth is made reduce the moisture, give more air, and diminish the supply of water at the root, and thus the thorough ripening of the wood will be secured. On this depends the flowering. Do not train the shoots very closely together, but allow space for the admission of air and light. It is a beautiful free-flowering climber.

BOX NUMBER OF COTTAGE GARDENER.—If you enclose four postage stamps with your address, and state that you want the Number published June 27th, 1865, it will be forwarded to you by post.

TOP-DRESSING CROQUET GROUNDS (P. C. M.).—Your croquet ground, the grass of which is much scorched in summer, should now have a dressing of well-reduced manure. Two tons will be a good dressing for a full-sized croquet lawn containing an area of 794 square yards. Spread the dressing evenly over the surface, and after a fortnight's dry weather take advantage of the first shower and draw the back of a wooden rake over the ground, and in the first week in April pass the daisy rake over it in order to clear off any pieces of sticks and straws. All stones should likewise be cleared off. Roll well, and after the first mowing your lawn will show no signs of the manure, and the grass will grow much faster and will not be so liable to burning in summer.

CUTTING DOWN APPLE TREES FOR GRaftING (Hem.).—We do not see what mode of grafting your gardener proposes to adopt, after cutting off the heads 1 foot above where they are to be grafted, unless it be side-grafting, which is different from that stated at page 290, No. 246, and certainly not eligible for old Apple trees. In that case it is not necessary to pare the outer surface of the cut at all, for the grafts will be 1 foot below that. The directions given in reply to "AMATEUR," at the page above referred to are the only ones necessary, and by no other means can the modes of grafting there mentioned be successfully performed. Your gardener may have a plan of his own.

KITCHEN AND DESERT APPLES.—LATE PEARS (Hem.).—*Kitchen Apples*:—Ariston, November to April; Dumelow's Seedling, November to March; Hambleton Bonny Ann, January to May. *Desert Apples*:—Cockle Pippin, January to April; Adams's Pearmain, December to February; and Lamb Abhey Pearmain, January to April. *Pears*:—Beurré de Rance, February to May; and No Plus Meuris, January to April. We grow these and know them to be good.

SHRUBS FOR BORDER (L. S.).—Your border not being suitable for *Rhododendrons* and American plants generally, you might plant *Berberis Darvillii* and *B. aquifolium*, and these would do for the rows next the walk, as they are evergreen and do exceeding well on light soil over gravel. *Berberis aquifolium* should be next the walk. At the back you could have a line of *Ribes*, another of *Persian Lilacs*, and a third of *Philadelphus coronarius*, planting them, the first two 4 feet apart every way, and the remaining three 6 feet apart. The *Berberis* and the *Ribes* will flower in April, the *Persian Lilacs* in May, and the *Philadelphus* in June.

SOWING GRASS SEEDS (A. B. C.).—We think that as the present sward is very coarse, it would be better to sow Grass seeds, and for that the ground should be in as good till and as clean as if Carrots were to be sown. In the first dry weather in April, with the early prospect of rain, sow the following:—*Lolium perenne*, tone, 6 lbs.; *Cynosurus cristatus*, 24 lbs.; *Festuca duriuscula*, 14 lbs.; *Festuca tenuifolia*, 1 lb.; *Poa nemoralis*, 1 lb.; *Poa superevrens*, 1 lb.; *Trifolium repens*, 2 lbs.; *Lotus corniculatus* minor, 1 lb.; and *Trifolium minus*, 1 lb. Slightly rake the ground after sowing, and roll immediately. It will be green by the middle of May. Let the Grass grow until July, then cut it, and every three weeks afterwards until the third week in September. Roll once or twice a week during the summer. In February give a dressing of well-rotted manure, two tons will not be too much. Treat the Grass in the same way as an established lawn during the second year.

POTATOES AND CELERY ON DAMP GROUND (S. Rogers).—Flukes, Forty-fold, and Skerry Blues are good cropping Potatoes, and not so liable to disease as many others. They are late kinds. If you wish for early, then Ashleaf and Myatt's Prolifer; and for second early none is better than the Lapstone; but the best three are more liable to disease than the first three. The Pink-eyed Radical and the Early White Radical are large croppers, and not so liable to disease as many. You will succeed best by growing them on ridges, and they will crop better and not be so subject to disease, nor run so much to haulm in a wet season. The incomparable White Celery is an excellent kind, dwarf, stiff and close in habit, solid, crisp, and juicy, and it is the best late White kind. Manchester Champion Giant White Solid Celery is early, large, and the best White for size and flavour. Manchester Champion Red Solid is dwarf, very solid, and crisp, keeping well up to April, and one of the best kinds of Red Celery grown, if not the very best. Laing's Mammoth is large, solid, and not liable to run to seed. Cole's Defiance is also a large Solid Red Celery. On a wet soil growing the Potatoes on ridges is a good plan.

GRAPES IN JULY (Hem.).—To have Grapes in July the house should be closed by the middle of the present month, and for the first fortnight the temperature should be from 40 to 45; it should then be increased to 50, at the end of the second fortnight to 55, and in another fortnight to 60. On these temperatures allow a rise of 5 on dull days, 10 on those which are cloudy with clear intervals, and from 15 to 20 on clear days. All increase of day temperature should be accompanied by increased ventilation, corresponding in amount to the increase of temperature. The fires should be lighted and kept going whenever necessary to maintain the day and night temperatures. At first fire will only be needed on cold nights, but as the Vines advance it will be required day and night in order to secure the proper temperature, and to allow of the admission of air. You should not close the house and keep it closed without air, but daily open the ventilators, or lights, in the morning when the temperature from sun heat has risen 10 above the night temperature, and that will be 8 or half-past 8 A.M.; or if later give air, increasing it with the heat of the day. Close early or by the time the temperature declines. For instance; if the night temperature be 60, and by that is meant the temperature in the morning before the sun acts upon the house, you will give air at 70, increasing it to its full amount when the thermometer indicates 75, and if the temperature rise to 80 or 85, you have not too much air on, but if the temperature fall on the giving of air, then too much air is admitted, and the amount must be at once reduced. The air given should be reduced to a minimum when the heat begins to decline in the afternoon; say if the house is at 80, and the thermometer falls to 80, shut up the house.

WORMS IN FEBRUARY (P. Crowley).—The worms will make the soil very open and loose, and, besides, they will drag into their holes the fronds of the Ferns. A soaking of lime water will not injure the Ferns, and it will bring many of the worms to the surface, and these may then be cleared away. The soil in which these Ferns are growing must be deep, rich, and badly drained; it must also have too little stone in its composition to be suitable for the kind named.

EGGS OF ATLANTIC SILK WORM (H. H. M.).—Write to Lady Dorothy Nevill, Dangstein, near Petersfield.

SHIFTING FUCHSIAS INTO LARGE POTS (*Equos*).—You may pot your Fuchsias from five-inch into nine or ten-inch pots, which is no uncommon practice in Fuchsia culture. The objections to large shifts are, that plants grow more freely, have fewer flowers, and have not the stiff close-jointed habit of plants more frequently potted. Another objection is, that the roots make for the sides of the pot, leaving most of the soil unoccupied with fibres, whereas when the plants are only shifted from the pots become full of roots, every particle of soil is a mass of roots from the centre to the outside of the ball.

SOAPSTONES (S. N.).—You may apply this wash-house liquid to Rose trees whilst they are growing. We never heard of worms congregating where soapstones were applied.

ASPARAGUS FOR LONDON MARKET (*A Working Gardener*).—For the size you mention you might average *3d.* per 100 after deducting carriage, &c. The earlier in the season you could get it to market the more you would realise. The larger the better, and none should be sent less than 9 inches long.

ANTS (*A Lady*).—Water their haunt daily with ammoniacal liquor from a gas works until they disappear, which they usually do in a few days.

AN. ECTOCHEILUS DOMINI (W. Jackson).—It is a hybrid between *Goodyera discolor* and *Anacethechilus xanthophyllus*. The leaves are of a dark olive green, with a pale yellowish coppery tinge down the centre; the main ribs marked out by fine pallid lines, and the intervening spaces sparsely veined.

HYACINTHS BLOOMING BADLY (X. Y. Z.).—The bloom of the Hyacinths and Tulips being poor is in a great measure attributable to the inferior quality of the bulbs, although your treatment would not conduce to their blooming well. You excited them too much. A temperature of from 50 to 55 from fire heat is sufficient forcing, and the pots should have been placed on a shelf near the glass, and not in a bottom heat of 70. In other respects your treatment seems faultless.

PLANTING LILIES OF THE VALLEY (S. B.).—It would be much the better plan to take them up from the wood now and plant them in the border, preserving as many of the roots as possible. They would be much more likely to succeed in this way than if you waited until they were in bloom, and then moved the flowering plants only. The latter might or might not flower in the following year; most probably they would not, in consequence of their removal when in flower weakening the growth, so as to prevent the formation of bloom for another year. The blind plants one year are the most likely to flower in the next. You may now select the strongest, and if they have thick and plump buds or crowns they will mostly flower. The thin sharp-pointed buds rarely flower, but they are likely to flower well another year. A soil of two parts leaves, and of sand and loam, will suit them, but one-fourth more loam would be better in place of so much leaf soil.

NETTING (E. C.).—None is better for protecting fruit tree blossoms on walls than Haythorn's hexagonal netting, rather small-meshed.

BOTANY (*Economist*).—There is no cheaper work of the same kind as "The Treasury of Botany." Henslow's "Dictionary of Botanical Terms" briefly explains them, but nothing further.

SAWDUST FOR PLANTING POTS (H. M.).—Sawdust is a good material in which to plunge pots of cuttings, and the proposed mode of forming a hotbed over the hot-water pipes will answer very well. The temperature of the hotbed, if the pipes are kept warm, will be from 70 to 75, and that is sufficient. The temperature of the atmosphere should range from 60 to 65 at night, and from 70 to 75 by day; the place should be kept close and moist.

AZALEAS GROWING PREMATURELY (*A Subscriber*).—It is by no means uncommon for Azaleas to make young or new growths before flowering, and their doing so results from their being kept too warm, and from the buds not being well ripened in the previous season. This premature growth will not interfere with that subsequently made, and sometimes it does not materially affect the present bloom, but in other cases the flower-buds become abortive. Some varieties are more subject to this peculiarity than others, and it is chiefly confined to those carrying an extraordinary amount of foliage. These bloom as well with the new growths appearing as not; whilst those that are spare in foliage through the winter and start new growths early in the season, often have the buds abortive. We know of no remedy except to secure a good growth after blooming by a moist growing heat, to have the wood well ripened, and to keep the plants cool and well aired in winter.

TREES FOR NATAL (E. S. B. G.).—Almost any plant or tree that would succeed in the south of Italy would do in the middle terrace of Natal, but from the specimens of woods shown in the Exhibition of 1862 we should think that it would not answer to plant for timber. Yellow-wood may readily be procured in the colony in logs of 40 feet long and 5 feet in diameter; and though not durable when exposed to the weather, it answers well for in-door work. Sneeze-wood, which is produced by a species of *Pteroxylon*, is on the contrary very hard and durable; instances are known of its continuing sound in the ground for more than half a century. Besides these there are Stinkwood, and many other woods useful for furniture and wheelwrights' purposes. We think that the best varieties of fruit trees and vegetables would be a far more useful importation.

NAMES OF PLANTS (E. S.).—It is *Chimonanthus fragrans*, a native of Japan, introduced exactly a century since. It is hardy, though it flourishes better in a conservatory. (K. M. H.).—*Chimonanthus fragrans* (L. S.).—1. *Goldfussia isophylla*; 2. *Justicia flavicomis*; 3. *Sempervivum tortuosum*. (*Old Subscriber*).—The following Ferns were unaccompanied by numbers: *Adiantum tenerum*, *A. pubescens*, *Aspidium macrophyllum*, *Pteris cretica*, *Allorium rotundifolium*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending February 10th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun... 4	29.007	29.065	47	35	45	45	S.W.	.35	Overcast; rain; very boisterous, thunder, lightning, and heavy rain at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

HOW OUR POULTRY-YARD IS MANAGED.

I SEE in your Journal of December 12th that "J. S." asks how he is to obtain thirty eggs weekly, and I see you have given him very good advice respecting the breed and number of pullets he should keep. If you will allow me, I will state how we manage our small poultry-yard, as we have for the last eight or nine weeks collected as many as from ten to thirteen eggs per day from twenty-six fowls, chiefly Dorkings.

In the first place, we selected six good hens, chiefly Dorkings; we then crossed them with the Cochin-China, so as to have a little of the Cochin blood in the chickens, just enough to show that they had been crossed with that breed, and under the first two hens that will sit we put twelve or thirteen eggs each. We find that it is an excellent scheme to sit two hens at one time, as they will both hatch their chickens nearly at once, and then if there be a few eggs longer in hatching than usual, one hen will take the chicks, and the other will finish the hatching. Be sure to sit hens, and not pullets. If you choose you can put both broods together; for very often, and especially at this season of the year, you will seldom obtain a full brood—more likely six or seven chicks from each hen, and nothing, I think, looks so bad as a hen going about with two or three young ones. On the other hand, it is very pleasing to see a hen with a good brood—say fifteen or sixteen chickens—something for the hen to do.

I last year noticed several remarks made by persons visiting our place (I say our place, although I mean my employer's place; when a man makes use of the word "our place," it shows that he feels himself at home, and I think he takes more interest in whatever he may have under his care; but perhaps some employers may not like to hear their servants make use of the word); they would say, "What a fine brood of young chickens you have! How do you manage to hatch so many?" But the above are not all the advantages gained by sitting two hens at one time, for one of the hens can be shunt up for a few days till she forget her young ones, and in a little time she will recommence laying. I find that hens crossed as I have already stated turn off their young sooner than some other sorts, besides being first-class hens to sit.

As a rule we never kill any of our early pullets, although we are sometimes forced to do so; we generally kill all cockerels, except when we see a promising young bird, and then we save him. The young pullets lay plenty of eggs for Christmas. It might be supposed that our stock must increase very fast, but we generally sell or kill as many old hens as we save pullets, never keeping a hen longer than four years, unless she has some good quality, and then she has a reprieve. A new young cock should be introduced every season; it is a good plan to import some fresh blood into the stock every year.

Now, as regards food. Perhaps it will be said the chickens must live well. I will admit that they do; they have plenty, not enough to waste. I have seen some men take a gallon or peck of corn and throw it all out at one time on the ground, whether the fowls wanted it or no. Now this is very wrong

and very wasteful—nothing looks so bad as a quantity of food lying on the ground and the fowls running over it. It is, as I have said, very wasteful, and, besides, it makes them very dainty. They should have no more food than they will eat up. The person feeding them can by careful observation tell how much fowls will eat; sometimes they will eat more than at others. If the atmosphere is moist they can find more worms, &c., than on cold dry days, and they then require less corn. Our twenty-six fowls generally eat about three quarts of maize per day, three pints are given them in the morning and three pints about two hours before roosting-time, and when the man feeds the pigs he generally gives a little food out of the pail; they very seldom have any bits from the house. They have a very good run, plenty of vegetables to eat, and sufficient room to clean themselves.

I should advise "J. S." to do as we do when eggs are dear, which is generally about Christmas—viz., give extra food, say a little groves and barley-meat, and they will lay more. Always keep the fowls as warm as means will allow, and when eggs are cheap feed only on maize or barley, I prefer maize, and let them go off laying for a time as a sort of rest-period. I keep fowls for profit, and not for a hobby only. I think if "J. S." will attend to the above simple mode of treatment he will be sure to obtain the number of eggs required.—J. R. P. *Bickley*.

THE POULTRY CLUBS NATIONAL SHOW.

I WENT with my birds on the Wednesday evening, and saw them placed in the Show, no person except officials being admitted. I then saw by the hand-bills that the public would be admitted at three o'clock on Thursday. So I went about that time, and found a few exhibitors like myself waiting for admittance. While standing and talking to some friends I heard some one say, "There are some Pigeons lying about inside." I turned round and saw that they were my Spots, at least I had a very great suspicion that they were mine. The doors opened at last, and I bought a catalogue—looked for the number of my Spots, went to the pen, and found only one there. I asked one of the attendants where the other was. He said it was upstairs, and would be caught when the gas was put down, so I did not trouble any further, for I knew such accidents would happen in the best regulated Shows.

Well, I went on looking at the several pens until I came to my Fantails, and found to my disgust that some one had nearly pulled the tail feathers out of both of them, for when I packed them they were quite perfect.

But matters did not end here. Other fine pairs had shared the same fate; and in going a little further on, I next detected that some one had wantonly plucked the frill out of my Turbits, and left the skin completely bare.

I made a complaint to one of the Committee and he said it was a pity, but he said he was certain he did not know who had done it.

Now, this mischief must have been purposely done, and by an interested party too—for I heard that the feathers were all found in a corner. Who it was that had been so malicious I do not know. There is no wonder that fanciers should give up the fancy so soon when persons perpetrate such acts as the above. I have shown at a great many shows in England and Scotland, but never saw birds in such a state before.—JOHN THACKRAY, *York*.

I HAVE just received my birds 6 p.m., Wednesday 7th, from the late Rochdale Show, and certainly think it an unreasonable time for transit (104 miles), as the Exhibition closed on Monday. Nearly all the tail feathers of my two pairs of Fantails have been pulled out. I am also informed by a gentleman who visited the Show, that these Messrs. Thackray, Emberton, and Robinson have likewise been treated in the same heartless, cruel, and distasteful manner; in fact, my birds are so badly disfigured that I cannot possibly recognise them. As it is well known to all Pigeon fanciers that some seven or eight weeks must elapse before the tails can be reproduced, of course it prevents all chance of exhibiting them in the meantime. I should feel much obliged by any suggestion of your own in this matter, or from any correspondent of the Journal. I certainly do not intend, so far as my own personal trouble and expense are concerned, to let the matter sleep, if by any means the offender or offenders can be publicly exposed and duly punished.—H. YADLEY, *Market Hall, Birmingham*.

GAME BANTAMS.

As a breeder of Game Bantams, I must express my great surprise at "WILTSUMMER RICEON'S" avowal in answer to "GARRUS," that Black Reds are easy to breed for, of course, he means easy to breed good. Now, I aver the contrary. I say positively and distinctly, that it is most difficult to breed many first-class birds, however many may be hatched and brought up. I have for several years bred Game Bantams. In 1864 I reared upwards of 100, and in 1865 nearly 150; therefore, I am not talking at random. In 1864 I bred from a bird, bought of Mr. Kellway, which had proved his goodness by winning wherever shown. I put him to hens bred from Canser's, Harvey Bayley's, and Forrest's strains. Two of these hens were first at the Crystal Palace, and yet I am sure I am within the mark when I say that not more than ten of their chickens could be called first-class. In 1865 I bred from Mr. Kellway's second prize Birmingham cock, said by him to be one of the best birds he bred in 1860, and Mr. Munn's Kendal cup bird (1865), and my hens were the pick of the chickens of 1864, and two hens with which I won the first prize at the last show but one at Islington (for these hens when pullets Mr. Kellway offered me any price that I liked to ask him, and yet I am sorry to say I had not out of all my chickens more than half a dozen cocks and two pullets that could be fairly called first-class birds. Now, if this does not show that it is not easy to breed good Game Bantams, I should like to know what would prove it.

I think "GARRUS" very fairly asks how it is that first-class birds fetch such a price if they can be so easily bred? "WILTSUMMER RICEON" instances the tulip mania, but he is much too wide awake, I am sure, not to see on reflection that that has no analogy with the present case. The tulip mania was a mere gambling affair, many roots of a particular flower being sold at fabulous prices, when, perhaps, only one root of it was really in existence, and the bulbs did not, I believe, in the great majority of cases pass from seller to buyer at all, but were sold to be delivered at a distant date, which never came. Now, if high prices are given for Game Bantams by a good judge of them, it is scarcely credible that he could do this if he could obtain equally good birds cheaper elsewhere. If, on the other hand, these high-priced birds are bought by those who do not understand the essential points of the breed, it really proves nothing but the ignorance and folly of the buyer, I know of £10 having been recently given for a pair of pullets by a gentleman, who, I am sure "WILTSUMMER RICEON" would admit, knows what a Game Bantam should be. I have been offered £10 for a cockerel within the last ten days by a gentleman who is known to possess one of the best strains of birds in the kingdom, and if I am not misinformed, Mr. Hawkesby has been offered £15 for his really splendid little bird which was first at Birmingham in December last. I would give him £10 for it any day.

In the face of these facts can it be contended that Black Reds are easy to breed? Is it not in fact reasonable that they should not be? The breed has not only been in existence from eighteen to twenty years, and I should think is most probably the result of a cross, perhaps that of the old Naoken Bantam with the Game cock. Hence the breed has not yet attained that fixity which other well-known and long-established breeds possess, and the tendency to throw back is very strong. The fact is, however, that it is not easy to breed first-class birds of any variety. I have been a Spanish fancier for many years, and I am sure breeders of that splendid fowl will bear me out when I say that not one chicken in ten comes first-rate. In short, all breeders know well that good birds of any fashionable variety always command a high price, simply because they are difficult to breed.—P.

DRAGONS WITH WHITE RUMPS.

IN No. 247 of THE JOURNAL OF HORTICULTURE Mr. Percivall makes some remarks on Dragons with white rumps being useless as prietakers. For the information of the Birmingham Columbarian Society, of which I am a member, I will thank you, or Mr. Wells and Dr. Cottle, to say if Mr. Percivall's remarks are "patent," inasmuch as the same birds that Mr. Percivall alludes to were shown at Manchester, judged by the same Judges, and the awards were not only reversed, but the prize birds at Birmingham did not even receive a notice. If Dragons with white rumps have gone out of fashion, it will be of the greatest importance to the members of the Birmingham Columbarian Society to know, many of them being breeders of Dragons.—C. B.

RAILWAY CHARGES.

THE first of the two suggestions by "Y. B. A. Z.," which appeared in your issue of January 23rd, I consider decidedly the better and by far the more practicable. The Poultry Club should, I contend, take the matter up with the railways, and I do not see a better plan than by petition. Some amount of trouble and inconvenience must attend it, but in that I shall be happy to bear a share. "Our Editors" are in possession of my name and address. If any one should feel disposed to communicate with me, it can be done through them. Not being yet a member of the Club, I can do very little more.

With regard to "expense," I believe that we are urging a reduction of railway rates to save the pockets of exhibitors from what we, the poultry exhibitors, consider unjust charges, at the same time generously taking into consideration the benefit of railway companies who convey our poultry, and not forgetting the extension of poultry exhibitions, and the same being made accessible to a class who at the present time cannot show their specimens simply because of the various "expenses" attending it, the most grievous being, perhaps, "railway charges." But why make it more expensive by devoting some part of our incomes to the attainment of the object in view? I must confess I cannot clearly understand this, and, not understanding, think it decidedly unnecessary. Is it not making bad worse? I am open to correction on this point, being but a young exhibitor and totally unacquainted with the rules of the Poultry Club. Now, I would add to "Y. B. A. Z.'s" recommendation, that the Poultry Club advocate in their petition—that is, if they will consent to take the matter up, that exhibition poultry be conveyed to and from places of exhibition at the ordinary rate of parcels. This would reduce the expense considerably, for, as I stated in a previous letter, the rate for conveying poultry is 50 per cent. more than for parcels, or half as much again. I think this proposition would be more readily listened to by the railway officials, for, having unsold specimens returned free is open to much confusion and dishonesty. We must give the companies as little trouble as possible, and I would also point out to them the advantages to be gained on both sides.

If these suggestions are considered of any service, I shall be happy to place myself in communication with the Secretary of the Poultry Club (a member of which I hope shortly to be), and at all times shall be only too glad to render any assistance that may lie in my power for the benefit of poultry exhibitors, and poultry shows.—F. H.

It was my intention to have commenced the campaign with the London and South-Western Railway. This is the railway that I mentioned in a previous Number as always charging the return journey but repaying it on application, so that I was not surprised to see "J. De L. S.'s" communication on the subject. Your next correspondent, "P.," however, would be astonished how crotchety some companies are on the point he alludes to. I know a company that for two years allowed this privilege, and when the committee, taking it for granted, printed it the third time in the regulations before they asked, making sure that there would be no difficulty, the boon was refused! I have no doubt that if all secretaries made it a point to apply, railway authorities would begin to see that it was a grievance.

The plan suggested by "CANTUS," that six gentlemen should form a deputation to the various railway companies, is a very good one, if they can be found. This could be done in addition to the Poultry Club, and a petition by breeders independently of the Club; and it would be a great thing for the deputation to be able to say, "We represent the whole of the leading exhibitors, as proved by these signatures."

A uniform rate by all railways would be capital could it be managed, and if printed and sent to each exhibitor and station-master, prepayment would be an easy matter. At present it is a great source of inconvenience and annoyance, as some of my correspondents have already shown me, and as I have felt myself.

Another correspondent has mentioned to me that one railway will take birds by the longest possible way to make the carriage come heavier, and monopolise it for themselves. This is very unjust.

In conclusion let me urge all exhibitors to take the matter up together. "Our Editors" have kindly consented to act as treasurers of the independent fund, and, I believe, the Poultry Club have begun to move in the matter: but we may act independently of each other with better effect. If, how-

ever, we are to do anything with a petition we must start the matter at once. Several exhibitors have written me, saying they will sign, putting down their names for 10s. *gd.*, and some guaranteeing more. The former sum would not be felt much by any of us, and would form a handsome total, whilst, if we are successful, its repayment will be rapid. I hope next week to give a list of those who have promised their help; meanwhile, I shall be very glad to hear from others, and, perhaps, it will simplify matters and save postage, if I sign myself—JOSEPH HINTON (Y. B. A. Z.), *Hinton, near Bath.*

MIDDLETON ORNITHOLOGICAL SOCIETY.

THE first Exhibition of this Society was held on Friday and Saturday last. The following is the prize list:—

CANARIES.

NORWICH (Clear Yellow).—First and Second, G. F. Welch, Wilson Hall, Derby. Highly Commended, W. Walters, Winchester; J. Moore, Northampton. Commended, J. Wynne, Northampton.

NORWICH (Clear Buff).—First, G. F. Welch. Second, W. Walters. Highly Commended, J. Bennett, Derby; W. Walters; J. Moore. Commended, G. Cummings.

NORWICH (Crested or any other variety).—First and Second, W. Walters. Commended, J. McMillin, Great Percy Street, Pentonville.

BELGIAN (Clear Yellow).—First, W. Phillips, Old Basford, Nottingham. Second, R. E. Ashton, Oakland, near Bury.

BELGIAN (Clear Buff).—First, J. Horrocks, Blackley. Second, W. Ogden, Middleton.

CRESTED BELGIAN (Any colour).—First and Second, H. Barlow, King Street, Oldham. Highly Commended, A. Hamer, Oldham. Commended, R. E. Ashton.

LIZARD (Golden-spangled).—First and Second, A. Hamer. Third, S. R. Stanley, Manchester. Highly Commended, G. Cummings, Southgate Street, Gloucester; R. E. Ashton; J. Tattersall, Oldham.

LIZARD (Silver-spangled).—First, A. Hamer. Second, R. E. Ashton. Third, J. Tattersall. Highly Commended, J. Tattersall.

MULE (Jonque Goldfinch).—First, Second, and Third, D. H. Noar, Cannon Street, Manchester. Highly Commended, E. Horsfall, Manchester.

MULE (Mealy Goldfinch).—First and Second, D. H. Noar. Third, E. Horsfall. Highly Commended, W. Walters; W. L. Chapman, Northampton.

MULE (Lionet).—First, H. Manners, Lower Broughton, Manchester. Second, A. W. Booker, Allerton, near Liverpool.

MULE (Canary, any variety).—First, W. Walters. Second, W. L. Chapman.

ENGLISH BIRDS.

GOLDFINCH.—First, C. H. Fisher, Stroud, Gloucestershire. Second, H. Ashton. Highly Commended, A. Hamer.

LINNETS.—First, S. Reynolds, William Street, Derby. Second, J. Tattersall. Highly Commended, G. Cummings.

SKYLARKS.—First, A. Hamer. Second, R. Wolstenholme, Linfield, Bury. Highly Commended, W. Walters. Commended, J. Turner.

TITMUSH.—First, Mrs. Bagnall, Middleton. Second, J. S. L. Beaufort, Prestwich.

FOREIGN BIRDS.

PARROT (Green).—Prize, A. W. Booker. Commended, J. Heaton, Middleton.

LOVE BIRDS.—Prize, H. Ashton. Commended, W. Walters.

GRASS PARAKEETS.—Prize, H. Ashton. Highly Commended, C. H. Fisher; J. Jones, Manchester.

ANY OTHER SORT OF LARGE FOREIGN BIRDS.—Prize, A. W. Booker (King Lory). Highly Commended, W. Walter (Puffin Bullah).

ANY OTHER SORT OF SMALL FOREIGN BIRDS.—Prize, H. Ashton, Prestwich. Highly Commended, H. Ashton; R. E. Ashton, Oakland near Bury (Brisbane Finch); W. Walters (Saffron Finch). Commended, W. Walters (Madagascar Bird).

PIGEONS.

CARRIERS.—First, C. & E. Roys, Great Hill, Rochdale. Second, J. R. Robinson, Nile Street, Sunderland. Commended, J. Frith, jun., Dewsbury.

ALMOND TUMBLERS.—First, J. Fielding, jun., Rochdale. Second, J. R. Robinson.

TUMBLERS (Any other variety).—First and Second, J. Fielding, jun.

BARBS.—First, J. Frith, jun. Second, H. Beldon, Bingley. Highly Commended, J. R. Robinson.

JACOBS.—First, C. & E. Roys. Second, H. Beldon. Highly Commended, A. Middleton, Newport, Mon.

FASTAILS.—First, C. & E. Roys. Second, H. Yardley, Birmingham.

OWLS.—First, C. & E. Roys. Second, J. Fielding, jun.

DRAGONS.—First and Second, H. Yardley.

BALDS AND BEARDS.—First and Second, C. & E. Roys.

TRUMPETERS.—First, H. Beldon. Second, C. & E. Roys.

TRIFTS.—First, R. Thompson, Kendal. Second, H. Yardley. Commended, H. Beldon.

ANY VARIETY.—First, C. & E. Roys. Second, Countess of Derby, Knowsley Hall, Prescot (Isabel). Highly Commended, C. & E. Roys, H. Yardley; E. Brocrid, Loxwood, Kent (Siberian Ice Pigeon).

JUDGES.—Mr. A. Evans, 85, Chapel Street, Salford; Mr. J. W. Edge, Aston New Town, Birmingham; Mr. G. J. Barnesby, Derby.

POLLEN-GATHERING IN SCOTLAND.—Bees first seen pollen-gathering at 3 P.M. this day (January 25th) upon flowers of early striped yellow Crocus and *Jasminum nudiflorum* in front of my house. In addition to Snowdrops, Christmas Roses, Primroses, Hepaticas, *Arabis alpina*, &c., as spring flowers, we have, through the mildness of the season, autumn Stocks, Wall-flowers, and some fair buds of China and Hybrid Perpetual Roses still in bloom.—I. WEBSTER, *Gordon Castle.*

APIARIAN NOTES.

(Continued from page 82.)

Is resuming the account of "My Apiary." I now propose referring to the pages of my note-book, and jotting down a few leading particulars of the results of the year's operations. I take each hive in order, as numbered below.

No. 1.—One of the hives attacked by dysentery, strengthened by the union of bees and brood-combs from another sufferer, No. 19. A large frame-box super was put on, in which the bees, so long as it was allowed to remain, worked admirably. This was removed, prior to being completed, on June 19th, as the hive was required to furnish bees for a large artificial swarm. The hive was transferred to another stand in the same garden, and a great number of the bees left it for the new hive substituted for it. Notwithstanding the enforced diminution, this stock threw off a large natural swarm on the 22nd, three days later. No further honey was obtained, but it is now one of the strongest and most populous hives that I have.

No. 2.—On the 29th of May, while observing No. 18—a Ligurian stock, with a beautifully pure Italian queen—a large swarm suddenly poured out from it, and the bees appeared to fly right away without attempting to settle anywhere. After a long period of suspense they were discovered in the act of clustering at a considerable altitude on a large beech tree growing in the garden of our right reverend diocesan, on the top of the old city wall. To reach the swarm at all was a matter of very great difficulty, as it hung suspended from the end of a long and flexible branch; but it was at length happily and successfully temporarily secured in a common straw hive, and was permanently domiciled in a large bar-and-frame-box.

On the 8th of June this box was nearly filled with combs, and on the 19th it was deprived of all save one, on which, after a search, a queen was found. This, with the bees and her majesty, was placed in an empty hive on the stand previously occupied by the swarm. All the bees were shaken or brushed off the remaining combs, and were left to furnish a new habitation, while the combs which had been taken away, and which contained splendid masses of brood in every stage, were restored to the now tenantless box. No. 1 having been removed, as before stated, this hive of brood-combs was located in its place; a large population at once took possession, and numerous royal cells were in time constructed. From these several small nuclei were supplied with one or two royal cells, and small artificial swarms, in order to increase the number of my Ligurian stocks, were started; but I was not very fortunate in obtaining pure breeding queens, owing to the immense number of common drones in my own and the adjoining apiaries.

No. 2, the pillaged swarm, containing the original Ligurian queen, refilled its hive with combs, but required copious feeding in the autumn.

No. 4.—An octagonal box hive, in which all the bees died in the winter. On the 21st of May bees were observed flying in and out, evidently reconnoitering, and preparing the hive for the reception of a swarm. I cut away a great deal of bad comb, and removed the dead bees, leaving the hive on its stand. On the 28th a swarm rose from a hive on the opposite side of the lawn, and without any previous attempt at settling, flew right across to this box. A most curious sight was presented; the hive seemed a mass of moving insects, rolling over and over each other, and tumbling in large clusters to the ground. It was a long time before all the bees could effect an entrance through the contracted doorway. When quite settled the hive appeared crumpled, and I resolved to put on a super as soon as possible; but, unfortunately, this apiary being in the country, I had none then at hand. On the 30th, before I could again visit this apiary, to afford the required accommodation, No. 8 threw off a swarm, which pitched on an espalier tree, not far from No. 4, the bees of which sharing in the excitement rushed out of the hive and clustered within a few yards of the other. Both swarms were secured in separate receptacles; but in a quarter of an hour that from No. 4 suddenly left, and the bees tumultuously joined with those of the swarm from No. 8. All the bees were in the evening transferred into a large-sized frame hive, which they appeared to me more than till, so vast were their numbers. I may have to notice this hive further on, but now return to No. 4. A few of the bees did not go off with the rest, and these, with returning stragglers, formed a very diminutive cluster. It was doubtful whether the old queen was left behind, or whether the bees were engaged in rearing royal larvae from the eggs which had been deposited by her before the desertion took place, as they appeared to work steadily,

carrying in pollen as well as honey. On the 8th of June a second swarm was added, leaving the queens to chance, and the hive having been previously tolerably full of comb, a very nice stock is the result.

No. 5.—A frame hive on which a super was put in May, in which the bees at first worked vigorously. A very fine swarm was thrown off, which clustered in the top of a high fir tree; before proper means could be taken for securing it, the bees rising suddenly flew off in a straight line to a wood more than a mile distant, where, though followed as quickly as possible, they were utterly lost sight of.—S. DEAN FOX.

(To be continued.)

OUR LETTER BOX.

PECUNIARY EGGS (*Chalcids*).—In Turkey the whole of the eggs of the season are fecundated at once, and so, probably, are those of other poultry.

ARTIFICIAL HATCHING (*G. M. P.*).—The temperature generally must be 104° or 105°. It may be allowed to fall to 95° once a-day for half an hour, as when the hen leaves her nest. If you send four postage stamps to our office with your directions and order No. 197 of this Journal, New Series, you will find there a drawing and directions for treating the chickens.

EGG WITHIN EGG (*T. Bottomley*).—It is not a very uncommon occurrence. The cause is explained in "The Poultry-keeper's Manual," just published at our office.

DUCKS (*G. B. C.*).—Barlymeal mixed with milk is as good food as any for Ducks to be exhibited. The characteristics of Roman Ducks in "The Poultry-keeper's Manual" are those which constitute excellence.

ELEGANT PAIR OF SPANISH COCK. *J. B.* has a Black Spanish cock which has a hard yellow substance on the white of his face and ears; it is light yellow at first, and then becomes darker, and hard like a scab, and very fast to the ear. If pulled off it soon grows again and becomes larger than before.

[There is no hope of your Spanish cock recovering. He may serve you to run with the hens during the season if you have no other. He has the bad face to which Spanish fowls are alone subject, and for which there is no cure known.]

POULTRY DISEASES (*Doyle*).—You do not tell us in what state the other viscera were, whether the liver or intestines were ulcerated. The darkness of the comb, the food remaining long in the crop, and the flow of liquid from the throat, may arise from torpidity of the digestive organs. Give each bird daily a dessert-spoonful of brandy; feed on soft food, and give bread soaked in ale once a-day until health is restored. We should be obliged by your letting us know the result of this treatment.

PIGEONS. *S. J. C.*—Your yard (6 feet by 9), would be too small for even twenty Pouter. If you can breed a pair of Rants to match of 5 lbs. weight, or nearly so, you may make tolerably sure of many prizes. Rants are not generally considered good breeders. For that purpose a cross between Pouters and Dragons would give more satisfaction, or any of the large mongrels. By "Blue Rock" I suppose you mean the common Dovecot Pigeon; they are sharp-flying birds, and no doubt if trained would fly long distances. Two Pigeons out of one nest will breed together, provided they are cock and hen; but it is not generally advisable to pair them, the young in such cases being rather more delicate.—B. P. BURNETT.

GOLDFINCH NEST BREEDING (*C. Stubbins*).—Goldfinches breed about May. You may put the Goldfinch and Canary together in April. Let the cock have possession of the cage, and when he sings stontly put the hen along with him. The cock Goldfinch sings louder and is brighter in colour; he has more black on the tip of the beak, and is blacker on the cap. The hen is often grey at the corners of the mouth, and blacker on the shoulders of the wings. They pair almost as readily as Canaries. Canaries may be cycled this month, but it is better to wait a month or six weeks longer.—B. P. BURNETT.

WOOLLY HIVE (*St. Norice*).—1st. Bees will sometimes survive the winter in exposed wooden hives not more than an inch thick, but they cannot be safely kept in this way. Under no circumstances should the hive itself be painted. 2nd. The opening in the adapter may be half an inch wide, and some apiarists prefer their running across the bars instead of from front to back. They should then, however, be at the front and back, and on no account across the hive's centre. 3rd. It is most convenient to have a swarm in the first place in a common straw hive. As soon as it is settled spread a cloth on the ground, on which stand the frame-hive without its floor-board, and the front raised an inch or two. Then knock out the swarm on the cloth close in front of the hive, towards which a stream of bees should be gently directed by means of a feather. As soon as all, or nearly all, have entered, the hive may be stood on its floor-board, and put in the place it is intended permanently to occupy. Or, if the frames are well furnished with guide-combs, the crown-board may be removed, and the swarm knocked out on the top of the exposed bars, between which the bees will rapidly disappear, when the crown-board may be replaced and the hive put on its intended stance. 4th. An adapter is essentially necessary, as without one there would be little chance of breeding being confined to the stock hive, and the combs would be so commuted that much loss, both of life and honey, would be caused by removing the super. 5th. The only entrance should be in the stock hive. 6th. Equal distances between each, which will be found to give a space slightly in excess of half an inch. 7th. There is no objection to allowing the bees to commence in a super 1/2 inches deep, and then raising it on a square frame of the same depth; but it would cause them much loss of time if the two were divided so as to compel them to commence a new set of combs afresh from their foundations.

A GOOD BEE-HOUSE (*St. Norice*).—It is probable that in the bee-house described in page 223 of our last volume, it might be found convenient to have both the roof and back attached to the house itself by hinges, as suggested by you, instead of being entirely detached.

GOLD AND SILVER FISH (*G. P.*).—We know of no other place than in the conservatory or Covent Garden Market.

PRESERVING COOKED MEAT (*H. R. Hills*).—Cooked meat is preserved "as long as possible" in tin cases, soldered, or whilst the meat and tin are hot, as to expel the air as much as may be.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 46.2°; and its night temperature 32.1°. The greatest heat was 58°, on the 21st, 1859 and 1846; and the lowest cold 15°, on the 24th, 1830. The greatest fall of rain was 0.92 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

THE GROWTH AND MANUFACTURE OF TOBACCO FOR FUMIGATING-PURPOSES.

VERY often questions are asked about the best and cheapest mode of destroying insects in horticultural structures; and, on the score of cheapness, tobacco paper and other inventions are recommended. After all the patent preparations there is nothing that can rival Tobacco for fumigating-purposes; but the question of expense is a consideration where plants liable to the attacks of green fly are grown on an extensive scale. For a house of moderate dimensions little less than a pound of shag tobacco will prove ample, and then the dose should be repeated once or twice afterwards in order to prove effectual in the destruction of the insects which survive. This item will in the course of a year prove considerable, and add a rather large amount to the expenses of the garden. Now, in order to overcome this expenditure, for several years I have given attention to the growth and preservation of Tobacco, and I have found by care in its proper preparation that the home-grown is quite equal to the best Tobacco procured from the tobaccoists. The kind I use for this purpose is the *Nicotiana tabacum*; it was introduced into this country about three hundred years ago by Ralph Lane, and either brought from Tobago in the West Indies, or Tobacco in Mexico, whence it derives its name.

In the southern counties Tobacco will vegetate in the open ground without artificial assistance, but in a cold district like this it is necessary to raise the plants in a little heat. One or two pans are sown, according to the number of plants required, about the middle of April, and by the second week in May the young seedlings are ready to prick-off into small 60-sized pots. They are then allowed to remain in heat until they become established, and are hardened off by degrees. By the time the first crop of early Potatoes from a warm border is taken up, which will be in the third week in June, the Tobacco plants will be strong and robust, and ready for transplanting. The ground is then forked over, and a quantity of manure applied, as Tobacco is a gross feeder, and a great exhauster of the soil. The plants are then placed about 2 feet apart, and if the weather happens to be dry, they are watered about every other day to give them a start.

By the middle of September the plants are 5 or 6 feet high, when the lower leaves are gathered, and either tied in small bundles, and suspended from the roof, or laid on shelves, in an early vinery to sweat and dry. We keep collecting a quantity of leaves at intervals till the plants have done growing, when all that are left are gathered, with a portion of the summit of the plant. As soon as the

first-gathered leaves are sufficiently dry they are stored away in large pots or boxes, packed quite solid, and put away in a dry place. Care must be taken not to store the leaves away too soon while they are surcharged with moisture, otherwise they will decay, and lose their peculiar principle. When the Tobacco is required for use, we cut it into chaff-like shreds with a sharp knife. If a large quantity were required a chaff-cutting machine might with advantage be employed. The produce of about seventy plants supplies all wants throughout the year.

The plan adopted for fumigating is very simple, and what some of your fast-going readers might say rather old-fashioned; it is the system which I learned in my early days, it answers very well, and until I discover a better I shall adhere to it, though it certainly is not the most agreeable. An eight-inch pot is employed; near the bottom is made a hole large enough to receive the nozzle of the bellows, a few red hot cinders are put in the bottom of the pot, and over the cinders a good quantity of Tobacco. The pot is then carried into the house which is to be fumigated, and air is gently blown by the bellows, through the hole in the bottom. Care is taken to keep the Tobacco equally distributed over the cinders, to prevent the Tobacco-dust escaping from the pot. A few minutes will suffice to charge the structure with smoke so as to destroy insect life. I have never discovered any injury to the plants arising from this simple method, except on one occasion. Some shrubby *Calceolaria* plants had been taken up from the borders in the autumn to supply a few cuttings in the spring. The house in which they were kept was rather too warm for them, and the atmosphere was charged with a superabundance of humidity; the young foliage being, as might be expected, very tender, the first sunny day after the house was smothered some of the young leaves turned rather brown, but not so much so as to permanently injure the plants. Some place a little moss over the Tobacco in the pot, this is good plan when there is any danger of the cinders being too hot.

When the young shoots in the orchard-house become infested with the green aphid, which rarely occurs, we put a handful or two of Tobacco in a vessel, and pour over it a quantity of boiling water; the young shoots are dipped in the liquor when cold, and it is quite effectual in destroying the insects. This I consider a simple and effectual way of destroying insect life, and not to be despised because of its simplicity. It is worthy of the attention of amateur cultivators of plants, that the Tobacco in its growing state is rather ornamental than otherwise.

While on the subject of Tobacco, I would caution my younger brethren of the spade against the inordinate use of this poisonous narcotic. The habitual use of tobacco, like many other stimulants to which man becomes a slave, may appear for a time harmless, and is thought under certain circumstances advantageous to the human system. The essential oil of tobacco acts directly on the brain and nervous system, and applied to a wound has been said by good authorities to prove as fatal as the bite of a viper. The oil, given to pigeons, has been known to cause vomiting and death. For a time the use of tobacco might be resorted

without any apparent evil, after its first stupefying effects are overcome; but its moderate use is followed by disease of the liver, nervousness, constipation of the brain, paralysis, loss of tone of the digestive organs, and disease in various forms. It may for a time excite the excited nervous system, but only to render it more irritable and feeble afterwards. A person who smokes much may generally be distinguished by a pallid countenance, defective breathing, defective action of the heart, impaired energy, and loss of sight. In thousands of cases these evils follow an injudicious use of tobacco. QUINTEZ BRAD, *Lubbock, Tex.*

THE LATE SNOWSTORM AND ICE KEEPING.

I am glad that Mr. Fish has directed attention, at page 109, to the storing and keeping of ice; while in the same Number Mr. Perkins suggests the use of machinery to crush it before putting it into the ice-house; and although at present (February 17th) there seems to be but little chance of any of these things being brought into practice this season, discussion may be of useful information as to the best mode of keeping ice.

Those who were successful in securing a quantity of ice at the close of the snow-storm in January, may consider themselves fortunate, for I can assure Mr. Fish that he was not alone in being unable to obtain any. The storm here was more remarkable for the depth of rain and snow than for the intensity of the frost, so that there was scarcely any ice. The days preceding the snow-storm were fine and even mild, the 9th and 10th of January dry, without frost, and with much less wind than before, but the falling barometer indicated that some thin clouds or showers of which the heavens gave no token, so far as most people could discern. For myself, I confess to not being gifted as a weather prophet, but another class of beings were evidently better judges. The birds, which for several days prior to the 10th had been singing with all the melody of an April morning, scarcely gave out a note on that day, although the air was clear and the thermometer about 50; but there was very little indication of frost, and I believe it was not until the snow had fallen in large quantities that the thermometer fell to 32, and subsequently to 30. The snow was preceded by a very heavy fall of rain, commencing soon after midnight, and at daylight sufficient snow had fallen to hide the ground, a thin film of snowy water covering the surface of small pools. The snow, drifting with a north wind, kept falling throughout the day, so that by the night of the 11th some roads were impassable. A sharp frost set in after the snow ceased, but the temperature evidently fluctuated very much, for although the thermometer indicated as low as 18, the ice on exposed pools was only half an inch thick. The 12th was mostly fair, but the thermometer seemed to alternate between a thaw and frost, and at night there was a clear sharp frost. This, however, had not been continuously severe, for the ice on the following morning was barely an inch thick, and that only in particular places, and a thaw setting in ice could not have been kept in any quantity without being much mixed up with dirt. Rain falling early in the forenoon and continuing all day rendered ice collecting inadvisable; for it would not only have exposed men and horses to the inclemency of the weather, but the ice seemed would have received large accessions of mud, which in the best of times finds its way into the ice-house in greater quantities than is desirable, and I have no doubt hastens the decay of the ice.

The amount of rain and snow which fell on the 13th exceeded the amount on any single day in 1865, being 1.35 inch. The 8th, however, of the two preceding nights probably defied the melting of the snow, otherwise some disastrous effects would have occurred. As it was, the river Mississippi rather than it had been for upwards of twenty years, and the rain water being mostly carried off before the snow melted, the soil was polished rather than increased, and the rainfall of the 13th added to the supply. Such was the quantity, or rather the wintry period, of the middle of January, that it is hard to believe that since we may be so fortunate as to experience a long green and mild autumn there never has been a winter so early and so prolix as this, &c. One or two of the most remarkable specimens of the remarkably fresh and verdant state of the sprouts and plants had not been in the least injured by the storm, and were absolutely in a growing state. They were, however, killed by the frost and snow, and have since become mould.

The above are the only notes on this subject which connection with ice-keeping are here only given with a view to show the

impossibility of obtaining in quantity ice of a kind that is likely to keep, as it rarely happens that it can be taken direct from the pond and put into the ice-well in a clean state; and its contact with the ground during a thaw results in more or less mud becoming attached to it, and although the ice wastes fast enough, the dirt all remains. Even when the greatest of care is taken, and the ice and the weather are all that can be desired, a certain quantity of mud always finds its way into the ice-house, and in summer the upper surface of the ice will be found covered with mud, and this evil is still greater when the ice has been secured in a dirty condition. Weeds in the pond from which the ice is taken, as well as tree leaves, sticks, and other rubbish, although they form but a small item in the sum total at the time of filling, all help to augment the casing of dirt and to create wonder among the inexperienced how such matters came there. The keeping of ice, however, depends on so many circumstances combined, that it is no wonder that there is so much difference of opinion as to the proper mode of securing this luxury, and as it contains within itself some of the causes of its decay, a glance at these will enable us to judge with more accuracy the means likely to arrest that decay.

It cannot have escaped the notice of the most careless observer how much lighter ice is than water, taken bulk for bulk. I am not prepared to say how much lighter it really is, but believe it must be nearly 20 per cent., and as pure water weighs 62½ lbs. to the cubic foot, I will suppose that ice weighs about 50 lbs. Now, if a cubic foot of ice be deposited in a place prepared for its reception, it contains within itself about 300 cubic inches of air, and as it is impossible in practice to obtain such blocks of solid ice, breaking such as there are, and their storage in a rough state, must increase the quantity of air contained in the mass. If that air could always be kept at a temperature below 32, no wasting would take place; but as this cannot be done, the question is how to displace as much of that air as possible, and render the lump as dense and solid as it can be made. To effect this object is by no means easy, for the very process of freezing is accompanied by an expansion of the water that is congelated, and a large percentage of air is included in the ice. I believe that ice of unusual thickness—say 5 or 6 inches or more, is more porous than that which is thinner, clear ice about half an inch thick, or thereabouts, being in my opinion the most dense; but the benefits of ice of this thickness are more than counterbalanced by the difficulties in obtaining it and other attendant inconveniences. It has not often been tested against ice of greater thickness, neither is it likely to be so, for excepting in cases of emergency, or to serve a temporary purpose, it is usually left to become thicker. It is certain, however, that ice about an inch thick is more solid than that 4 or 5 inches or more in thickness, especially if changes in the temperature take place previous to its being secured. Ice of the latter thickness, however, breaks up better, so that when it is to be pounded as advised by Mr. Perkins, it is more convenient than thinner ice; but the propriety of pounding it very fine has been questioned by many, and as there are evidently objections to doing so, let us see what these really are.

In the first place, it will, I think, be admitted, that the best way to ensure the good keeping of ice, is to render the mass as dense as possible. Will anybody wonder if it does? In years gone by it was customary to break ice up in smaller pieces in order that they might measure out more. Now, if ice does this, the object is defeated; it is true, the pounded ice is intended to be rammed together again, but unless the weather be very frosty at the time, the pieces when so broken will be liable to melt and waste before the ice can be rammed again, and I am far from certain whether under any circumstances they can be made to form so dense a mass as before. I would, on the whole, prefer a portion of the ice to be broken somewhat like red metal, and some much finer, so that in the amalgamation all the cavities that would have been left in the mass, had been completely filled with rough lumps thrown together, may be the better filled by the smaller pieces. This is the mode which we generally adopt here, and I believe it is that followed at most places. It has the recommendation of convenience, and is more quickly carried out than if the whole of the ice were broken small; and as the filling of an ice-house is a work that must be performed in one or two days, it is better to complete it in the time and way specified, rather than only half do so in another manner. As the quantity has much to do with the ice-keeping long, it is better in all cases to fill the house, well, or whatever place it is stored in.

Strict ice has for many years been a subject as to which

considerable diversity of opinion has existed. Some of the early writers in London's "Gardener's Magazine," recommended water to be added to the pounded ice, as the ice-well became filled; and some went so far as to say that hot water was better than cold, and this opinion is shared by some at the present day; but I never could perceive that hot water when employed for such a purpose had any merit beyond novelty. Generally speaking, the temperature of an ice-house when the men are at work in it, is not low enough to freeze cold water quickly, and I think anything likely to increase the heat of the place must be hurtful rather than otherwise. Salt has been also applied, and at one time had many advocates, but having a great affinity for moisture it interfered with the sound keeping of the mass, and its use has been generally abandoned, although it is employed in the application of the rough ice to confectionary, &c. Indeed, all artificial additions, so far as I am aware, fail to prolong the time during which ice may be kept.

Although there may be a difference between the melting powers of a dry atmosphere and of a moist one, there can be no question that warmth causes ice to melt, and the temperature of an ice-well in summer, when its contents have disappeared, is more likely to be 35° than below it. The wasting of the ice is slow or rapid according to the temperature; though I do not assert that humidity has nothing to do with the ice liquefying, still the hygrometer is seldom introduced into the ice-house, and I am more disposed to attribute the wasting of the ice to warmth than to moisture. It is idle to talk of keeping an ice-house dry, keep it as cold as you can, and it will not suffer from damp—that is, if the thermometer can be kept low enough, but this being impossible, the next best means is to expose the ice as little as may be to the action of the air. This object is usually sought to be effected by covering the ice with straw, so as to prevent as far as possible the access of air; but any other non-conducting substance would do as well as straw. I am not sure that sawdust would not be better, but it is not so easily applied, and its removal in order to take out the ice when wanted is more inconvenient. Surrounding the ice with a non-conducting substance, so as to keep it from contact with anything warmer than itself, is almost all that can be done towards keeping it. Usually, when an ice-well is filled, the ice begins to melt or waste at the sides and top, and very possibly at the bottom also, leaving a cavity between the mass and the wall of the building; this cavity increases in size as the season advances, and towards the end all that is left is a lump of ice of greater or less size in the middle. To cover this lump with straw or sawdust is not a difficult matter: in fact, it is usually covered as soon as it has receded sufficiently far from the roof and outer walls to allow of this being done.

The difference in the keeping qualities of ice-wells is due to local causes; but most generally those wells keep ice best which are dug in dry places, and the soil surrounding the casing of the ice-well being cooled down to about 32°, it receives warmth very slowly from the almost non-conducting medium which lies next to it. When, on the other hand, water abounds in a soil it becomes a never-ceasing source of heating. An example of this occurred in an ice-house which was once pointed out to me. The well was sunk in a wet gravel; but means were adopted to drain all water away from the bottom, and it was thought by well cementing the brickwork forming the lining of the well, so as to exclude the spring water, and carrying off the latter by a drain at the bottom, all was done that was necessary. The result proved that such was not the case. The well, acting as a drain to all adjoining springs, these flowed in its direction, and as spring water is usually 15° or more, higher than melting ice, the brickwork might be said to have been warmed externally by water flowing continually towards it and trickling down its sides. To say that the ice-well was heated with hot water was not far from the truth, seeing that that water was much warmer than the substance to which it gave warmth. The result was that the ice kept very badly. Although no water found its way through the brickwork, or collected in any quantity at the bottom, yet that trickling down the outside and discharged by a proper drain, was equal to about two hundred gallons per hour.

Mr. Fish has made some useful suggestions about the formation of a box or safe for ice for household purposes; but I fear that the demand for cork for other purposes renders its use unlikely in many cases. A very good box may be made of ordinary deal, lined with zinc or zinc plates, having a cavity of about an inch between the zinc and the outer deal, to be filled with pounded charcoal. This non-conducting substance is per-

haps as good as anything that I know; but of course the close-fitting of the lid and other circumstances determine to a great extent the good-keeping or otherwise of the contents. Such an apparatus has been in use for some years; but, as Mr. Fish justly observes, it is the frequent opening of the case and disturbing the ice inside that occasion the waste, and it is difficult to prevent this, although the ingenious contrivance recommended by Mr. Fish to obtain cool water without doing so deserves notice.

As the subject of ice-stacks was discussed in this Journal some years ago, it is unnecessary to refer to that mode of preserving a supply now, and the few places in which it has succeeded, as well as the expense of covering the stacks with straw or some substance of a similar nature, renders it more expensive than storing ice away in a well or other depository of a permanent character. At the same time I am not certain but that a building more above the surface than under it may not answer as well as the latter; but these are not yet sufficiently numerous to be put in competition with the ordinary form of ice-wells, and the cases in which they do either remarkably well or the contrary may be owing to some local cause, so that it is difficult in the present state of the question to pronounce a decided opinion.—J. ROBINSON.

ROSES.

Your correspondent "P." at page 86, appears a little surprised at the character I have given King's Acre. If he will look back into Nos. 179, 185, 188, 192, and 226, he will find that I am not the only one who has formed a favourable opinion of that Rose. I had three blooms of it, one of which was particularly fine, indeed I had no other variety at the time that could bear comparison with it, except, perhaps, Gloire de Dijon and Souvenir de la Malmaison, but, then, I never had the former in greater perfection either here or anywhere else. "P." says that from one plant he had several blooms; now, may this not in a great measure account for the disappointment? I am strongly of opinion, indeed I feel convinced, that if I had allowed all the buds that made their appearance on my small plant to have expanded, I should not have had a bloom worth looking at. I never allow a plant to have more than three blooms the first season after planting, very frequently only one, and sometimes none at all, according to the size and condition of the plant. Whether this is a proper mode of treatment under all circumstances I do not presume to say, for I am but a very humble authority on Rose culture; but I certainly do think that in a season so extraordinarily hot and dry as the last it was rather too much to expect both quantity and quality, more especially if his plant is, like mine, on the briar, and if he had not a sufficiency of water, which was a general complaint throughout the country. I am fortunate enough to have a river in front of my house, within 5 yards of my garden; I consequently had an unlimited supply, which I stood much in need of.

I may here mention that I put in at the same time with King's Acre a strong plant of Prince Léon, and the blooms it produced were quite open in the centre, indeed any one not knowing the variety would have pronounced it worthless. I had also one or two others—and strong healthy-looking plants they were—that never showed a leaf until the middle of June, although they had every attention paid them. King's Acre was the worst-looking plant of the lot, at least in regard to root, for it was very bare, but it did better than any of them. I am not sure that I know exactly the cause of all this, but I think it is owing in a great measure to change of soil and situation, and to the dry season which followed. One fact, however, I beg to state—viz., that when Roses are received from a nursery, unless they are planted in soil as good as that from which they have been removed, and in situations equally favourable, they cannot be expected to establish themselves thoroughly the first season; they ought in fairness to have another year's grace allowed them before being condemned.

"P." has left us in the dark as to the locality in which his Roses are grown, but from his letter we may reasonably suppose his residence to be somewhere in the south of England; if so, I must remind him that I am in the heart of the highlands, and anything I have written on the Rose has reference solely to the properties of the varieties as regards their suitability for northern situations. I have grown Roses and seen them grown in various parts of England, both north and south—from Dorset to Durham I may say—and I com-

ment I their cultivation here with the view of finding out what varieties were best adapted to the climate; I have, therefore, recommended such only as have done well with me. What I have said of King's Acre I would have no hesitation in repeating. As regards its merits in comparison with Jules Margottin, I have to state that I was thinking of it at the time I wrote more particularly as a bolder. Jules is a fine Rose for this purpose we all know, but King's Acre, equally robust, appears to be more compact in habit, and is evidently a profuse bloomer; the colour, if I may judge from his letter, is not quite so pleasing to the eye of "P." This is merely a matter of taste; in my opinion it is equally good, and certainly a greater novelty. I have not seen Jules Margottin so fine here as in the south, but neither here nor elsewhere have I seen a bloom of it superior to the one I had of King's Acre; but time will settle the matter, next July we shall be in a better position to discuss their respective merits.

Referring to another part of "P.'s" letter, I have to inform him that Gloire de Santenay opened beautifully with me; I had only two blooms of it, as I had but a single plant, but they were very fine. This and Francis Lacharme, should their constitutions prove sufficiently strong, will, I think, be fit to rank with the six best crimson Roses for this part of the country. I would like, however, to have them another season before speaking positively in regard to them. Their flowers are quite globular when expanded.

General Washington has in one or two instances opened well here, but its buds are very apt to split, more especially the first crop. I therefore intend pruning late this season by way of experiment. Duc de Rohan and Maurice Bernardin have not as yet opened so well as I could wish, but I have not lost hope of either, more particularly the latter. I shall not feel greatly surprised to see them both in fine bloom this next season.

Prince Camille de Rohan is well worthy of the character "P." has given it, but I am beginning to fear that it is not exactly suited to this locality, which I much regret, for no dark Rose stands higher in my estimation. That it will ever attain the position he has assigned it I very much doubt; I am rather inclined to think that with King's Acre he will sooner be in possession of a flower worthy of being classed A1 than I shall with Prince Camille de Rohan.—Loch Ness.

THE CALVILLE BLANCHE APPLE.

Many years ago I used to hear, when travelling in France, the merits of this variety highly extolled by the French cooks and housewives. Like most of us English, I felt that French Apples were not to be compared to ours, and I often told them so. It was of no use; they always would persist that no Apple in the world could equal their Calville Blanche when cooked, and it is only within these few years that I have been compelled to think as they do; and I fully believe that when this sort is grown on trees well cultivated in a warm climate—not on standard trees—it is the finest of all Apples for the kitchen. In the south of England, in warm favourable soils, it may be cultivated in gardens; but it should be grafted on the English hardiest stock. In cool climates it requires either the orchard-house or a wall with a warm aspect to bring out its fine quality. At Fontham it is, or used to be, largely grown on trees in pots under glass, and warmly patronised by the French *chef*.

To enjoy its fine flavour it should be baked. There are two modes of doing this.

1st. Peel the Apples, cut them in quarters, place them in a glass jar, sprinkle a very small quantity of sugar over them, and bake them in a slow oven till done. They give out plenty of juice, and are most delicious.

2nd. Take a small piece the size of a sixpence out of the crown, fill the cavity with sugar, cut off the stalk, and place the Apple stalk downwards on a tin plate, and bake in a slow oven till quite tender. They become a perfect sweetmeat, and are as superior to the Normandy Beeings as a Pine is to an Orleans Plum.—T. R.

LARGE STANDARD CAMELLIA.—In my garden facing the north is a Double White Camellia, more than 7 feet in height, and covering 10 feet round. It is supposed to be sixty years old, or more. It is now covered with buds in clusters, and last year I gathered two nearly in full blossom. It has always been covered during the winter with matting; but we have

been advised to discontinue this, and merely to cover the roots with dead leaves, for when covered as before the roots became dry, causing the buds to drop off when bursting. It is now in perfect health and vigour, standing on a lawn, and promises well for the future.—F. ELLMAN, *Battle, Sussex*.

PLANTING VINES.

I HAVE read with satisfaction Mr. Thomson's interesting article upon the planting of Vines in your Number of January 30th, and as the subject is of considerable importance, I venture to ask if Mr. Thomson, or any other celebrated Grape-grower, has tried the following method which I noticed some years ago in the columns of a contemporary. I quote from memory.

A month or five weeks before the Vines are to be planted, a hotbed should be prepared as for Cucumbers or Melons. After the heat has sufficiently subsided, a few inches of soil should be spread over the bed, and the Vines turned out of their pots and placed upon it at a few inches apart, and the interstices filled up with suitable soil. I presume there would be no frame or covering over the Vine roots. After remaining upon the bed a fortnight or three weeks, the Vines should be carefully lifted and planted in the vinery, and watered with warm water, the border being previously warmed where practicable; and where no heat can be applied to the border, the Vines should not be planted till the beginning of May.—*INQUIRER*.

We forwarded this inquiry to Mr. Thomson, and the following is his reply:—

"The method of planting Vines, detailed by "INQUIRER," will, doubtless, answer very well where the border is heated; but as it has never been adopted by me, I cannot, therefore, recommend it from experience. I have, however, a decided objection to removing Vines from a strong bottom heat to ordinary Vine-borders, or to stimulating their roots before planting.

"The mode of planting which I have always found the most satisfactory, is to leave the Vines, presuming that they are plants raised from eyes in the previous season, in a cool airy house till they burst their buds about a quarter of an inch. They are then turned out of their pots, shaken entirely free from the soil, and well rinsed in tepid water in order to free them from all inert soil. The roots are then dredged with fine sand, and in planting every rootlet is carefully spread out, covered with a little fine soil, and then watered with water at about 80°. The vinery is kept close and moist for a time, and the heat increased as the Vines progress. They make about a foot of growth from each bud rapidly, and then stand still for a little time till the roots come into action. I do not believe that it is natural for the Vine to make fresh roots till it has expanded foliage. I have at present some Vines in the pots in which they were grown last year, and they have no signs of fresh roots, while the tops are 8 inches long; and this I have noticed for years in succession.

"Sometimes I have cut the Vines down, allowed them to grow a foot or so, and then shaken them out and planted them, and in this way they go on nicely. I have tried several other ways, but these are the two I prefer.

"Perhaps the finest canes I have seen produced in a season's growth were struck from eyes early in spring, and planted in May; and with bottom heat, or even when the Vines can be planted inside, I would as soon adopt this practice as any that I know. I have planted spring-struck plants in June in outside borders, placed a hand-glass over the roots and kept it close for a time, and the Vines never retrograded in the least.

"In connection with young Vines, I may refer to an instance of Vines that I wanted to grow in 1865, for planting in pots this year. These, after they had grown about 18 inches, were potted into 16-inch pots and placed in a Muscat-house where the buds had just broken. Under unfortunate circumstances they were allowed to remain in the Muscat-house till the Vines closed over them, and so shaded them that in the high temperature they grew till they completely lost their growing energy, and were so drawn and weakly that at first sight I determined to throw them out. However, they were moved to another house where there was plenty of light, and were ent down to within an eye or two of the surface of the soil in the pot; they soon pushed the top bud of that same season's growth and grew away with amazing vigour. The result was, that I never saw such pot Vines before. They are from 9 to 10 feet long, and as thick as a man's finger.

"I am convinced that this cutting-down system of the same season's growth is a good one, and I mean to adopt it. The main bud that in ordinary circumstances would not burst till next year, must be made to push by removing all the laterals.—D. THOMSON."]

LUCUMA DELICIOSA.

In your Number for December 26th your correspondent "RADDIT" asks if *Lucuma deliciosa* has fruited in this country, to which you say "There is no species known to botanists, we think, as *Lucuma deliciosa*. Our correspondent probably refers to *L. mammosa*, or Teated Mammee Sapota, &c." In walking through the gardens of James Bateman, Esq., at Knypersley, the other day, I saw in the old tropical fruit-house a plant about 5 feet high of *Lucuma deliciosa*. It is a native, I believe, of Peru, and was sent to Mr. Bateman from the continent. Mr. Bateman has just fitted up a large house for the growth of tropical fruits on the principle of "J. H.," and of which you will hear more anon.—Q. READ.

[We find no species so named in any botanical work.—EDS.]

NOTES ON CYCLAMENS.

ALL admirers of the Cyclamen tribe must feel much obliged to Mr. Wanklyn ("W. X. W."), for his interesting notes on Cyclamens, and their native habitats, &c., page 378 of the last, and page 23 of the present volume of THE JOURNAL OF HORTICULTURE. With respect to the species found by Mr. Wanklyn in the spring in Sicily, I have great doubts of its being *hederaefolium* (*neapolitanum* of Tenore), as that is essentially an autumn bloomer, and the flowers for the most part rise before the leaves make their appearance. I have very little doubt but it would prove to be *Cyclamen repandum* of "Flora Græca," and some other authorities, which is by no means confined to Greece, but is widely distributed over the south of Europe, Turkey, and probably Syria. I can speak to its being almost, if not quite as frequently met with as *hederaefolium* (*neapolitanum*) in middle and southern Italy, and they are often found growing together in the same locality. Its so rapidly coming into bloom, as Mr. Wanklyn notices, and also the period of the year, quite correspond with the habits of *C. repandum*. The flowers vary in the shade of colour; it does not generally rise to the surface of the soil, out of doors much before March; its growth is then very rapid, and it is quickly in bloom. *Hederaefolium* (*neapolitanum*) would by that time be rapidly going to rest. The large tuber observed by Mr. Wanklyn, at Solomon's Pool, near Jerusalem, would probably be *C. persicum*, that being a native of Palestine. I have some now in cultivation the tubers of which were brought direct from thence. Being at all times much interested in learning any facts relative to the habitats of any of the Cyclamen tribe, and not fond of guess work on subjects of this sort (of which the poor Cyclamen family have long had abundance), I would, provided Mr. Wanklyn will not consider me troublesome, and will kindly favour me with his address, either privately or through the Editors of this Journal, endeavour to clear up this point by sending him some flowers and leaves of the true Italian *C. repandum* when it is in bloom, probably about April or May.

Without entering on the general subject embraced in Mr. Abbey's papers on this family, I would just remark that he is rather hasty in stating (page 523), "there being no good white form of *C. europæum*." He may not have met with one, but I can testify to the reverse, having repeatedly, though rarely I admit, found good pure white ones amongst the Alps of Switzerland and Savoy, and still grow them. I certainly had not *C. europæum album* in view when I spoke of *C. odoratum* being with some identical with *C. europæum*, but rather the southern variety of that species recently figured as *C. europæum Peakeanum*, which, as your correspondent "S." (page 501) suggests, is certainly only the variety of *C. europæum* found in several localities "on the Italian slopes of the Alps." Its habits are precisely what he describes. Under shelter and with moderate warmth it is evergreen, and almost constantly in bloom, but under natural treatment has its period of rest the same as most other plants, and is benefited thereby. I have grown it ever since about 1843, and some years since I brought home a considerable quantity from its native habitats. During the many years I have been a collector of Cyclamens, I have received it under the names of *odoratum*, *fragrans*, *Clusii*,

æstivum, *littorale*, and some others. It is, therefore, by no means new, though a very desirable variety, and well worthy of more extensive cultivation than it, as well as some other varieties of *C. europæum*, have hitherto received. A tuber I have on rockwork in a hardy Fern-house, commenced blooming early last June, and continued until the end of January. Being without artificial warmth it will probably before a great while go to rest.—J. ATKINS, *Painswick*.

INCISIONS IN VINE ROOTS.

I OBSERVE that "A CONSTANT READER," in the Journal of February 6th, asks if his Vine, whose roots he has nicked as I did those at Wrotham Park, will bleed to death. The eases are, however, not parallel, for those that I nicked were cut off from supplies of sap, torn as they were out of the ground altogether. In his case I think it extremely probable that they will bleed, but not so as to cause the death of his Vine. In common with every one who has taken up a tree the roots of which had previously been cut-in, and fresh soil put to them, I observed that they made fine tufts of new roots; and to make the long bare Vine roots that I had raised out of the old effete soil do this along their whole length, as well as at their very extremities, I cut the notches in question, which were about a quarter through the root, and on alternate sides throughout the length of the roots. The effect was just what I have stated in the work he refers to.

Your correspondent need be under no apprehension that his Vine will die. If it bleeds severely, its doing so may retard the bursting of the buds, and the growth for a time may be weaker than usual; but if he lay fresh soil round the wounds, into this, during the summer, the upper lips of the incisions will most certainly send young roots, and the Vine instead of being killed will ultimately be benefited.—Wm. THOMSON.

THE COIL SYSTEM OF PLANTING GRAPE VINES.

I AM aware that no one should think lightly of anything from the pens of two such horticulturists as Mr. Rivers and Mr. Thomson; but having had a fair share of experience during the last fifteen years in Vine planting, I must say that I have great objections to the layering system.

In the spring of 1850 I assisted in planting a new vinery; but not an inch more of the stem was covered than could be avoided, and the Vines have done well from that time to this. Again in 1855, at another place, I assisted in making Vine-borders and planting them, also in layering some Muscat and Royal Muscadine Vines, which never grew satisfactorily, and which, at the end of two years, were taken out and planted again, while the Vines not layered did remarkably well, and were the admiration of some of our most successful Grape-growers.

In my next situation I had the care of some very fine vineries, which had been the means of causing some hot discussions twice or thrice in ten years; but the gardener leaving soon afterwards, his successor obtained permission to take up the Vines in what had been the early-house. They were taken up as carefully as possible, for it was intended to replant some of them, and the border was re-made on what was by some considered the best plan, and there was a chamber underneath, heated by four four-inch pipes. By the way, this plan I never could approve of, and ventured to say so at the time. Well, seven of the old Vines were replanted, the rods being layered in the border and covered for 6 or 8 feet; the rest were young Vines, obtained from Mr. Rivers's nursery, and were also layered. The house being set to work, the young Vines did better than the old; but not one reached the top of the house, and the canes were very little thicker than a writing pen. The old Vines had a hard struggle for existence, and did not grow more than 3 feet; in the following spring they started somewhat better. Having obtained another situation, I left; but feeling very much interested in these Vines, I made in the autumn a long journey to see them, and found them in a sorry plight. I then remarked to the man who had been with me, that the Vines would not be long before they would have to be removed, and so it proved; for after another year's trial they were taken out and the house replanted, but not on the layering system. I understand they are now satisfactory.

I have had four vineries built here and planted, and if it

would be of any interest to the readers of *THE JOURNAL OF HORTICULTURE*, I would give a plan of the range, as the border is above the level of the surrounding ground. So far I must agree with Mr. Thomson; but with respect to trees I have not seen the evil consequences of burying the stems, on the contrary, it has had a very beneficial effect. As an instance, I may state that there is an avenue at this place, planted about ten years ago, and some alterations being afterwards made, the stems of some of the trees were covered to the height of 1 foot, and now the trees are by far the best, so much so, that the owners had several trees banked-up, and in every case with success. Mr. May, of the Hope Nursery, Bedale, Yorkshire, also gave two or three years ago an account of some Apple trees so covered, and of the good effects which resulted; not that I would advise such a plan with fruit trees; but I think that it would be beneficial to forest trees in some soils and situations. There are few rules, however, without exceptions.—T. T.

ROYAL HORTICULTURAL SOCIETY.

ANNUAL GENERAL MEETING.

Tins was held on Tuesday the 13th inst., the Duke of Buccleuch President, being in the chair. The minutes of the last annual meeting having been read and confirmed, Mr. Fontaine and Mr. Booth were nominated scrutineers of the ballot, which was proceeded with whilst the report of the Council was being read by Mr. W. Wilson Saunders, the Secretary.

The report states that the number of Fellows increases, and the subscription still more; regrets the deaths which have occurred; states that the exhibitions were successful; that the income of the Society has increased and its expenditure decreased. The admissions were—1863, 115,521; 1864, 185,692; 1865, 231,519. The Fruit and Floral Meetings have been successful and popular; the produce of Chiswick not so successful as expected, owing to the failure of the Strawberry crop and other causes. The number of packets of cuttings received by members has been 1539, of plants 6265, of packets of flower and vegetable seeds 376,881. The appointment of the Rev. M. J. Berkeley as botanical adviser is then referred to; also that he, Dr. Hogg, and Mr. Moore are to supervise the operations and conduct the experiments at Chiswick, the latter two gentlemen also examining candidates for the Society's certificates; and the report concludes with notices of the intended proceedings of the current year.

The result of the ballot was then reported to be that the Duke of Buccleuch was elected President; G. F. Wilson, Esq., F.R.S., Treasurer; and Lieut. Col. Scott, R.E., Secretary, for the ensuing year; and that Viscount Sandon, the Right Hon. W. Cowper, M.P., and Sigismund Richter, Esq., were elected new members of Council in the room of J. J. Blandy, Esq., John Kella, Esq., M.P., and Major Trevor Clarke, the three members retiring according to the charter. G. F. Wilson, Esq., Lieut.-Col. Scott, and Henry Cole, Esq., C.B., were elected Expenses Committee; and J. Nicholson, Jonathan Clarke, and R. Hudson, Esqrs., Auditors.

Sir A. SCOTT WATSON, in moving the adoption of the report, said that it had given him the greatest satisfaction. An institution like the Society ought to be progressive in its nature, and he was much pleased at the improvements which had been effected in the gardens, as well as at the extension of the privileges of the members. These, he felt sure, would occur in the regret expressed in the report at the loss in one year of three men so eminent in the horticultural world as Dr. Lindley, Sir Joseph Paxton, and Sir William Hooker. He observed with satisfaction paragraph 16 of the report, in which the Council stated their intention to carry out experiments, which would no doubt serve to advance the science of horticulture.

Major BURNERS, in seconding the motion, expressed his entire satisfaction at the prosperity of the Society.

Mr. N. VILLIERS GUNSVILL did not quite understand paragraph 20 of the report, having reference to the admission of the Fellows of the Society to the International Exhibition of May next. Was he to understand that they ever would be an exhibition in the grounds from which the Fellows would be excluded?

Mr. H. COLE said that the main part of the exhibition would not be held in the Society's gardens, but on the ground on which the Exhibition of 1862 stood; but still, if it were to be held in the Society's grounds, the Fellows would enjoy greater advantages than if no such exhibition were to be held at all. Of course, the promoters of this great national exhibition knew that it had to be paid for, and they had to look to a way of meeting their adventure. They said, "We shall be laid off all the accommodation which the Society can give us, and for that we will give you £3000, and, further, we will give the Fellows the first public entry to this great exhibition." That took place on the second day; on the first the admission was limited to those who had subscribed and guaranteed the money to pay for the exhibition, which would be on an enormous scale. Thus the Society, besides adding £300 to its funds, secured for its Fellows a free admission to a great public exhibition; and he trusted that the Fellows were satisfied that the Council had done what was best for their interests.

Mr. GREYVILL expressed his satisfaction at Mr. Cole's explanation,

but hoped that the course adopted would not be construed into a precedent for holding exhibitions by which the Fellows might be at any time debarred from going into their own grounds.

The CHAIRMAN explained that the Fellows were not debarred from going into the gardens, but would have at all times free access to all parts of the exhibition within their own grounds, except when the plants and fruits were being arranged and judged.

The motion for the adoption of the report having been put to the meeting and unanimously agreed to, a letter was read in which Messrs. Lee & Parker reported the valuation of the Society's stock at Kensington to be £3783 11s. 6d., and at Chiswick, £2202 17s. 6d. or £5986 6s. 6d. in all.

A FELLOW asked the Council to reconsider their decision as to the admission of the public at 3s. on five days a week during the autumnal months, and inquired whether the experiment had proved successful.

Another FELLOW asked how many persons had availed themselves of the privilege, and whether there were any countervailing disadvantages.

Lord H. GORDON LENNOX, M.P., answered that the result had been a great financial success; and so far from any damage having been done to the gardens, he was happy to say that there was none whatever.

Mr. COLE remarked that the cheap admissions only took place in August and September, when London might be said to be out of town.

Colonel CHALLONER observed that as a very old member he thought the threepenny admission lowered the character of the Society, and he knew many ladies felt dissatisfied after having paid their £40, or four guineas per annum, at the gardens being thrown open at such a charge. They would rather that certain days should be free.

Mr. EDGAR BOWRING wished to say a few words on the threepenny admissions from a Commissioner's point of view. The Commissioners gave up the land to the Society that was the produce, in 1851, of the shillings of the million, and the Commissioners felt that it was property held by them in trust for the public. He might observe that the Society had acquired twenty-two acres of land without any payment in what was now becoming a densely-peopled neighbourhood, and which was worth from one-quarter to one-half a million sterling. In addition, the Commissioners had spent between £60,000 and £70,000, themselves, and the total rent paid last year was £185, and the Fellows would recollect that in the previous year no rent was paid at all, so that it was quite clear that the Society held this large estate for nothing. It was then a question whether the general public should not have some privilege in respect of these gardens. He did not know what was the best shape that privilege should take, but he agreed with Colonel Challoner that the better plan would be to throw open the gardens at certain times free.

Sir A. WAREH considered that the gardens were not to be looked upon as being wholly for the selfish enjoyment of the Fellows and their friends, but should be regarded in a scientific point of view for the benefit of the public.

Lord H. LENNOX said the subject had been under the consideration of the Council, and they felt that the gardens might be made available for the use of artisans when the Fellows, for the most part, were out of town. The Council were anxious to hear whether they had better continue the present system of threepenny admissions, or whether the gardens should be open in the autumn on Mondays. The latter course, he assured the meeting, might be adopted with perfect confidence that there would be no damage done.

The CHAIRMAN said that it was the object of the Council to elicit from the meeting whether the public should be admitted free on one day, or on five days at the charge of 3d.

On this subject some discussion then took place, in which Colonel Challoner, Lord H. Lennox, Mr. Cole, Mr. Penny, and Mr. Sidney Smith took part, and a motion was made to admit the public free on Mondays during the months of August and September; but it was withdrawn, and ultimately it was resolved that the subject should be left to be dealt with by the Council.

Dr. RICHARDSON then put some questions relative to the privileges of two-guinea Fellows, complained that these privileges were not made sufficiently intelligible, and, finally, that whereas four-guinea members had forty admission orders and two transferable tickets, the two-guinea members had only twenty such orders and one non-transferable ticket. Therefore, he argued that the two-guinea members had not half the privileges of those paying the higher rate of subscription.

Mr. COLE said that Dr. Richardson appeared to think that the two-guinea members should have *all* the privileges of the four-guinea ones. He himself would like to make two-guinea do the work of four as well as any one; but it was necessary that there should be some inducement held out for members to pay the higher rate of subscription, and that had not been done by taking away any privileges from the two-guinea subscribers.

Dr. RICHARDSON repudiated any idea of wishing the two-guinea subscribers to usurp the privileges of those paying four; all he wanted was that members' privileges should in each case be distinctly understood.

Mr. SYDNEY SMITH thought there ought to be a series of lectures on botany and horticulture in addition to the Tuesday meetings, than which nothing, however, could be more delightful; and he imagined this could be done without much, if any, additional expense, as there were plenty of gentlemen who would give lectures free.

The CHAIRMAN assured the meeting that if the Council found any-

thing obscure in the summary of the privileges of the Fellows it should be made plain; and then, in virtue of his office as President, nominated Earl Grosvenor, M.P., Lord H. Lennox, M.P., W. W. Saunders, Esq., and J. Bateman, Esq., Vice-Presidents for the ensuing year.

A vote of thanks was then unanimously passed, on the motion of Mr. Bowring, to his Grace the Chairman and the rest of the Council.

At the Meeting on Saturday, the 17th inst., there was a much larger display of flowers, fruits, and vegetables than has been exhibited on any former occasion. It is quite evident that these meetings are acquiring a large amount of favour, and go on improving as the season advances.

Messrs. Cutbush & Son, of Highgate, had a beautiful show of forced flowers, consisting of the *Convallaria* exhibited last week, interspersed with *Magnolia Soulangiana*, *Berberis japonica*, *Azalea*, *Rhododendrons*, *Dielytra*, *Prunus sinensis*, &c. This received the first prize.

Mr. E. Robinson, gardener to R. Benyon, Esq., Reading, sent a very meritorious exhibition, consisting of eleven beautifully-grown plants in pots of *Otaheite Oranges*, laden with fruit. Although the largest of them was not 18 inches high, some of the plants bore as many as fourteen large full-sized Oranges, and the whole formed a very ornamental group. We cannot conceive anything better adapted to the ornament of the dinner table than such plants as these of Mr. Robinson's—110 fruit in all. All honour to Mr. Robinson. An extra first prize was awarded to them.

Mrs. B. Hoake, Munster Road, Fulham, sent four pots of well-grown *Cyclamens*—a mass of bloom, and very well grown, and to which a first-class certificate was awarded.

Mr. Bartlett, of Hammersmith, again exhibited forced bulbs, to which a first-class certificate was awarded.

Messrs. Cutbush & Son sent a collection of forced *Hyacinths*, *Tulips*, and *Polyanthus Narcissus*, to which a second prize was awarded. They also exhibited a beautiful collection of twelve *Hyacinths*, which received a third prize; and a collection of *Crocus*, which was awarded a first-class certificate.

Mr. Young, gardener to Mrs. Barclay, Highgate, sent a collection of five *Dracenas*—*Cooperi*, *ferrea variegata*, *terminalis*, *marginata*, and *ferrea*, which received a first-class certificate.

Mr. Earley, gardener to Felix Pryor, Esq., sent a pot of the lovely little *Scilla bifolia*, and a good specimen in balloon shape of *Franciscea eximia*, which received a first-class certificate. He also exhibited an excellent collection of vegetables, which received the first prize.

Mr. H. Beasley, gardener to Mr. T. Wood, Twyford Abbey, Acton, received a second prize for a smaller collection; and Mr. Earley received a third prize for six dishes of Apples.

Messrs. Lucking received a first-class certificate for forced flowers.

TABLE DECORATIVE PLANTS.

As table plants are now, like *crinoline*, among the accepted by Fashion, though, unlike *crinoline*, they are ornamental and not inconvenient, it may not be out of place to say a few words in this Journal about some which experience has taught to be among the best.

FERNS come foremost. When I say Ferns, I allude to moderately large plants of the gold and silver varieties. For instance, nothing can present a more beautiful or graceful appearance on the dinner-table than a plant or plants of the *Gymnogramma peruviana* or *G. Wetenhalliana*, and amongst the golden varieties *Gymnogramma Laucheana*, *G. sulphurea*, and *G. chrysophylla*. I have seen these used extensively on the table of that great lover of horticulture, J. L. Naper, Esq., of Lougherow, and as they are grown by Mr. Burns, Mr. Naper's gardener (who, by-the-by, is quite an enthusiast in growing Ferns), nothing can present a more rich and graceful appearance.

I have also seen Mr. Burns use *Marantas vittata*, *ornata*, *regalis*, *albo-lineata*, *zebrina*, and *Warszewiczii*, with very successful effect.

He also uses different varieties of *Dracena* with good effect on the side table—*Dracenas reflexa*, *ferrea*, *stricta*, and *terminalis*.

For the breakfast-table, in shallow low vases, *Eriocnema marmorea*, *Eranthemum rubrovenum*, and several others, which at some future time I may mention, have a good effect.—R. M.

(To be continued.)

BOTANY OF MIDDLESEX.—Dr. Henry Trimen and Mr. W. Thistelton Dyer are collecting materials for a Flora of the county of Middlesex, on the plan of the Cambridgeshire and Essex Floras. They will feel indebted to botanists who will

send them local lists, notes of localities, or any information connected with the subject; in the case of rare, critical, or doubtful species, the loan of specimens will be very acceptable. Dr. Trimen's address is 71, Guildford Street, Russell Square, London, W.C.; Mr. Thistelton Dyer's, Christ Church, Oxford.

HANUM FRUIT.

I HOPE that in the course of the summer we shall learn the botanical name of the fruit of which Mr. Wanklyn has given us (page 126) so interesting a description. If it were not premature and idle to give a guess, I should think it likely to be *Cucumis dudaim*, called also *Cucumis odoratissimus*, first cultivated in England A.D. 1705.—G. S.

[We think you are right in your surmise. Mr. Wanklyn's further description of the plant in a private letter very closely agrees with the description in Dillenius's "*Hortus Elthamensis*." Mr. Wanklyn also sent us a leaf which agrees with the engraving in Dillenius.]

OAK IN THE COAL FORMATION.

KNOWING the interest you and the readers of your valuable paper take in all sorts of natural curiosities, &c., I am led to send you a very brief account of a log of Oak taken out of a seam of smut or coal on Gresley Common, Derbyshire. The log is about 6 feet long and 18 inches in diameter, partially decayed through the middle, but otherwise perfectly sound, and the grain very beautiful, capable of taking a high polish, and very black in colour. A gentleman in the neighbourhood, who has for many years studied geology, and is considered an authority on such subjects, has seen it, also the place from whence dug. I quote some paragraphs from his letter, as giving a better description than I could. He says, "The fact is a very interesting one, much more so, indeed, than I expected to have found it." "The tree must, indeed, be one of the most ancient of Oaks, for it could only have reached the situation in which it was found by being floated in the water or frozen in the ice, by one of which agencies the clay drift was deposited. This puts back the date to that of the existence of the mammoth and other extinct animals," &c. "I should put your Oak back to a date long anterior to the deposit of the so-called bog Oak, found in low-lying swamps." "The discovery of the tree will, most probably, form the subject of a paper at the next meeting of the Midland Scientific Association," held on the 27th inst.

I shall be most happy to show the tree to any of the readers of "our Journal" who may think it worth a journey to the Pool Works, Gresley Common, near Burton-on-Trent.—HENRY D. EXSON.

PARADISE AND QUINCE STOCKS.

I SEE at page 124 of the Journal for February 13th a Mr. Pearson has been somewhat "astonished" at my recommending people to plant Apple trees on paradise stocks—*i. e.*, "*Pomme Paradis*." He goes on to tell us that he was "struck" with the pretty little trees he saw growing near Paris, and he ordered several thousands of the stock with which to astonish the people of Notts; but the "severe winter" killed more than half, and he burned the other half, or the summer did so for him—sad extremes of heat and cold they must have in his ilk.

I ask you, as coinciding judges, if you or he know anything about the severity of a Parisian winter as compared with one in Notts? I have known winters at Paris destroy trees of large diameter; and Laurels, *Laurustinus*, &c., are, or were when I was in Paris, rather sparse, as well as many other things that thrive in our blessed isle. I never saw a *Pomme Paradis* hurt by frost, and I ask French nurserymen, M. Leroy of Angers for example, whether they consider the said offending stock tender? I would also ask the nurserymen of Scotland what they have to say about it?—Messrs. Imrie, of Ayr; Messrs. Dickson & Turnbull, of Brechin, and others north of the Tay, who use the stock in question, I believe, largely.

I can say myself that in 1860-1861, I lost thousands of trees by frost, amongst them more than five hundred Kingston Black Apple; and, *apropos*, this is a physiological question as regards canker, not yet taken proper account of, but of this another time. Although I lost so many other kinds of Apples and Pears by frost, I do not think that one of my paradise

stocks was hurt, nor did the aphid and other insects follow. No maly bug will live upon Apple trees in my nurseries, although I often receive them from other places. After the new comers have been planted a few months here the bug disappears; this is another physiological fact worth considering. Mr. Pearson is not so happily circumstanced, his soil favours aphid and kills paradise stocks.

Now, as to my recommending Pears on quince stocks to be planted over the junction of the graft and stock, I have not yet found that this is bad advice. With me no Pear has yet struck its own roots into the soil from above the junction, and I have upwards of six hundred sorts on quince stocks. My soil may not be more favourable to this than to the aphid, although one of the best soils in the country for rooting generally.

I also ask the Editors what proofs they have to justify their "We think you are right." Let us have the truth without fear or ambiguity.—*JOHN SCOTT, Moriot.*

The question Mr. Pearson asked was relative to a scion on a quince stock cutting roots if the point of union be beneath the surface of the soil. We think, or rather should have said that we *know*, that it does so. Mr. Scott's soil must be very peculiar if roots are never omitted from the scion under such treatment. We have expressed no opinion about the paradise stocks.—*EDS.*

STRAWBERRIES.

REMARKS ON THE CHOICE OF VARIETIES AND THEIR CULTIVATION.

THE Strawberry is one of our oldest British fruits, having been in cultivation in this country for more than four hundred years. In a poem of the fifteenth century, by John Lidgate, called "London Lyekpeny," we find the following effusion:—

"Then unto London I dyde me hye,
Of all the land it bearyeth the pryse:
'Gode pesonell,' one began to cry—
'Strabery ryse, and Cherrys in the ryse.'"

Although the Strawberry has been so long in cultivation, I suppose that it has made greater progress towards perfection in the last quarter of a century than during any other period of its history. Having given a considerable amount of attention to the cultivation of the Strawberry, I may be excused for venturing to narrate my experience after so many valuable papers have been written on the subject; but I consider a very important feature of THE JOURNAL OF HORTICULTURE is, that discussion and intercommunication are invited on all matters of interest to its readers.

It is now a little more than two years since I gave a detailed account of the way in which I successfully cultivated the Strawberry; but since then, having experimented with a number of varieties, and adopted different modes of cultivation, I have added a little more to my stock of Strawberry lore. Two years ago this winter I prepared a piece of ground for the purpose of growing some rather new sorts, as well as some older varieties of high repute, and testing their qualities. The ground was prepared by trenching about 2 feet deep, and putting plenty of manure at the bottom of the trench. As we did not intend planting before the following autumn, it lay rough and exposed to the action of the frost until spring, when it was planted with a crop of Early Handsworth Potatoes. These were off by the early part of July; and after the ground had been nicely dug and received another dressing of dung, it was in good condition for the Strawberry plants. These were carefully propagated during the summer, the first runners that could be obtained being pegged down in 48-sized pots filled with rich compost, and as soon as they were established they were severed from the parent plants and placed in their fruiting positions. I consider it most essential to success to have the plants established early, and with all due deference to the opinions of others, I would recommend autumn planting. During the last season, having had a good quantity of plants to prepare, I propagated one half by pegging down in pots, and the other half by pegging down in the beds; and after an impartial investigation of both systems, I feel rather inclined to prefer the latter, especially when plants intended to propagate from can be grown by themselves.

Some of the varieties grown in my experimental-bed did very well, others only moderately, and others, again, refused to throw up even a single scape. Prince of Wales refused to bloom, and, therefore, suffered excommunication. I anticipated testing the reported good qualities of La Constante, but

it did not produce a single truss of bloom; this I shall try one season more, and if with no better success I will throw it away. Prince Arthur produced a quantity of very small berries, but the flavour was exquisite. Sir Charles Napier fruited at the rate of one plant out of ten, and these not very satisfactorily. The much-praised Frogmore Late Pine has not yet gratified my palate with its luscious fruit. The plants were sickly and bloomed very sparingly, and what few fruits there were never came to perfection. The whole of the above, with the exception of La Constante and the Frogmore Late Pine, have been thrown away as being of no service. To these two I intend to give another year's trial, and if they do not succeed any better they must be rejected as worthless in this soil and situation. At Biddulph Grange, not half a mile from here, La Constante last summer did well, and was one of the best. Rivers's Eliza, Carolina Superba, Marguerite, and San-pareil, did but very moderately. These remain on trial one year longer. Empress Eugénie and Eclipse in the same plantation did well. The latter is the best and most prolific variety which I have seen; the fruit from the first pickings measured 6 inches in circumference. The fruit from Empress Eugénie is large and handsome and of medium flavour, but with us this variety is not such a heavy cropper as Eclipse; the fruit is fully as large. Keens' Seedling, which has always been a favourite, has failed for the last two years. Dependance was always placed on it for the general crop, but it appeared worn out and has given place to better sorts. Our other four or five old varieties of sterling worth I dare not at present destroy. Black Prince is depended on for the general crop, but if Eclipse maintain its character, I purpose planting it largely next season. The Elton is still the best we have for a late crop in this neighbourhood, it continues in bearing until the second week in August; and Black Prince came in last summer by the 26th of June, thus prolonging the Strawberry season seven weeks. British Queen and Goliath did ample service, and well repaid the trouble in their careful cultivation. Fruit of Goliath measured between 8 and 9 inches in circumference.

The varieties which I have had the opportunity of testing, and which I find the most useful, are the Black Prince, Eclipse, Empress Eugénie, British Queen, Goliath, and Elton. I consider that half a dozen good sorts to be depended on are ample for places of moderate extent, and numerous varieties only tend to cause confusion and disappointment.

I will now offer a few remarks on the successful culture of the Strawberry. It is essentially necessary that the ground should be deeply trenched, and that plenty of dung should be placed at the bottom of the trench. The time preferred for this operation, when it can be made convenient, is winter. Sometimes it is desirable to replant immediately a piece of ground which has been previously occupied by Strawberries. When this is the case it is requisite to work in, during the process of trenching, a quantity of fresh soil. In trenching the ground of an old plantation last summer, it was found that the roots had penetrated to the depth of nearly 3 feet; hence, the importance of deeply stirring the ground and placing the manure at a good depth. The roots will naturally ramble away in search of food and moisture, and properly preparing the ground and affording a liberal supply of dung constitute the best safeguards against the ill effects of dry weather.

For mulching, or for keeping the fruit from being splashed with dirt, I have generally used straw or short grass; the latter I object to on account of its tendency to cause mouldiness and decay among the berries. Last summer I used clean fresh litter with a portion of the droppings shaken out. As soon as the bloom began to expand I cleared the plants of all runners not required for propagation, and the beds of weeds; a good thickness of litter was then carefully laid down all over the beds. This being done, and a good soaking of water (not a mere dribble), being given twice a week, notwithstanding the tropical summer which we experienced, and the long-continued drought, I never saw Strawberries look better, and never witnessed heavier crops. I know that some ladies are rather fastidious about Strawberries lying on litter, and object to its use in consequence of its imparting a disagreeable flavour to the fruit; but in order to obviate this difficulty I had short sticks prepared and placed round the plants soon after the fruit had set, and two or three pieces of matting tied round each plant according to the length of the different scapes. This system may appear to entail a little extra trouble, and so it does, but the advantages secured are more than a compensation. I do not remember having seen it practised before,

nor even reading of it until Mr. Will's told us last August, in the pages of this Journal, how he successfully adopted the same plan at Oulton. A bed of the British Queen, or any of the large varieties, when tied up and approaching maturity presents a very charming appearance.

I need not enlarge on the treatment of the plants after the fruit has been gathered. Much has been said on this subject lately, and I would recommend all who are ambitious to excel in Strawberry culture to consult those articles. I will, however, add, that I do not allow useless runners to remain on the plants, and I consider it essential to keep the beds clean and free from weeds, as every sprig of grass or intruding weed is so much abstracted from the soil, and, consequently, from the food of the future crop. Further, I still adhere to my old practice of not destroying the foliage. I will not dispute that Strawberries may be grown where the dangerous system of cutting off the leaves is practised, but I have tried both ways and consider it the better policy to allow the leaves to remain.

Strawberries can only be had in perfection when they are gathered dry, for a very little rain will destroy their flavour. Being in its natural habitat a rock plant, those soils containing the greatest amount of rock in a decomposed state, or the most clay, have been found to produce the fruit of the finest flavour.—QUINTIN READ, *Biddulph*.

STRIKING ROSE CUTTINGS.

RAISING Roses on their own roots has been so often treated of in your Journal of late, that I have been surprised at never having there met with a plan suggested by Mr. Fish many years ago, in your "first series," and which I tried at the time, and sometimes lately, with much success. I mean inserting in April or May the soft stubby shoots of that spring, while from 1½ to 3 inches long. These when treated as there desired (a slight hotbed, glass cap, and shade), became strong and vigorous plants, which gave a few flowers that same autumn, and formed strong plants from 18 inches to 2 feet high, which bloomed well in the following June, and far surpassed any other cuttings of the same age. Indeed, I have usually found that cuttings require a long time before making vigorous trees. One peculiarity is, that Roses raised in the manner I have described generally send up two or three stems, which makes them desirable for pegging down.—AGNES.

[We have never tried the plan fairly without being successful. The chief secrets of success are a rather low temperature before the cuttings begin to callus, and more heat afterwards.]

NOTES ON THE SPECIES OF HELLEBORUS.

THE Hellebores are all robust hardy perennials, and comprise among them some of the gayest spring-flowering plants which we at present possess; for no set of hardy perennials are so attractive as the Hellebores in the earlier months of the year, they producing their flowers with impunity at that season when few others can brave the inclemency of the weather. The genus *Helleborus* belongs to the same natural order (*Ranunculaceæ*) as the Larkspur, Columbine, Monkshood, Marsh Marigold, Love-in-a-Mist, and the Winter Aconite. Its name *Helleborus* is derived, according to some writers, from "hellen," to cause death, and "bora," food, on account of its poisonous qualities; but, according to Bergeret, it is derived from the river Eleborus, the Black Hellebore being found plentifully along its banks.

All the Hellebores grow freely in a rather moist and somewhat shady situation, and in a soil with which a little peat earth has been mixed.

In the cultivation of the different species of Hellebore, the principal error appears to consist in paying them too much attention, for they succeed to admiration in a retentive soil, rather shady and moist, and where they are allowed to remain undisturbed and unacquainted with the gardener's rake and hoe, for it is sufficient that the soil about them be kept clear of such weeds as grow taller than the plants themselves, and that they be completely free from the drip from trees.

The Hellebores are all easily increased by dividing the old plants when in a dormant state; or by seeds, which should be sown directly they are ripe.

HELLEBORUS ORIENTALIS, *Lamarck* (The true Black Hellebore).—*Syn. H. officinalis*, *Salisbury*; *H. olympicus ruber*, *of gardens*. This is the Black Hellebore of the ancients, formerly so cele-

brated as a medicine in mania, epilepsy, and dropsy. It is still kept for medicinal purposes in the shops of the East, where it is called "Zoptème" by the Turks. The radical leaves of the oriental Hellebore are on long stalks, pedate, somewhat pubescent on the under surface when young, and regularly serrated on the margins; while those of the floral leaves are without footstalks, palmate, and finely toothed. The flower-stems grow about a foot high, with peduncles usually forked, and bearing large solitary flowers having the sepals more or less pointed, permanent, and when young white stained with purple towards the edges, but quite green when old. It flowers from February to April.

It is the opinion of botanists that in reality the Black Hellebore of the ancients was not the *Helleborus niger*, but another species, called by some writers, *H. orientalis*, and, by others, *H. officinalis*. Dr. Lindley says, "A poison so deadly as that which the ancients called Black Hellebore would naturally attract the attention of the moderns; and accordingly from a very early period a plant occurring plentifully in the middle of Europe, and as far south as the Athos mountains in Greece, has been selected as the classical species."

The oriental Hellebore is found plentifully on mountains in most parts of the Levant, on the Bithynian Olympus, about Thessalonica, and near Constantinople. The roots are an acrid and violent purgative.

HELLEBORUS NIGER, *Linnaeus* (The Christmas Rose).—This kind is a native of woody mountains in many parts of Europe, especially those of Austria, Piedmont, Styria, Greece, Provence, the Pyrenees, and Apennines, and is an old inhabitant of English gardens, for it was introduced so far back as the year 1596.

The Christmas Rose grows from 9 to 12 inches high, and has rather large, smooth, pedate leaves, somewhat resembling a large bird's foot, and produced in the spring after the flowers are faded. The flowers are large, cup-shaped, with a white or rose-coloured corolla-like calyx, and produced in scapes from the end of December to March; at first pure white, afterwards rather pink, and finally they become green before fading.

In mild seasons the flowers begin to expand towards the end of December, which circumstance has gained for the plant the name of Christmas Rose.

There are two varieties of the Black Hellebore—one the common kind, and the other with larger flowers and narrower leaves, and which latter is an Austrian plant, sometimes named *vernalis* in gardens on account of its flowering much later in the spring than the common or broad-leaved kind.

The virtues of the *Helleborus niger* were formerly too much extolled in the old herbals. It is probably now undeservedly neglected, but its use requires great caution, for its effects are very uncertain and dangerous, as it loses its virtues by keeping. Its medicinal uses are as purgatives in cases of mania, melancholy, lethargy, dropsy, and for worms. Snuff made from the dried leaves causes violent sneezing, while if smoked like tobacco it is a good remedy for the toothache.

The roots, however, are the part used in medicine, and consist of a black furrowed roundish head, about the size of a nutmeg, from which short-jointed branches arise, sending out numerous fibres about the thickness of a straw, blackish outside, white or yellowish white within, and of an acrid nauseous and rather bitter taste, exciting a sense of heat and numbness in the tongue, and having a nauseous smell. The root is used in the form of a tincture, but its effects are uncertain and dangerous.—GEORGE GORDON, A.L.S.

(To be continued.)

THE LOVE OF ROSES AMONG THE ROMANS.

THE love of the ancients for Roses was something fanatical. I do not so much refer to the poets; for probably the modern and the antique bards may vie with each other in the use of the Rose as a common-place of poetical illustration; but I allude to a strong passion for the visible, tangible, scent-giving Rose, as something to be enjoyed by all the five senses, scarcely excluding that of hearing, for a rustle of many Roses must have attended some of the more extraordinary manifestations of idolatry. A time without Roses was a contingency to be avoided at any cost; and the Romans, though the mildness of their climate allowed the adored flower to grow at an unusually late season, could not submit to the privations of a winter. Not only were whole shiploads of Roses brought from Alexandria in the inclement season, but various means

were devised for preserving the gathered flowers throughout the year with as much freshness as was attainable.

The wreath of Roses, of which one reads and writes about so often without any other image than that of a curved twig with a tolerably rich supply of floral ornaments, was capable of a high degree of elaboration; for the Roman florists looked upon an enlacement of whole flowers as an exceedingly meagre affair. For a grand work of art they took the Rose leaves separately, laid them over each other like scales, and thus produced a sort of fragrant sausage.

This refinement in the construction of wreaths will show that the luxurious ancients not only insisted on the constant presence of Roses, but were determined to have them in as large a quantity as possible. The anecdotes that illustrate this form of the floral passion could scarcely be surpassed in wonder by the wildest imagination:—"To enjoy the scent of Roses at meals," says Herr Wustemann, "an abundance of Rose leaves was shaken out upon the table, so that the dishes were completely surrounded. By an artificial contrivance, Roses, during meals, descended on the guests from above. Heliogabalus in his folly caused Violets and Roses to be showered down upon his guests in such quantities, that a number of them, being unable to extricate themselves, were suffocated in flowers. During meal times they reclined upon cushions stuffed with Rose leaves, or made a couch of the leaves themselves. The floor, too, was strewn with Roses, and in this custom great luxury was displayed. Cleopatra, at an enormous expense, procured Roses for a feast which she gave to Antony, had them laid two cubits thick on the floor of the banquet-room, and caused nets to be spread over the flowers in order to render the footing elastic. Heliogabalus caused not only the banquet-rooms, but also the colonnades that led to them, to be covered with Roses, interspersed with Lilies, Violets, Hyacinths, and Narcissi, and walked about upon this flowery platform."

As a source of artificial perfumes the Rose was employed by the ancients in other ways than in those oils and waters that are familiar to modern life. When the leaves had been pressed out for higher uses, they were dried and reduced into a powder, called "diapasma," which was laid on the skin after a bath, and then washed off with cold water. The object of this process was to impart a fragrance to the skin. As a medicine, Quinces preserved in honey were introduced into a decoction of Rose leaves; and the preparation was deemed good for complaints of the stomach. In the culinary art Roses had likewise their place of honour, and were put into many dishes for the sake of their pleasant flavour. For this end they were sometimes preserved—a delicate process, as they were very apt to become mouldy.—REV. W. H. E.

GLEANINGS FROM ROCK AND FIELD TOWARDS ROME.—No. 12.

From the inn beneath the Susa mountains we began the ascent of Mount Cenis on foot, hoping to proceed leisurely a little in advance of the carriage, enjoying the pure air and the new flora. We had not proceeded far when a mountain storm overtook us, and we had to run for shelter to a soldier's hut. The soldier made us welcome in the most courteous fashion, giving us seats, and at the same time a great deal of weather wisdom in an unknown tongue. Presently a poor girl, carrying a fat baby, came in for shelter also, and never did I see a more picturesque pair. The girl was dressed in a brown dress, very old and very worn; but round her neck she wore a large gilt cross, and above that a large gilt heart, necklace and earrings. She had several rings on her hands, and on her head a cap of the coarsest linen trimmed with old point lace—very coarse but real, and scrupulously clean. And the baby? The baby, too, had a little white cap, and laughed and crowed at the strangers right merrily.

We had a grand journey up the old mountain amidst torrents of rain mingled with thunder and lightning, which broke at one moment above us, at another below, and again, as it were, in our very faces; while vast armies of cloud rolled majestically to and fro in the valley beneath or about the mountains around us, disclosing now snow-capped peaks glittering like diamonds; now waterfalls scattering their airy spray, across which sunbeams played at rainbow-making; and now a tiny happy valley adorned with beds of the brilliant *Gentiana acaulis*, *Primula marginata* and *longifolia*, with the little *Gentiana pumila* (?)

growing on grassy slopes beside huge walls of snow 12 feet high.

We passed fields full of the lovely white *Anemone sylvestris*, much like our *A. nemorosa* magnified half a dozen times its usual size; and then we came upon other fields one mass of a pale little *Crocus*, which rises into life and beauty directly the snow melts; while here and there the rocks would show beautiful tufts of *Primula marginata*, and the broken walls revealed masses of *Cystopteris fragilis* and *Ceterach officinarum*, with banks of *Polypodium dryopteris* waving at their feet. It seemed like a new world of flowers springing up from a grave of desolation, for nothing could exceed the savage morose look of the scene, saving when a temporary burst of light and sunshine fell on a chosen space. As we neared the top of the ascent the storm concentrated itself into one tremendous explosion, and then rolled away down to the valley beneath, blotting it out from creation, and leaving us a blue sky shining down into a clear lake, which lies outspread on the top of the mountain close by the hospice where snow-trapped shepherds and travellers find refuge, and where there is a chapel and an altar at which the hardy mountaineers may meet in worship.

Every now and then, while making the ascent, we came on one of the twenty-three houses of refuge, built with its thick rock-like wall turning its sturdy back to the road, which in most cases made a sort of shelter for it. I looked in vain for the great dogs of St. Bernard, and yet the houses of refuge are in great request during the winter; but instead of dogs there ran out groups of little children with bouquets of wild flowers, and by never refusing to buy these I used to make a tolerable collection, even when the day was too wet or the roads were too good for flower-hunting.

What I saw of Ferns during this morning's drive gave me an exceeding longing "to do" Mount Cenis leisurely; for the few I managed to procure by making a dash out of the carriage, or by buying from the children, seemed but as the advanced guard of a whole beautiful army lying hidden, like riflemen, in their suit of green, in every nook and cranny of those glorious mountains. How I longed for roots of all I saw I could never tell. What my companions endured in the way of sundry halts after this or that treasure, from petticoats all dabbled in mud and water or fringed with ice, from bundles of cold clammy Ferns with dripping roots being unceremoniously poked into their warm hands with, "I pray you just hold these till I'm settled;" or, "Would you mind taking charge of them? for my bag is throttling me. And where are the trowels? Oh, here in my pocket, or there under you. And the knife? Why, bless me, I forgot to shut it! Do take care." All these pleasures and sundry others—such as cake (the delicious Milanese flat raisin bread which cannot be procured elsewhere), put unawares into the Fern-bag, or the Ferns put into the cake—I leave all this for their pens, not mine, to describe for me. Had I not my treasures, and was I not content?

Why do I thus linger on the mountain-top, seeing visions of the past in the clear waters of the lake? I am taking my last leave of Italy; for almost immediately after leaving the hospice you descend by Fir-clad slopes into Savoy—French Savoy now—so smiling and fertile, one wonders how Victor Emmanuel could ever have found it in his heart to give up such pleasant places.

By-and-by we passed fields literally covered with the *Gentiana pumila* (?) and *Primula longifolia*; and there in the bright sunshine I dug away at the roots to my heart's content, till the carriage was filled with perfume and the siftings of sandy clay, as if we had been navvies revelling in Cowslip tea.

After a while we came to a beautiful valley, through which the river Aar carries its rushing waters in a wild tumultuous manner, while snow-clad mountains rise on every side, only the snow was melted. All at once I heard, "Look up! there is the Mount Cenis tunnel." I obeyed and looked up. We were close upon the village or town of Fourmeaux, between Lans-le-long and St. Michel; and on the left-hand side, far up a giant mountain, I saw two square-framed doors, while perched against the mountain side were the workmen's cottages. Near the square doors is a large semicircular hole, which every now and then vomits forth rocks and stones, which go rattling down the mountain's face. This was the Savoy side of the Great Bore which is to pierce through seven and a half miles of mountain, to make a railway, by which travellers will be taken that they may avoid the sweet air of heaven, laden with the breath of flowers, and be enabled to go rushing to and fro Italy and Switzerland during every month of the year.

A Piedmontese named Joseph Medail for ten years wandered about these mountains, seeking the best spot for this tremendous undertaking; but it was left for a Belgian—Mans, assisted by Sismondi the naturalist, to hit upon the place ultimately chosen. They spent four years in the interesting search.

The outlet, and inlet too, on the Piedmontese side is at Bardonneche, and the workmen are very gradually approaching each other. The two great problems were—how to supply the workmen with air, and how to ensure their meeting in the centre of the tunnel. To let down vertical shafts to ascertain the nature of the mountain and to supply fresh air for the workmen would have taken, it is computed, forty years! Most wonderful are the expedients resorted to for working the boring shafts and for breathing-material. The compressed air of six atmospheres is introduced in tubes—that intended for breathing, of course, expanding the instant it is released; the other forcing out the perforating needle or shaft, much in the same way as a popgun. For compressing the air the torrent of the *Are* is put into requisition. But my poor pen could never properly explain half of the wonders of this most gigantic work; but after gazing up at the perched cottages and inclined planes, I turned my longing eyes back up the valley, with its rushing waters and its fields of Primulas and Gentians; and if ever I go over Mount Cenis again, I think I shall choose the lesser bore of the mules to the greater bore of the tunnel. The cost of this undertaking is perfectly enormous. If finished by 1873, the share to be paid by the French Government alone is £1,287,000.

St. Michel, our next halting place, is one of the loveliest mountain villages I have ever seen. You do not look on the grand hills from afar off in mysterious unapproachableness, for they are close to your elbow, inviting you to scale them at every turn. Nor are they cold, and white, and glittering—too pure for aught but worship. They are rich and warm in colouring, not only courting the sun's rays, but, as it were, imprisoning them on many a glade and chosen spot.

On one of the lower rocks I found a mass of *Asplenium germanicum*, very dry and withered, but retaining sufficient vitality to repay me for my care by sending out new fronds. At first I mistook the withered fronds for *A. septentrionale*, they had been so fine and flourishing; but a little inspection proved differently. I fear for the life of the plants in England, for I have lost all but two in trying to persuade them to live out of doors. On the same group of rocks, but higher up, we found a very handsome orange-coloured Pheasant's-eye (*Adonis citrina*), the *Polygala alpestris*, and quantities of *Silene acaulis*, which gave a ruddy glow to many of the surrounding rocks, from the masses which trailed over them.

At the rambling old inn I found a parcel of alpine plants left for me by our pleasant railway companions of Susa. I wonder if they will ever read this little account, and my grateful acknowledgments with it. At St. Michel we took train for Geneva, changing carriages at Culoz.

Geneva—as I write the name I put down my pen and wonder. How was it that none of the numerous accounts I had read had given me the faintest idea of what Geneva was? For any true impression conveyed to my mind I might have read of Timbuctoo or Yucatan. Yet the clean little town, with the dark green waters of the Rhone for ever rushing through it, with its numerous bridges—its wooden pathways over the river, which laps up to the sides of the houses—with its sober-looking shops and its dark cathedral—has a life and individuality of its own, complete and utterly apart from that of any other place. "To be sure," you will say, "it's the lake, and the Castle of Chillon, and all that sort of thing." No, the lake of Geneva and Geneva are two separate things. I think it's Calvin. When I remember Geneva I feel cold and idle, and very clean and intensely dull. I feel as if I had suddenly passed from one hemisphere to another without crossing the line. The Southern Cross has set, and the northern lights stream up the cold pale sky. I miss from the shop windows the comely benevolent face of il St. Padre, which has given place to the sharp-visaged profile of Calvin. I miss the processions from the streets, the lights, the music, and the people from the churches. I miss the dear old dirty monks, the bells, the noise, the fulness and richness of the southern life; and it does not compensate me to hear that the Genevese are a hardworking set when they are not tipsy, and that life and property are respected, and safe as in England. Perhaps, too, I miss the little excitement of the dark passages and stiletto.

Yes, all this is gone—passed away from me, perchance, for

ever; but there is the lake and Mont Blanc just over the water. Mont Blanc, now clear and sharp in outline, frozen, and white; now grey and misty, looking unearthly in its robe of vapour; now golden red like a bank of lurid fire; and now nowhere. Yes, there is a tiny brilliant peak peering from the clouds; that is the Grand Mulets, Mont Blanc itself is to the right. A little watching, and the three-in-one mountain is visible, but only for a while. Presently all vanishes away, and sky and cloud look entirely innocent of its existence.

Must I speak more of Geneva, or will it be as if a foreigner were to describe Richmond or Hackney? Shall I tell of the wild flowers abounding in the neighbourhood?—of the snow-white *Melissa grandiflora*, the *Tragopogon major*, the *Orchis pyramidalis*, the *Dianthus asper*, and a lovely white *Orchis*-looking plant, with a stiff stem, and buds like closed Orange flowers, that I found in a Beech wood, and which in a smaller variety I once found in a Beech wood in Hampshire, when I was told it was an *Epipactis*, but I do not believe it. Then growing about a waterfall I found the *Pelargonium Robertianum*, and covering an old bridge a lot of *Cystopteris fragilis*.

I took my plants off in triumph to the Botanic Gardens, hoping to name them; but alas! for the system that prevails there, whether that of Professor De Candolle or other! I found obliterated names, dead plants, and disorder everywhere; and after many vain attempts I had to desist in despair, and returned grumbling to the lake and the mountains, which at all times answer every demand and satisfy every craving.

And so at length my little chaplet of Italian wild flowers is finished—my "Gleanings" gathered together and bound up. The sheaf is not large, and there may be here and there cockle with the barley, for there are innumerable difficulties attending even the naming of the commonest Italian wild flowers, from the lack of books and get-at-able botanists; but loving hands and willing feet have followed the reaper's track wherever it was visible. The harvest of the great field of nature is large enough for all. It cries out day and night for labourers. The more the reapers the more bountiful the store, for it knows no years of scarcity and famine, and the very wayside provides food enough and to spare for many gleaners.—FILIX-FEMINA.

WORK FOR THE WEEK.

KITCHEN GARDEN.

In light dry soils progress may be made in putting in some of the principal crops. On stiff wet ground this should by no means be attempted. *Artichokes*, if the weather continue mild give them their spring dressing. *Asparagus*, make new beds with two-year plants, and fill up old ones. *Beans*, plant out Mazagans from boxes and pots. Earth-up the early-sown crops. *Cabbages*, plant out beds, and earth-up those already planted. *Cauliflowers*, plant out from frames or hand-glasses. The latter must have but three plants left in each. *Cucumbers*, the present mild weather will greatly conduce to the health of the plants, as it will allow of an admission of fresh air daily without fear of their receiving injury. Close the frames early in the afternoon, and let them remain shut down till the evening, when a little air may be given for the night. After linings have been renewed keep a constant watch on the state of the bed. *Leeks*, sow for a principal crop. *Onions*, sow main crops in drills or broadcast. Weed and thin out those sown in the autumn. The thinnings may be planted out in favourable situations. *Pot Herbs* should now be sown, or plantations made from cuttings. *Potatoes*, plant early sorts in a warm situation; for earlier crops a few may be planted in boxes in heat, and transplanted to the open ground when they have vegetated. Those growing in frames should have air given freely. *Parsnips*, now is a good time to sow a good breadth in ground deeply trenched, with the manure at the bottom. It is a very useful vegetable, and none better repays extra care in the cultivation.

FRUIT GARDEN.

Proceed with pruning and nailing when not too cold for these operations. If any planting still remains to be done, let it be performed as soon as the ground is in a fit state for that purpose. Do not, as is sometimes done, over-manure. It is a great mistake to induce the production of gross long-jointed wood in any state of the existence of a fruit tree, wood of this description never becomes thoroughly ripened. With stone fruits, gum, canker, and premature death are sometimes the result; and in the case of Pears, anything deserving the name of a crop is never obtained till the gross habit induced by

planting in too rich soil is overcome. Ground intended for fruit trees should first be effectually drained and then trenched to the depth of 2 feet, and if the natural soil is found to be too poor for the health and growth of the trees, a sufficient quantity of fresh turfy loam should be added; but rich stimulating manures should not be used, for they are soon exhausted, and the trees are left to depend upon the natural soil for their support, and when treated in this way never give satisfaction.

FLOWER GARDEN.

As soon as the ground is a little dried it will be a good plan to have all the vacant beds in the flower garden forked over, so as to let the soil become properly pulverised prior to planting out the autumn-sown annuals. Preparation must also be made for a general sowing of the more hardy kinds, such as Larkspurs, Godetias, Clarkias, Nemophilas, &c., which should now be made on the first day the ground is sufficiently dry to admit of sowing them. Proceed with pruning shrubs and common Roses, but leave the more tender kinds until you are sure they will not be injured by frost. The thinning and pruning of young plantations should now receive attention. It is perfectly lamentable to see so many completely ruined from want of this necessary attention at an early stage of their growth. It was in times past totally neglected, and it is in no wise altered at the present day in very many instances. It is an error to plant very thickly of one common mixture, the consequence of which is, that the quick-growing useless sorts soon overtop the more valuable and what ought to be the permanent trees; neglect in thinning, following mismanagement in planting, soon carries them beyond recovery, and they become drawn up like whip-handles, useless either for shelter or profit. Had such been properly thinned in time they would have served the purpose for which they were intended—that is, shelter or ornament.

GREENHOUSE AND CONSERVATORY.

Many plants will soon be fit for repotting. When plants are removed to a higher temperature, examine their roots, and see if they are healthy, and if not, shake the old soil from them and repot them in fresh soil in smaller pots. This is a good mode of preparing plants for the one-shift system, which may be adopted as soon as the roots begin to spread on the outside of the new soil. The one-shift system should never be adopted until you are satisfied that the roots are in a healthy state and beginning to grow. Orange trees in tubs or pots should be carefully examined in order to ascertain whether or no their roots are in a healthy state, and those requiring more room should be shifted at once. In many instances, however, it may not be possible to afford large specimens a shift; in that case remove as much of the surface soil as can be done without injuring the roots, and replace it with a mixture of good loamy turf, broken bones, decayed cowdung, and sand, and see that the balls of the plants are in a moist healthy condition. Dispense with fire heat in the conservatory as much as possible, a temperature of 55° by day and 45° by night will be sufficient for general purposes. Do not allow the heat to rise much by sunshine. There is as much skill displayed in retarding certain flowers as in hastening their flowering in the first instance, and to this end a canvas screen of a thin character should always be at hand to throw over the roof during the mid-day hours of a bright day. Be sure to sow a little Cineraria and Chinese Primrose seed as soon as you can; this, with another sowing in April, will furnish a supply throughout the next autumn and winter, if high cultivation be carried out. Attend to your ornamental trellis plants, they should always be in fine condition, and, to accomplish this, attention is necessary. Forcing-bulbs, as Hyacinths, Narcissus, &c., should, after blooming, have their leaves tied up, and should be transferred to a cold frame, and, when the most severe weather has passed away, they should be turned out of their pots to feed in prepared beds.

STOVE AND ORCHID-HOUSE.

Continue repotting such Orchids as need that operation. Stanhopeas, Acroperas, Dendrobiums, &c., suspended in baskets or on blocks will now require syringing occasionally, or watering by some means. Many of these will have received little water since the end of October, and will have become excessively dry. Blocks may occasionally be soaked for a few minutes overhead in tepid water, also baskets, if very dry. If syringing is resorted to, choose a bright sunny day for the purpose. On such occasions keep up a brisk fire, and give air freely in the afternoon, for fear of the moisture lodging on the unfolding bud, which, in some cases, would prove injurious. The temperature should now be allowed to rise freely on bright

days, remembering that a rise by solar heat alone can do no harm for a few hours, even at this period, provided it do not exceed 75°.

FORCING-PIT.

Continue to increase atmospheric heat and moisture at fitting periods. Attend to plants for succession, watch for the worm in the bud of Moss Roses, fumigate for thrips, &c., and see that the plants are duly watered with tepid liquid manure.

PITS AND FRAMES.

Some little water will now be required here, give plenty of air all night in safe weather, and propagate stock for bedding out. Endeavour to keep the air of the pits and frames as dry as possible.—W. KEANE.

DOINGS OF THE LAST WEEK.

Fitness.—"Have a place for everything, and keep everything in its place," is a capital axiom and should ever be kept in mind by the gardener, though in these days there is scarcely one in ten who can carry out the principle. It does one good to go to a place and find a separate house for every particular section of plants, and in which, therefore, throughout the season they can receive that kind of treatment as respects temperature, moisture, &c., which their circumstances require. No such treatment can be given where in two or three houses almost everything must be attempted. Hence, the complaints of plants being drawn, unhealthy, troubled with insects, covered with mildew, &c. If a nice conservatory is to be kept gay all the winter, the stove, the greenhouse, the forcing-pit, must all be made to contribute their share; but the due health of the plants must be maintained by keeping them there only so long as they are at their best, and then removing them to the place, where they will have what they need most. Years ago we had fine displays in winter by means of Justicia, Begonias, Poinsettias, Euphorbias, winter-flowering Heaths, Epacris, Camellias, Cinerarias, Chinese Primroses, double and single, forced shrubs, bulbs, &c., but to keep these in one house required some care in grouping, and placing the hardiest where most air could be given; and even then the average temperature at night being seldom below 50°, and oftener nearer to 55°, with a rise from sunshine when it could be obtained, some of the hardier plants, as Cinerarias, required extra care to keep them clean and bushy. We think it but just to mention this, as some enthusiasts with little room, but who must try everything, complain very much that their plants are very much drawn this winter, which in most of the cases where any explanation is given, we would at once attribute to the plants being kept in too warm and close an atmosphere, and at too great a distance from the glass, and especially when the roof is at all embayed by creepers. The winter, too, as a whole, has not only been extremely damp, but also very sunless, and that would occasion the spindling-up of plants under glass, when not neutralised by giving extra air, without allowing moisture to come in with it.

In such cases the injunction so often given, "Keep the plants near the glass," is all very well; but in the usual run of plant-houses, if a portion of plants are thus privileged, what becomes of those that must be on beds, or stages, many feet from the glass, and in many cases shaded, too, by creepers? One advantage as respects the latter is, that with the exception of winter-blooming plants the other creepers that chiefly bloom in summer may be pretty well cut-in in autumn, so as to allow all the light possible in winter.

Keeping Plants close to the Glass is also worthy of the consideration of those whose want of that success at which they aim is chiefly owing to their attempting to have two or three distinct crops of plants on different levels in the same house, one tier above another, like the floors of a house, whilst the sun through the glass lean-to roof can only admit full light to the top tier or storey. We have done as much with storeying and cramming in one house as most people, and from necessity, in order to effect certain results with little room; but no contrivance, except moving the plants, could prevent the lower shaded storeys or tiers from becoming weakly, if enough of heat reached them to cause them to grow. Some people seem to think that they can have tier above tier of plants in a house, just as they have tier above tier in a draper's shop. They forget, that though such soft goods are often the better of having but little of the sun, light for the generality of plants is the great essential for a healthy existence.

Keeping growing plants close to the glass is, therefore, of

more importance in pits and frames than it is in the case of lean-to houses with front glass. In the case of pits and frames there is no light, except what comes directly over the tops of the plants, no side light whatever reaches them, and, therefore, the tendency to be drawn up weakly will just be in proportion to the heat applied and the distance the plants are from the glass. The position of plants in a pit must, however, often be regulated by other considerations. If the pit or frame is shallow, the plants will be exposed to sudden extremes, just as they are placed close to the glass: hence, even on the score of safety, it is often desirable to have the bulk of the plants near the back fully a foot from the glass, and to place other plants near the front that would for a time rather enjoy the shade. There are fine-foliaged plants, too, which often enjoy a diffused rather than a shaded light, and these may receive what they want by standing farther from the glass. By acting on this principle shading may to a great extent be dispensed with.

An amateur, a thorough admirer of the "close-to-the-glass principle," informed us two years ago that in following our mode with his *Calceolaria* cuttings he put them in in a cold pit in October, and that they were not more than 4 inches from the glass. He was resolved to have them bushy, but the very proximity to the glass necessitated shading at first, which was rather against bushiness, and worse than that, the want of covering in a cold frosty morning caused them to be much injured by frost, so that he came to have doubts as to the "near-glass principle." Our correspondent, who will see this, will excuse our referring to it, merely as an evidence that a good idea may be carried too far. We generally put our cuttings out at a distance of from 12 to 15 or 18 inches from the glass. This season we did not insert them until the end of October and the first days of November. They are watered as inserted, but they seldom or never have any shading. In fine days the sashes are drawn off, in mild days tilted; and if a sudden unexpected frost should come there will be fully a foot of air beneath the glass to freeze before the cuttings are touched: hence, even for plants in pots that have to be pretty near the glass in pits, they will be less subject to sudden extremes if the pit is deep enough to permit of a platform being placed in it, so that there may be air below the plants as well as above them.

But if this old rule about keeping plants close to the glass should be followed with prudence, even in lean-to pits, it may be regarded as perfectly obsolete in all span-roofed houses with glass at the sides as well as on the roof. A stage or shelves in such a house is more a matter of adaptation and convenience than of sheer utility, so far as light is concerned, more especially if large squares of glass and light bearers are used. In such houses plants will thrive as admirably on the floor as they will do on a stage, *if, in either case, there is nothing above them to intercept the light, and, in either case, ventilation is sufficiently under control.* Whilst, therefore, the advice about keeping plants close to the glass must be attended to in old dark houses and pits, it will become pretty well obsolete in the case of new light airy houses. Even in such houses pretty well all glass, if there are plants on the floor, a stage about 3 feet above the floor filled with plants, and the roof shaded with creepers or a fair crop of Grapes, we should expect the plants on the floor to become very spindly when they had enough of heat to make them grow. In a comparatively dormant state many plants could be kept there. To meet the case of many inquirers as to how to obtain Grapes and flowers out of their one house, and both good, and without interfering with each other, we shall have a few words to say ere long. Meanwhile, instead of lofty houses, we have no doubt that lower ones with light all round will become more general for plant purposes, unless where heat and fuel are primary considerations, for then the opaque wall of a lean-to house constitutes an advantage.

KITCHEN GARDEN.

Much the same as last week. Nothing could be done with advantage except wheeling on a frosty morning, followed as we expected by a drenching afternoon. On the same morning, the ground being a little hard, cleared away a few decayed and yellow leaves from Brussels Sprouts, Savoys, &c., as a few of them, especially in muggy weather, are sufficient to taint the atmosphere of the garden. Threw wood and cinder ashes over Lettuces, &c., to keep slugs from them, and hardened off with plenty of air Peas and Beans under protection, so that they can go out in good condition as soon as the ground is dry and friable. Cut off the heads of Turnips in store, and did

the same with Carrots, as the mild weather is causing them to shoot prematurely. Gave abundance of air to Radishes, young Carrots, &c. Radishes in the open air had better be covered every night, the weather is so uncertain. Gave a little more room to Kidney Beans bearing in pots. There is nothing gained by having them too close together. Kept up successions of Sea-kale, Rhubarb, and Asparagus. As we wanted the spare room in a heated pit for forcing and propagating purposes, placed soil in the bottom for Cucumbers, and then plunged in it large pots with strong bushy plants of Cucumbers showing fruit. They will fruit more freely and early from the cramping of the roots in the pots, and the hole at the bottom is sufficiently large to let out the roots ultimately. By this means we make better use of any part of the pit unoccupied, than if we planted out the Cucumbers in the narrow border. All plants turned out in a bed or border suffer less or more when other plants in pots are set on the surface, as the watering of these pots promotes an unhealthy state in the border beneath them. These matters are worthy of notice when every inch under glass has to be made the most of. Partly from necessity at first, and now from choice, whether in pits or frames, we now keep the roots of Melons and Cucumbers chiefly in a space of from 2 to 3 feet in width, instead of their traversing all the width of the bed, and we have less trouble and rather more fruit in consequence.

FRUIT GARDEN.

Much the same as last week; ground too wet and clammy to do much out of doors. Proceeded with dressing and tying trees in orchard-houses. The trees against the back wall are tied to nails driven in the wall at regular distances, and remaining stationary as so many studs. Tying is not so easily done as when wire trellis is used, but the expense is far less, and there is no trouble with shoots behind the wires. The studding with cast metal nails at once is far superior to using nails and shreds in the usual mode of fastening, as the shreds are a constant harbour for insects and their eggs, and every nail-hole becomes a nest for such enemies. In driving in the nail-studs, 6 inches apart every way is a good distance; and when metal nails are used a large space of wall can be done for little money. When we thus used nails as standing studs, we heated a lot of nails on an old useless shovel placed over the fire, and then turned the hot nails into oil, and when cool spread them out to dry. If these be coloured, when the wall is covered there will scarcely ever be any appearance of rust upon them. In all other departments allowed growth to come on slowly, so as not to be weakened in the dull weather. (See remarks on temperature a few weeks back.) Planting fruit trees should be finished as soon as the weather will permit. A little frost will now do great good in keeping back the buds of fruit trees out of doors, and will most likely be accompanied with more sunshine to benefit what is further advanced under glass. A steady uniform heat should be maintained about Pines showing fruit. Plants in pits and frames should have linings well backed-up back and front, when dung is used for heat, so that the atmosphere may be warmed without the heat passing through the plunging material of the bed. Such dry top heat is of importance in all such moist dull weather. For Melons, especially early ones, much depends on having a nice atmospheric temperature at an early period, without running the risk of making the bottom heat too strong to be healthy. When dung heat, or that from any fermenting material, is used, this top temperature is easily supplied by banking fermenting material round the pit or frame. Will prune and nail trees out of doors as soon as we can.

ORNAMENTAL DEPARTMENT.

In dryish places proceeded with planting trees and shrubs, and this was better done on grass-covered ground than on that which had come under the influence of the spade or the plough, as the ground is still very wet. Gave plenty of air to *Calceolarias* and other half-hardy plants in pits. Filled vases, &c., with bulbs for the mansion. Did little with the lawn or walks. Notwithstanding care, some *Primulas* in the conservatory have damped and become unsightly, owing chiefly to drip from the roof. Violets in pots under glass required plenty of air. Auriculas that have become too damp from drip should have the drainage examined, a part of the surface soil removed, and its place supplied with rich fresh compost. Everything comparatively hardy, but under glass, should now be kept as robust as possible, by plenty of air in mild weather.

Air-giving.—Such a winter as we have passed through does much to show the importance of a heating apparatus in all kinds of plant-repositories, as a little artificial heat during the

day would dispel all damp, and insure a circulation of air. As already stated, when one house is made a flower-house, the plants requiring the highest temperature should be kept at one end, and no air given there, whilst air should be admitted close to such plants as Cinerarias and Primulas. In common greenhouses forced plants should be treated in the same way, at least until they are hardened to the atmosphere in which they are placed. In more average-temperated greenhouses hard-wooded plants, as Kennedias, Boronias, Hoyas, Leschenaultias, Croweas, and the most tender Pinneleas require a closer and warmer atmosphere, and more direct light, and less direct air coming at once upon them, than would be agreeable to Acacias, Cytruses, and softwooded plants, as Pelargoniums and Cinerarias, and the general run of Heaths. One reason why a collection of Cape Heaths is best grown in a house by itself, is that they require a very free circulation of air, even if not much above the freezing point, which circulation at that temperature would soon be fatal to a Crowea or a Boronia. Many a fine hardwooded plant from Australasia has been destroyed from standing just behind an opening for air in front of a house in cold weather, when hardier plants would even have enjoyed the draught. We are quite well aware that such plants in their natural habitats often pass unharmed through a degree of cold to which they would be rarely subject in our greenhouses; but we must not forget that the fierce cloudless sun in such climates in summer gives a hardness and induration to the wood which it can hardly acquire under any circumstances in our more moist and clouded climate. Besides, we are too often led to forget the effects of a draught of cold air. It is a very different thing from exposure to the cold without the draught. We have known instances of delicate young ladies, aye, and young gentlemen too, who would pass from a heated ball-room, and with little more than a loose shawl or mantle in addition to ball-room clothing, and traverse the gardens and parterres of an evening, and with scarcely a perceptibly injurious effect; but, alas! we know of instances under such circumstances in which, when oppressed with the heat of the rooms, sitting for fifteen or thirty minutes in the agreeable coolness from the draught of an open window, has but too surely left its mark in the hectic consumption and the untimely death.

Had we again the chance of growing a good collection of the hardwooded tenderer Australasian plants, except in extremely mild weather they should never have air directly beating upon them from the front of the house, unless it was heated before it reached them. They would have all that would be necessary for them from top air alone. As a general rule, in ordinary circumstances, with all such tender hardwooded plants front air should be given sparingly in winter. A very slight opening at the apex will in general soon set all the air in a house in motion, and the heated air that escapes will heat and moisten the heavier and colder air as it passes through it. Some time ago we were asked to look at some nice cottages for labouring men. Strange, the windows that did not open from top to bottom were in two halves, the upper half a fixture, the lower half lifting up so as to give what air was wanted about 2½ feet from the floor. The hundred or so of windows, we are glad to say, were altered, so that the upper sash should pull down. An inch even in a cold day would soon change the atmosphere of a room, and if a person were at a respectable distance, he would enjoy the fresh air without being cooled by it. The throwing up of the lower sash admitted the cold air from without to mix at once with nearly the coldest air of the room. Hence for all glass-houses we look upon top air in ordinary circumstances as more suitable, and especially in winter, than front air, which should always be admitted with care and caution. If the stimulus from expansion from heat is regulated by the presence of bright light, the whole theory and practice of ventilation will be reduced to its simplest proportions; unless in extreme cases, sunlight, and sun heat along with the light, will not make plants weakly or diseased. In such favourable sunlight the chief danger to be guarded against is scorching from the want of early air-giving; and make sure if a rather high temperature is reached, that it rises gradually, and after air has been given. The giving a little early is of more importance in every way than giving much at a time, and often when too late. Went on potting, &c., as detailed in previous weeks' notices.—R. F.

TRADE CATALOGUE RECEIVED.

H. N. Bransby, High Street, Alten.—Catalogue of Select Vegetables and Flower Seeds.

COVENT GARDEN MARKET.—FEBRUARY 17.

In consequence of the continued open weather, there is a constant and liberal supply of winter vegetables, and there is likewise a large increase in our importations, among which are some fair samples of Green Peas. Prices rule much the same as last week. Pines are more plentiful, and a few Strawberries are coming in.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

FERN MANUAL (G. G.).—There is no enlarged form.

MEALY POTATOES.—G. P. will be greatly obliged by "W. Ross" stating when and how he applies the alkalies he recommends. Should they be spread upon the soil and dug into the earth some time before planting the Potatoes, or should this be done just at the time of planting?

VINE-BORDER.—RIBBON-BORDER (X. Y. B.).—We would do nothing to your border. Leave theatched covering, it will be all right. When rabbits are troublesome a Geranium-border would look very well in four lines, with the sorts you name planted thus—Golden Chain, Flower of the Day, Tom Thumb, and Madame Vanher and Mangles, mixed, for the back row. If Flower of the Day were small, and Golden Chain were large, we would transpose them, placing Flower of the Day in front.

RIBBON-BORDER (J. C. E.).—Of your two arrangements we prefer this—1st row next the glass, Cerastium tomentosum, white; 2nd, blue Lobelia dotted with Geranium Cloth of Gold, blue and yellow; 3rd, Flower of the Day Geranium, scarlet and white; 4th, Christine, pink; 5th, Stella Nosegay, scarlet; 6th, yellow Coleolaria; 7th, Ageratum, alternately with Zelandia Dalia, blue and purple. This plan would look very well if the flowers were taken off Flower of the Day Geranium. For the seventh row, Ageratum or Zelandia Dalia, would be more easily managed if only one of them were used for the row. The same remark will apply to the second plan. We like the first the better.

BOOKS (E. E. B.).—For the management of plants in the greenhouse, &c., Keane's "In-door Gardening;" for plants in the garden, Keane's "Out-door Gardening" will suit you. You may have either of them free by post from our office by enclosing twenty stamps with your address, or forty stamps for the two.

ORCHIDS FOR A NORTH HOUSE (S. L.).—When speaking of those at Mr. Low's nursery, I mentioned them as instances of cool-house growing, so that I cannot say whether such would suit "S. L.'s" stove. He might, however, try Lycaste Skinneri, Barkeria spectabilis, saphronitis grandiflora, Odontoglossum grande, gloriosum, &c. If he apply to Messrs. Backhouse, of York, they would send him his catalogue, in which he will obtain a great deal of information, well and clearly put.—D. Deal.

ROSES (F. L.).—If true to name several are very good, but some are very old. Duke of Cambridge, William Jesse, and La Reine are Hybrid Perpetuals. Chénéole, General Allard, Madame Plantier, Duke of Devonshire, and Dauphine, Hybrid China, &c.; Shakespeare, and Alphonse Maille, Gallica; Eugene Hardy, China; and De Candolle, Moss.

LAPAGERIA ROSEA COMMENCING GROWTH (W. A. O.).—Your plant will now, as it is pushing up, now shoots the size of the little finger, require to have the soil kept wet (and it never ought to be dry), increasing the quantity as the growth may render necessary. Water, therefore, and encourage growth.

RENOVATING LAWN (Salterton).—About the middle of next month apply a dressing of rich compost, or very old rotten manure, so as to cover it from a quarter to half an inch thick, prior to which the bare places should be pointed over with a fork so as to loosen the soil. Distribute the compost evenly; and, as early in April as there is a prospect of rain, sow over it the following mixture, scattering a quantity over the bare places first, about double that given in other places.—*Festuca rubra*, 6 lbs.; *Festuca tenuifolia*, 4 lbs.; *Festuca durinacula*, 6 lbs.; *Cynosurus cristatus*, 6 lbs.; *Poa nemoralis*, 4 lbs.; *Poa pratensis*, 4 lbs.; *Lolium corniculatum*, 2 lbs.; *Trifolium minus*, 4 lbs.; and *Trifolium repens*, 4 lbs. As you have tried at various times laying turf we give you this heavy seeding, and we think the result will be a good lawn of fine turf. The quantities named are for an acre; you will, therefore, have to take proportional parts of each Grass according to the extent of ground to be sown. After sowing rake with an iron rake, and roll well immediately afterwards. You must sow and roll on a dry day, and if rain fall at night, or on the next day your lawn will soon be green. Keep well rolled after June, and do not mow before that time. If you have the bare places lightly scratched, sow the seeds, and then manure, the seeds will very likely be buried too deeply; they will grow much better bare than covered deeply with soil, in which case most of them will perish. White Clover bears dry weather well, and, so far from its being the first to go, stands with us after the Grass has been burnt up. It, Yellow Suckling Clover (*Trifolium minus*), and Bird's-foot Trefoil (*Lolium corniculatum*), last year and the year before grew so well on our dry light soil over gravel, as to render the lawn quite green after the Grasses were apparently burnt up.

FORMING GRASS STEPS (An Old Subscriber).—We made some steps of grass in the autumn of 1864 in precisely the same manner as your gardener, and upwards of an hundred yards of the sides of a terrace, and the grass not only withstood the drought of 1865 without becoming brown, but now forms as green, firm, and close a turf as that upon the level. We think that the sides of the steps have been made perpendicular, and in that case the turves might bludge out, and, consequently, would not unite well to the soil. Had they been slightly on the slope, (our steps are 9 inches in height, and slope from the perpendicular from 2 to 3 inches in that height), been beaten firmly at first, gone over once or twice after the first rain, and watered occasionally in dry weather, we think the sods would have stood instead of crumbling down. We have steps green enough in which the risers are quite perpendicular, but these are not nearly so fine as where slightly on the slope. If you were to have the whole relaid, the best method to adopt would be to put the sods on large enough to reach from the top of the step, beginning at the back, down to the next step, the soil being previously made rather loose on the surface, to lay them when the ground is moist, to beat firm, and to allow an inch or two of slope on the upright part. Ours done in this manner stand well and look well. If you make little holes, say a quarter of an inch deep and half an inch apart, scatter grass seeds in them, and then slightly scratch with a rake, afterwards beating, grass will probably cover the steps in time, but turfing would be by far the best course to pursue. Our steps lead to a croquet lawn, and are subjected to much wear and tearing during the season. Allow a little slope and all will be well; it is the roots that hold the turf and keep the soil from crumbling down.

HOTBED ON VINE-BORDER (Tropicus).—You may make a bed of dung upon the Vine-border, and so far from injuring the Vines it will have the contrary effect. The only injury that can possibly result will arise from treading upon the border. There is no danger of burning the roots of the Vines. You cannot possibly make the bed so hot as to do that. Boards should be placed on the border to walk upon.

PROPAGATING-CASE (Idem).—The Bijou and Wardian cases are the best, and they may be had furnished with heating apparatus complete. They are very useful for raising plants from seeds and cuttings, and keeping them in winter. We do not know the prices of them. Mr. Gray, horticultural builder, Danvers Street, Chelsea, would furnish full particulars on request.

HARDINESS OF PLANTS (Idem).—Of the plants named by you, you cannot grow *Dianthus* in a temperature of from 38° to 40°, except *D. australis*, *D. Cordylifolius*, *indivisa*, and *D. Veitchii*; or *Stephanotis*, *Caladiums*, *Eucharis*, *Hoyas*, *Gardenias*, and *Ixoras*; but *Mandevilla suaveolens* will do if not kept wet. The Orange tree will do well. The others must have a stove of not less than 50° in winter, 55° being more desirable. *Caladiums* require a temperature of at least 60°.

GRAFTING ORANGE TREES (H. M. L.).—From the middle of March to the end of April is a good time to graft orange trees. The most eligible method is inarching; but whip-grafting will also answer. In the latter case the stocks should be plunged in a bath of about 70° in the middle of March, and in ten days they will be ready for grafting. It was not necessary to pot the stocks, as doing so only makes them take up more room. The atmospheric heat should be from 50° to 55° at night, and the atmosphere close and moist. Leave on the stock a few eyes above the graft to draw the sap into the scion. Employ whip or side-grafting with a tongue, and in addition to covering with clay, cover with moss over the clay to keep it moist. The best soil for Orange trees is loam from rotted turves a year old, with one-fourth well-rotted manure, adding sand according as the soil is light or heavy, so as to render it friable. Keep in heat until the grafts begin to grow, then cut the head off the stock down to the graft, and loosen the matting, covering, however, again with moss, and after the growth has fairly commenced remove the plants to an airy greenhouse.

GUTTA PERCHA—INDIAN-RUBBER (A. A. Y.).—Gutta percha is obtained from the sap of a tree called *Isanandra gutta*, a native of Borneo and other islands its neighbours. The bark is wounded, the sap exudes, is collected, and soon hardens. Indian-rubber, or caoutchouc, is obtained chiefly from the sap of the *Siphonia elastica*, a tree found in Gambia and Brazil; but there are some other trees which produce it. It is obtained in the same mode as the gutta percha.

GROWING CUCUMBERS IN A FRAME (A Subscriber, West of Ireland).—We think you would have a good crop of late Cucumbers without more artificial heat by proceeding as follows:—Take out another foot of soil from the inside of the frame, and thus make it 3 instead of 2 feet deep, and in June place 2 feet of hot dung in the frame, cover with 3 inches of soil, and place in the centre of each light half a barrowful in the form of a cone with the top flattened. When the mounds of soil are warmed through turn out a couple of plants in each, watering, &c., and in a fortnight cover the whole of the bed 9 inches thick with soil. The linings against the brick wall would do little if any good. To husband the sun heat you must give air early in the morning, and close early in the afternoon; and if it be done so that the heat does not exceed 90° after shutting up, you have not closed too early. A sprinkling of water at the time of shutting up is advantageous, and keeps red spider in check. Keep well watered, but do not soak the soil.

VERONICA SPECIOSA TRAINING—HONEY-SUCKLE STRAGGLING (Idem).—The shoots of the Veronica should be thinned out, cutting away quite closely the weakest, those which have flowered, and the foreright shoots. Leave sufficient shoots to train-in, nailing or tying them so as to cover the wall evenly in every part, and keep them well tied-in as they grow. Do not overdo the branches by training them too closely, but allow room between each for light and air. After August the shoots, with the exception of the leaders, may be permitted to hang loose. The Honey-suckle should be trained to the wall, cutting out the old weak wood, and distributing the rest regularly, and not too closely together. In summer remove the straggling growths, and keep those required to fill vacant space neatly nailed or tied-in.

FORWARDING POTATOES FOR AN EARLY CROP (Idem).—You cannot do better than take a box about 3 inches deep and in it pack the sets closely together, eyes upwards; then place it in a corner of your hobbed, and cover the sets with a piece of cotton or old calico. They will soon make sprouts from half an inch to an inch in length; then remove the covering, and take the Potatoes to your dwelling for a few days to harden, and when hardened off plant in the open ground. Do not lay them on the dung and cover with soil; they will rot, and be difficult to separate when required for planting, and, besides, it will not do to take them from a hotbed and plant at once in the open ground.

BOIS-IMMORTEL (H. G.).—This tree, used so commonly with the Plantain to shade the plantations of the Chocolate nut, we believe to be *Erythrina umbrosa*. We never met with the name *E. coccinea* in any botanical authority. Stendel in his "Nomenclator Botanicus" has no such synonym. We have no *Burmeese Flora*.

DESTROYING WEEDS ON GRAVEL WALKS (W. H. C.).—As you have tried salt, and do not wish to have the walks tarred, we can confidently recommend the following as the best and cheapest known method of destroying weeds on gravel walks:—Dissolve 1 lb. of powdered arsenic in two gallons of cold rain water, put it in an iron pan over a fire, and stir until the liquid boils, then add nine gallons of cold water and 2 lbs. of crushed soda, stirring all the while until the whole boils, and then keep boiling slowly and stirring briskly for half an hour. Apply the hot liquor to the walks in dry weather by a watering-pot with a rose that will allow of its equal distribution. A good soaking is necessary, but the liquid should not be poured on so long as to run to the grass or Box-edgings. The quantity named is sufficient for thirty square yards. It should be applied before the weeds have grown much, in April or May. To keep it from the Box-edging a board should be laid against this, and inclined so as to throw any water that may fall upon the board on to the gravel, and the same on the other side next the grass, the boards being supported from behind. Where the walks are wide and extensive a water barrel with a tap behind may be used, and a perforated tube to distribute the water, and in this way the work is expeditiously performed. Care should be taken to protect the edging as already directed. Those employing this liquid should be careful to keep it beyond the reach of animals.

ARRANGING FERN CASE (D. Davis).—We do not know where miniature rockwork for Fern cases can be purchased; but you may make it yourself of pieces of porous limestone or sandstone, whichever you can obtain, cemented together. You may form the rockwork according to your own taste. You may have it high at the ends and again in the middle; but it should be confined to one side of the case, and it will then appear to form a background. You must provide a bottom of zinc or sheet lead to the case, and it should incline to one end. There should be a hole there, and a piece of lead pipe furnished with a tap to allow of water being drawn off. We have had a false bottom made of zinc, with a quarter-of-an-inch hole to every square inch. The edges of this false bottom were turned up an inch all round, and a strip of zinc an inch wide was soldered on in the centre. The false bottom being inverted left an inch cavity beneath it; and the water was let off by the lead pipe once-a-fortnight or so. We find that it answers nearly as well to place on the bottom an inch of sandstone in pieces about the size of a walnut, on these half an inch or so of moss or cocoa-nut fibre, and on this the compost for the Ferns. The water drains from the compost among the stones, and, passing to the lead pipe, is drawn off when necessary. The bottom may have holes in it, and it will answer as well; but to prevent the water dripping on the floor the closed bottom, lead pipe, and tap are necessary. In a miniature pond in the centre you may have a plant or two of *Vallisneria spiralis*; and have floating on the surface a few plants of *Lemna minor*, but not so many as to hide the water. A newt and a few water snails will make all complete.

PTERIS TRICOLOR CULTURE (An Admirer).—We think that your plants have not sufficient heat. In summer they require a temperature of from 65° to 85° to make anything like good growth, and they winter safely in a temperature of 55° from fire heat. In one of 50° they will live, and even in one as low as 45°, but such a low temperature is not good for them. However warm the plants are kept the old fronds will become brown in winter. Bottom heat is not needed, and that, if from 60° to 65°, will do no good, and may do harm by keeping the soil very wet. If you place the plants at the end of next month in a moist growing heat of between 60° and 65° by night, and of 75° and 80° by day, keep shaded from bright sun, and pot them when they require it, we think you will find a difference. Secure good drainage. Your compost is good, providing the peat is fibry brown peat and not dark brown, which when wet is like so much mud, and the loam should be turfy yellow loam. The proportions should be two-thirds of peat, one-third of loam broken or chopped with a spade, but not sifted, with the addition of one-sixth of silver sand.

EGG-PLANT CULTURE (*N. B. Glascock*).—Sow the seeds about the middle of March in a compost of turfy loam and one-fourth leaf soil, and place in a hotbed of from 70 to 75°. When the seedlings are sufficiently large to handle, prick them off singly into small pots, and continue them in the hotbed, giving abundance of air after they become established, and keeping the soil and air moist so as to encourage free growth. When the pots are full of roots shift the plants into pots a size larger, and afford a temperature of from 60 to 75, or 85°, with air daily, and a position near the glass. A shelf in a viney is as good a place as any. Continue to shift into larger pots as may be necessary, using a compost of turfy loam from rotted turves, and one-fourth rotten manure. Good drainage must be secured, especially at the last potting, which will be from six into eight-inch pots. The plants require plenty of air and a moist growing heat, and being kept clear of green fly and red spider, they will grow freely, flower, and set their bloom; the points of the shoots are then to be pinched out, and the fruit thinned to two or three on a plant. Supply with weak liquid manure at every alternate watering, and the fruit will attain the size of a hen's egg, and the plants may then be removed to a greenhouse, and, indeed, they may be grown there after being removed from the hotbed, if kept in a light, moist, and airy situation. The main points are to keep them growing freely until a good plant is obtained, and to keep them free of aphid and red spider in all stages of their growth.

PRIMULA FILICIFOLIA RUBRA NOT FLOWERING (*W. J. O.*).—This variety is not a shy bloomer; if flowers quite as freely as the white variety, but is later, as the red-shaded varieties invariably are. Do not overpot, but give weak liquid manure in place of too much pot room. Never mind about their not flowering. You will have a fine plant and much finer bloom than were the plants to flower early and whilst small.

CUCUMBER LEAVES INSECTED (*E. C.*).—We have examined narrowly and find no insects on the leaves, and yet we are almost sure that you have thrips on them. A very small insect, long for its width, and which will be sure to jump if you examine the backs of the leaves narrowly. Besides that, however, the leaves exhibit traces of scalding, or burning, which might be occasioned by too much heat in dull weather, and an hour's sun on the leaves whilst they were damp, and before being dried by air. The burning might be caused by the roots being too hot, or coming in contact with the hot pipes for bottom heat, which they might do on one side of your house according to the sketch given; or by a strong heat in the pipes for top heat and no air, as these pipes are coated with sulphur and lime. It is very possible to throw off too strong fumes from pipes thus encrusted with sulphur, and especially at this dull season. When so encrusted the water in the pipes should be rarely above 150°. We by no means infer confidently that this is the cause, as you seem to have abundance of heating power for an eight-feet-wide low span house. We feel sorry that you should have been so troubled after the care you have taken to wash and clean the house. We are still more sorry that we can hold out no prospect of cure, if the leaves generally are at all as bad as those sent. If the plants are strong, the best plan would be to cut off all the leaves and burn them, taking them off close to the stem, but hurting no buds. Doubt the cut parts next the stem with a powder formed of lime and charcoal. Let the soil become rather dry. Do not syringe the stems, but keep a moist atmosphere and the usual heat, and give a slight smoking with tobacco, repeated two days after the first, and shade from bright sunshine. If the plants break strongly you may succeed in obtaining a good and an early crop; but there is just the chance that all your efforts will fail, and hence the importance of at once making another sowing. Of course, when the plants break strong, they must gradually receive the usual quantity of moisture; but a very moist state of the soil, after removing most or all of the large leaves, would prevent the plants throwing out healthy shoots. It is better to feed the stems, as it were, through a moist atmosphere. We have found several times that Cucumbers appearing like yours would do wonders after being treated as above. The stems might be washed with a sponge and clear soft water at 80°. The sponge must be used carefully so as not to injure buds or incipient shoots at the axils of the leaves removed. Once we had a lot of Cucumbers with all the large leaves worse burned in appearance than yours, by means of the bursting of an old line near them. By removing every leaf larger than a florin-piece, and treating as above, in less than a month the plants bore no trace of the disaster. It would be well, however, to secure fresh plants, as we did.

PRESERVING FLOWERS.—*J. B.* would be glad to know if flowers should be dried before dipped in glycerine.

APHELEXIS CULTURE (*A. Notices*).—An article will be published shortly.

CHIMONANTHES FRAGRANS IN POTS (*G. S.*).—We have flowered the *Chimonanthus* in a pot; but it requires a very large one, good loam, with a little peat, plenty of water in summer, and a warm sunny place in the autumn, and the water to be reduced then to harden the wood. It requires much the same culture as a spurred Currant tree would do, only that the young stubby shoots are what must be looked after and prepared for winter. If a plant has several stems now, and they are bristling with short shoots, these may all be cut in to a bud in the end of March. Ere long they will push; if the shoots come strong, pinch them back, so as to obtain two instead of one. If the shoots produced are of the size of from a crowquill to a goosequill they will be quite strong enough; and if these side shoots grow longer than from 8 to 10 inches nip out the points. Treat them much in the same way as Mr. Rivers treats his fruit trees in pots. If the shoots are too thick to obtain light enough, thin them out. Give all the heat possible out of doors in autumn, and as much dryness as the plants will stand, to ripen the shoots. If the plant must stand out in winter protect the roots with litter. As the soil becomes damp and the weather is mild, the buds will expand. When done flowering, prune as before.

INSECTS (*Watsonian*).—Your larva is that of the well-known and most destructive weevil, *Otiorynchus sulcatus*. We know no better remedy than that of carefully sifting the earth in your pots and picking out the grubs, which are easily seen from their pale colour. A careful inspection of every pot should be made, and the earth stirred round the base of the stems, as it will be too late to take these precautions when the plants show signs of being attacked, by lagging. W.

TREES AND SHRUBS FOR A WET HOLLOW (*Mrs. F. S.*).—For the low-lying ground, formerly a pond, and filled up with stish soil, about a quarter of an acre in extent, and which will always be rather moist, backed now by trees on all sides except that fronting the house, which stands on a much higher level, the planting of the old pond must depend something on the trees already round it, and whether it would be desirable to make that harmonise with the other trees or to assume a distinct character of its own. In the latter case a quick and pleasing effect would be produced by using Willows and Poplars for light foliage, either without or in combination with some sombre-leaved Pines, and with an undergrowth of evergreens and other plants if desirable. Thus in such a place, first there might be planted three good plants of the Babylonian or Weeping Willow, one of the White and two of the Duke of Bedford Willow, or *Salix Russelliana*; and mixed with these, one plant of *Populus alba*, *P. tremula*, *P. fastigiata*, and *P. balsamifera*. Then the whole undergrowth might be a mass of Laurels, Privet, and Box; or walks might be made through it, and the following arranged in groups, so as to be very attractive, the last-named sorts being kept most to the outside.—Evergreen Oaks, a few Hollies, common Laurels, Portugal Laurels, Boxes of sorts, *Aucuba japonica*, *Daphne laureola*, *Arbutus unedo*, *Atriplex halimus*; *Rhododendrons*, if a little peat can be given them, and there is little or no calcareous matter in the soil; *Hypericum calycinum*, or *St. John's Wort*, and *Laurustinus*, keeping the latter chiefly at the outside. 2nd, if the Willows and Poplars should be too light, you may mingle with them a few Pines, as Spruce Firs, (*Abies excelsa*), *Picea pectinata*, and *Pinus austriaca*, and rigid; but if these are encouraged to feather to the ground, nothing else must be planted near them. 3rd, the Spruce Fir, and *Pinus austriaca* and rigid, would flourish pretty well in such a place, and would soon form a thicket of themselves; but if the place were desired to look well from the house, and to be a place of resort as well, then if such sombre trees were planted from 30 to 40 feet apart, walks could be carried through the space, and the above evergreens thrown into groups in the open spaces, to which might be added such deciduous plants as Privet, Dogwood, &c. 4th, if the surroundings admit of it, and as economy is your object, we would plant with Willows and Poplars, say from 30 to 40 feet apart, including a few Spruce, and then use Laurels for undergrowth, with a belt of *Laurustinus* for the outside.

NAMES OF PLANTS (*H. T. W.*).—No. 1 and 2, doubtful; specimens sent insufficient—1, *Gymnogramma Mertensii* (?); 2, *G. ochracea* (?); 3, *Alloxorus Polleus rotundifolia*; 4, *Doodia caudata*. (*N. W.*)—*Theca chinensis*, var. *Bohea*. (*J. D.*)—We cannot name seeds at sight. 1, *Bathinia* (?); 2, *Olea*; 3, *Vicia* (?); 4, *Hibiscus*. (*W. B.*)—1, *Doodia caudata*; 2, *Onychium japonicum*; 3, *Aspidium molle* (?); 4, *Mohria thurifraga*; 5, *Phymatodes peltata*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending February 17th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE ROUP.

HUNTING after some new breeds and varieties, I passed through Germany last summer, and went to a poultry establishment belonging to a nobleman. In the course of conver-

sation I complained of that bane of the poultry-yard, the roup, causing so much heartache to us poultry fanciers in England. The overseer laughed. "Roup! We know nothing about such wholesale destruction as you complain of. Roup! Your fowls eat their excrements, that is the most likely cause of it." This idea was new to me. I told him that I had my fowl-houses swept three times a-week thoroughly. "Not enough." "Shall I have it done once a-day?" "No, twice or thrice

a-day—as often as you feed them, and always before you feed them. Those fowls, chiefly, that receive grain will be attacked with roup unless the house, or at least the place on which the grain is thrown, be as thoroughly swept and cleaned as if you polished a looking-glass; otherwise grain may mix with their excrements and the mischief will be done, however little they may pick up with their food. It will be well to sweep the whole house every time, for, when hungry, your birds may begin to pick from the excrements any particle of food not thoroughly digested which may be found in these.”

I repeat the above as I heard it. I have tried the system, and it has answered. During the autumn my poultry yard remained free from the complaint; but, when in December I went on a journey, I saw, when returning, three hens suffering from the roup, and was informed that the person who had taken care of my birds during my absence had “taken it easy,” and frequently deviated from my instructions. I cured two of the sufferers, that had been only slightly attacked, according to the subjoined receipt, which I owe to the same overseer; the third died, its illness having been already far advanced.

He said, “If any of your fowls becomes ill, separate it immediately from the others, and place it in a run, the bottom of which consists of fresh turf. In wet or cold weather take a cage with turf in-doors. The fowl will recover in three or four days, unless the illness has been too long neglected. The roosting upon grass has in all cases the most beneficial effect.”

“A most pernicious effect upon the health of fowls,” he continued, “is produced by rich feeding after their having been on a long journey. Give them nothing by which they may satisfy their blind hunger too fast, no flour, no hard grain, only cut chicken-groats or a small quantity of crushed oats, but, above all, very, very little water on the first day.”—FRANCIS BROEMEL.

TESTING PURCHASED EGGS.

As you are now commencing the insertion of advertisements of eggs for sitting, will you allow me to advise those who purchase them to subject them to the water test before placing them under the hens?

Last season, wishing to have some new blood in my yard, I ordered eggs from an advertiser in your paper: some at £1 1s. per sitting, and others at a lower price. Not one of the highest-priced sitting hatched, although other eggs placed under the same birds did. Upon complaining to the advertiser, others were forwarded; but having my suspicions aroused, they were tried, and found to have been already sat upon, some having chickens in them, others being rotten; so I was saved the disappointment and annoyance of losing the hen's time, but did not think it would be of any avail to make another complaint.

If you insert this notice in your columns you may save others the vexations which always attend the unsuccessful sitting of hens.—A CONSTANT SUBSCRIBER.

[If our correspondent had sent us the name of the vendor of the eggs we would have published it.—EDS.]

WHICH IS THE BEST FOWL FOR THE TABLE?

ARE the Brahma Pootras good birds for the table? Since Dixon's Work (1857) I have seen no comment on degrees of quality of table fowls, which, whilst fit for show-purposes in their class, still may be very useful for the spit, when a defect would preclude their use for aught else. A Game bird is A1; Dorking is A2; but a black-boned Indian fowl (very rare?) for roasting, beats all in my opinion.

Pray give your opinion as to the comparative merits of Brahma Pootras as table fowls, in juxtaposition with their confères.—PETERBOROUGH.

[The “Fowl of Fowls” for the table is the Dorking. Not only is its meat of marvellous quality, but it has the property of contributing more choice and less coarse meat than any other bird that we know of at present. It has more breast, and its thighs are delicate. The backbone of a well-fattened young Dorking is said to be the perfection of poultry food. It is hard to say which is the second, as opinions differ so much; our own is, that a young Game pullet is A2, but she must be killed in proper condition—i.e., she must not exceed sixteen weeks old; she must have run wild ever since she left her mother; and she must have been dead two days when she is

eaten. The amount of breast on such an one is wonderful; the meat is sweet and high-flavoured, and the only fault ever found is that there is not enough of it. The Spanish chicken is very delicate, and the meat is finer in the grain than any other we know. The Hamburg is also very good. We should put Spanish A3. Two noted breeds are the Cochin-China and the Brahma Pootra, both most useful; but in our opinion the latter the more so. As table fowls they are coarse, and have far too much offal meat about them. They are as a Leicester sheep compared to a nine-stone Southdown. The black-boned Indian fowl mentioned is the filthiest thing to look at as food that we have ever seen. It is by no means rare, being the Silky fowl. It has blue flesh and nearly black bones, and however good the flavour may be (we have many of them, but have never tasted one), we should consider the look so repulsive, that nothing short of starvation would make us eat it.

There are of late two French fowls introduced, both of excellent table quality, the La Flèche and the Crève Cœur. They are high-class birds, but they are not so hardy as the Brahma. They are better birds for the table. The table you ask for should stand thus in our opinion. We class them on their food merits, without reference to their delicacy or strength of constitution:—

- | | |
|----------------|-------------------|
| 1.—Dorking. | 5.—Spanish. |
| 2.—Game. | 6.—Hamburg. |
| 3.—La Flèche. | 7.—Brahma Pootra. |
| 4.—Crève Cœur. | 8.—Malay.] |

GAME BANTAMS.

HAVING read the interesting notes on Bingley Hall Show by our esteemed correspondent “WILTSHIRE RECTOR,” and also the letter of “GALLUS,” with “WILTSHIRE RECTOR'S” reply to it, in “our Journal” of January 30th, relating to these universal favourites, I beg to offer a few remarks on the subject.

Of the four principal varieties of Game Bantams, my experience teaches me that the Black-breasted Reds are the easiest to breed true to feather; next to them, perhaps, Piles; then Duckwings, and lastly Brown Reds; and of these last there is hardly a first-class pen to be seen at any of our shows. Indeed there is still much room for improvement in each of the varieties; and, as “GALLUS” truly remarks, “He may consider himself indeed a lucky fellow who can obtain one good bird from a hatch.” Now “WILTSHIRE RECTOR'S” reply is certainly open enough. I only wish he had not given up Game Bantams, and then he might have agreed with us who find it difficult to reach the higher standard which we now aim at. If he judges the birds he speaks of having seen at his friends' by a comparison with the best birds of some three or four years ago, they might easily be considered all good birds. It is certainly not easy to breed such birds as the Black Red winners at some of our recent shows, and they are very easy to distinguish from the so-called “Game” Bantams that come in flocks to every poultry show. Undoubtedly five-sixths of these birds would be better killed than kept.

With regard to profit I can confidently recommend Game Bantams as being equal to Blacks for producing eggs, both as to number and quality. During the last two years I have never been for a single week without new-laid eggs from my Game Bantams; and the birds when fed up, though small, are as delicious for eating as any variety of fowl. In one sense they are, as “WILTSHIRE RECTOR” says, easy to breed, for, unlike the Sebrights, nearly all their eggs are fertile, and with proper care the chickens are not more liable to death than many other varieties; and last, but not least, it is probable that the most perfect specimens will continue to command as high prices as have ever been paid for them. They are steadily gaining ground, and with “GALLUS” I sincerely hope that they may long continue to hold the high position which they have so justly gained.—W. F. E.

NAMES OF FOWLS.

Wrong names are sometimes given to poultry, and, even if corrected, people persist in using them, because they are adopted in the schedules of prizes of poultry shows. The French fowl “Padoue,” *alias* “Poland,” is named Poland. So far well—the difference is trifling, but the name, so frequently used, “Polish fowls,” is decidedly absurd. They have as little to do with Poland and Polish poultry as Whitechapel with Cochin-China in Eastern Asia. Why another class of

fowls are called Hamburgs is a riddle to me. I lived fifteen years in Hamburg, and neither in that town nor in the surrounding country are fowls of this kind bred. They were quite unknown in that part of Germany up to 1859.

"Brunnen Pigeons" is another misnomer. The correct name is "Brünn Pigeons," from the town of Brünn, capital of the Austrian province of Moravia. The German word "brünn" means "a well." The Poultry Club has certainly enough authority to fix the names of poultry, at least in truth to geography and nationality.—F. B.

"WILTSHIRE RECTOR'S" GRIEVANCE.

Do not think the above a sensational heading. It is in a certain sense—a poultry sense—true. Shows as a rule take place in winter, and as a rule I wish it were rescinded, only in the midland and northern parts of England. Well, these things being so, I am debarred the pleasure of being present at the majority of these charming exhibitions. I like to be at shows, and I like to have my say afterwards. I like to notice where little improvements may be made; and I like to be counsel for the birds, and look after their interests. But how can I in winter travel so far, living as I do in Wiltshire? If I attempted to go to the distant shows there would be a domestic mutiny, perhaps even I should be locked up in my study. But to show that I have a real grievance I take up a Number of "our Journal," and read without alteration the "list of shows." First, Hanley, Staffordshire—too far off. Then Wentworth, Yorkshire—worse still. North British Columbian Society (Glasgow)—fancy going to Glasgow for pleasure in December! Then comes Heckmondwike—queer name that, I wish I knew its derivation. My "Clergy List" tells me it is in York-shire. York-shire again! Sensible people live there, surely. Then, next Manchester, where it is said always to rain. Fancy facing snake and drizzle after a journey of nearly two hundred miles! Then comes the Paisley Show—worse still. Then Fife and Kinross. I should like once more to see Kirkcaldy, but—the distance. Aberdeen—well, the granite city and I are old friends, but no renewal of intercourse, please, in midwinter. Next the show at Skye—no, my eye is wrong; it is at Dumfries and Maxwelltown, the braes of which latter place we know are bonnie in summer and autumn, but not later. But what do I read next? Cork and South of Ireland. Fancy crossing the sea in a recent gale! It would have been no gala day to me. Then West Cumberland and North of England—why not South of England? I read then Walsall, Je-Burgh, Kendal, and lastly of the Show at Nantwich.

It is clearly impossible for me to be present at any one of these shows. Have I not, then, a grievance? I am, in fact, reduced to Bath and West of England when not held in Cornwall, and a very few small shows near me. By a tremendous effort and screwing-up of courage I went last year to Birmingham, but that was an exceptional case. I heard a whisper of a show to be held at Cheltenham, but the whisper has died out. I know of several friends who would exhibit there, but Cheltenham makes no sign. On the Great Western there surely might be a show or two. Why not one at Windsor? The king of Light Brahmas lives near—Mr. Pares. Then the pens could be hired, as was the case at Calce, from Devizes, which is on the same line of railway, and London fanciers would be sure to send their birds. There is also Swindon, easy of access, and abounding with fowl-loving mechanics. Or there's Reading. Or, again, why not have a show at Oxford? Numbers of the undergraduates would attend.

I hope this appeal will meet with a response. I do not myself exhibit, because my sense of fairness as a writer will not allow me to do so; but I will try and induce all my poultry friends to send to such show or shows, and shall be delighted to attend and record my impressions. It is too bad that the northern should have all the pleasure to themselves. I am jealous, and feel myself a badly treated Wiltshire Rector.

P.S.—Whenever there is a poultry show I plead that there be a Pigeon show as well.

EGGS HATCHING AFTER BEING CHILLED.—Some of your readers may be interested to know the following circumstances:—I set a White Cochins-China hen upon eleven eggs on the 9th ult.; she had been sitting eight days, when, by accident, she was shut off from her nest the whole of one night, upwards of twelve hours. On the 21st, she hatched eleven chickens.—H. J. Lucas, *The Rectory, Edith Weston.*

ROCHDALE POULTRY SHOW.

Your correspondent in the Journal of February 6th, gives such a favourable account of the Poultry Club's National Show, that those who were not lucky enough to be present, would naturally suppose that the Show was a great success. My impressions were not so favourable. The room was calculated to hold about five hundred pens of birds, whilst about one thousand were attempted to be exhibited. I say "attempted," because when one class is shown in as many as three different parts of the room, fair judgment seems hardly likely to be attained. Some exhibitors found their birds so unfavourably placed (owing to the overcrowded state of the place), that they were not surprised their birds were not noticed in the prize list, although they were breeders of many years standing, and certainly ought to know what birds should be considered up to the mark. Complaints of unfair treatment of Pigeons have been sent to you. What steps have the Poultry Club taken to discover the perpetrators of this outrage? If the Poultry Club make themselves responsible for another show, it is to be hoped they will take care to have room enough for the fair arrangement of all the classes, and provide servants who can handle Pigeons without mutilating their feathers. There is only one feature in the Show which is at all to be commended—viz., making the pen consist in all classes of one bird of each sex.—AUDI ALTIAM PARTEM.

JUDGES AND JUDGING IN SCOTLAND.

Now that poultry shows are over for the season, allow me to make a few remarks on the above subject. Some time ago I asked an old exhibitor if he was going to show at Paisley. "No," he said, "I have been once too often there." Well, I did not think anything unfair would be done; so I entered a few pens, and sent them in due course—the very best I had; and those who happen to know my birds would speak of their merits in no disparaging manner, I think. After the show I received my birds and a catalogue, and found that I had not obtained a single notice. I thought I would see who had been judging, when I found such a host of names, that one would have thought they ought to have judged properly. To complete my surprise, I found that a pen which I had just sold, and which exhibited nothing like the size of markings or the quality of the birds which I had sent, had won a prize.

I may mention another Show (Jedburgh), at which the decisions perfectly astounded some old and experienced exhibitors from England; and I may also name that at Kelso. Some birds arrived too late for competition; but a gentleman on the spot ascertained what position one pen that arrived late would have held in the prize list provided it had been in time, when he was informed that it would have taken no position at all; for, said the gentleman writing (and I have his letter before me now), he (the Judge) prefers small-spotted, light hens before large spangled ones. If such is the opinion of any "Judge" of Hamburgs, the sooner he takes a look through all the principal Shows in England the better; and he should also obtain a copy of the "Standard of Excellence," that he may be better qualified next time he goes from home.

I write with all kindly feeling towards the Scotch fanciers, but my name for one will not appear in their catalogues again unless I hear of some better Judges being appointed. I am now like my friend, I have been once too often north, unless the change alluded to be made. If the Committees are not acquainted with good and experienced Judges, let them ask you or the Poultry Club, and I am sure you will give them every information in your power.—Justice.

VULTURE HOCKS.

The letter of "Y. B. A. Z." on this subject deserves the most careful attention of all Brahma breeders. That there is a strong and growing objection abroad against any approach to the profuse feathering at the hock is very obvious. Though not a dealer, I have frequent applications for my birds, and almost every letter that I receive contains this strict injunction "Be sure not to send any that are vulture-hocked!" One correspondent, who has been a very successful exhibitor, actually remarked "A bird cannot be a true Brahma if it has the vulture hock!" If this objection be allowed to remain, and to sway the decision of judges at our poultry shows, then farewell

to the finest and most admired specimens of this rising breed.

I have recently visited the yards of some eminent Brahma breeders, where in former days I have seen some of the finest specimens of this class that were ever exhibited. Such size, colour, symmetry, abounding fluff, and withal legs remarkably short and profusely feathered, that amateurs like myself came from afar to see them, and their fame rang over the country. Great pains were taken, I know, that all the birds reared in these yards should be after this particular type. Had a cockerel then appeared with an exposed hock joint, and a scantily feathered leg, I knew his fate; he would have been summarily delivered over to the hand that holds the knife. Conceive my surprise in my late visits, at finding that in consequence of the strong prejudice against vulture-hocked Brahmas that has recently sprung up, nearly the whole of the magnificent stock in each yard had disappeared. A few poor cockerels remained in one place, like the last remnant of a once noble and illustrious family whom the hard hand of misfortune has struck down in the world, and I observed that they were in close confinement, evidently under capital law.

In their walks I saw another race moving about, looking very ragged about the legs, which to my eye appeared provokingly long, and as to the hock joint, instead of being gracefully begirt with feather, it was quite bare and rudely exposed, making the birds look exceedingly ugly, wretched, and beggarly.

I inquired for some of the splendid stock that I had seen before, and found that one was sold for a mere trifle, a second was given to a lady to run with some common hens, and a third, *horribile dictu*, was drawing near to his end, his death-warrant was signed. He was vulture-hocked! This was really a magnificent bird. I felt like the good, honest fellow who has the charge of the poultry, very sorry for it. Poor old John was almost in tears. "You cannot think Sir," he said, "how much it has put me about." "My master has a mind, I know, for them vulture-hocked, and he hates the sight of the new sort, but he says as how it's like this. You see it's the law, and he can't help it." "Well, Sir, it's a great pity, and master will be sorry enough for it by-and-by, that he will, and it will just sarve him right."

Some may be curious to know if the hock feathers of this bird that was doomed to die were long and stiffly set. By no means, they were rather soft, and curving about three parts of an inch.

With anxious concern I inquire, Must all the pains that have been taken, and the expense that has been incurred in bringing our birds to such high perfection, be set utterly at naught, simply because a new whim has possessed the brain of some "able judge, or judges?"

But may not this dire evil be averted? I feel confident that it may. I do not suspect that more than one or two of our able judges are thus prejudiced, and if a few of our most celebrated breeders would avail themselves of the open columns of this Journal to express their views upon the matter, I doubt not that the silly prejudice which has gone abroad would be arrested, and shivered and scattered to the winds. If, however, it be left to just two or three to wield their pen in defence of the true and the right, depend upon it nothing will be done. *Tac populi* will command the attention of the judge or the judges who have occasioned this grievance, and I have too much respect for their good sense to imagine for one moment that they will persist in setting our wishes at defiance.—*JUS ITI*A.

EXPENSES AND RETURN OF POULTRY KEEPING.

AT page 118 "C. E." solicits suggestions upon this subject. Now, in the first place, the statement shows the total number of birds fed in the year to be 5875 = per week 113, and surely there must be some error in these figures, for the food expenses appear to be very much too little for the large number, and too large for the small number. The error appears to me to have occurred by not having divided the total 5875 by 12 (as each month's stock for the twelve months is separately stated); this would give an average of about 489 birds always on hand, and a number more likely to be maintained at the cost named. Are we to understand the £8 7s. 6d. is only for stock bought?—and does it include the value of the stock in hand at the commencement of the year?—and, as the wickerwork and pans no doubt are still in use, they should be brought to the credit of profits for whatever they may be worth. I am sure, from

my own experience with keeping poultry, that this, if we may so call it, balance sheet, does not fairly represent what are the real profits upon such a large stock, more especially if we have to add the charge of 1s. per day for labour; for that would then add £15 to the expenses of the year, and show a positive loss of £9, which, I am sure, was not "C. E.'s." intention. I have often proved, by accurate accounts, that with poultry kept either on a large or small scale, and properly managed, a profit of from 40 to 50 per cent. can be shown. I should like "C. E." to give us, what evidently was his intention, a statement that will show that poultry keeping is not only a pleasant pastime, but also a profitable one.—*CADBURY*.

CRYSTAL PALACE BIRD SHOW.

As regularly as the earth revolves on its axis, so do our national shows come round; among which, and of no small importance, is that of British and Foreign Birds at the Crystal Palace, which commenced on Saturday last. We have watched with interest the gradual development of this annual Show, and we have no hesitation in saying that it has reached a degree of perfection unequalled by any of its class. The present display is pronounced by the Judges to be unsurpassed by any of its predecessors, and such an one has never before been witnessed. We do not envy the Judges the onerous task which they must have had to award the prizes to such a collection.

The birds, with a few exceptions, are in magnificent plumage and condition, and prove with what care the respective owners must have attended them. Among the British birds some very splendid specimens are noticeable of the Bullfinch and Goldfinch. The Robin, Blackbird, and Thrush have praiseworthy representatives. In the varieties of British birds are a curiously pied Lark and a pied Linnet. The Warbler class has representatives in fine specimens of our beautiful little songster—the Nightingale.

There is a goodly group of Foreign birds, among which are some fine Grey and other Parrots. All the known varieties of the Waxbills may be seen at this Show, as also several Java Sparrows, Virginian Nightingales, and Cardinals in unrivalled plumage.

With reference to the Canaries, the Norwich class is very good, but the Belgians are not so numerous as formerly, nor are they quite up to the standard with respect to beauty of form and condition. The Lizards are numerous and fine. The class of Jonque Goldfinch Mules is very superb, and several groups of Canaries in cages containing six of each class must be seen in order to have any adequate idea of their beauty.

The management deserves the greatest praise for the excellent manner in which the exhibition is arranged and carried out.

CANARIES.

NORWICH (Clear Yellow).—First and Extra Prize, G. Y. Collinson, Thorp Hamlet, Norwich. Second and Third, J. Pullen, Shore-ditch. Very Highly Commended, F. Willis, St. Martin's-at-Oak, Norwich; J. Pullen. Highly Commended, F. Willis; W. Walter, Winchester; G. Y. Collinson; J. Pullen; J. Judd, Newington Butts. Commended, F. E. Colman, Clapham Common; T. Newmarch, Old Street Road, St. Luke's; J. Judd; R. Mackley, St. Mary's, Norwich; O. Lipscombe, West-bourne Grove, Bayswater. (A very superior class.)

NORWICH (Clear Buff).—First, G. Y. Collinson. Second, F. Willis, Third, J. Pullen. Very Highly Commended, F. Willis; G. Y. Collinson; J. Pullen. Highly Commended, W. Walter; J. Judd. Commended, C. J. Ayre; W. Walter; O. Lipscombe. (A first-rate class.)

NORWICH (Variegated or Marked Yellow).—First and Second, G. Y. Collinson. Extra Prize, G. J. Barnesby, Derby. Very Highly Commended, F. Willis; G. Y. Collinson. Highly Commended, G. Y. Collinson; W. Walters. Commended, S. Tomes, Southampton; G. E. W. Rawlinson, Gloucester; W. Walter; J. Judd; R. Mackley; O. Lipscombe.

NORWICH (Variegated or Marked Buff).—First, T. Banfather, Norwich. Second, F. Willis. Very Highly Commended, G. Y. Collinson; W. Walter; J. Judd. Highly Commended, G. Y. Collinson; W. Walter; T. Newmarch.

NORWICH (Crested, or any other variety).—First and Second, G. Y. Collinson. Very Highly Commended, W. Walter. Highly Commended, T. Banfather. Commended, S. Tomes; J. Judd.

BELGIAN (Clear Yellow).—First, W. Phillips, Old Basford, Notts. Second, T. Roper, Lambeth. Third, T. Smith. Very Highly Commended, J. Rutter, Sunderland; T. Roper; O. Nicholson; J. Judd. Highly Commended, H. Marshall, Durham; J. Rutter. Commended, H. Marshall; J. Rutter; J. Grimani. (A good class.)

BELGIAN (Clear Buff).—First, W. Phillips. Second, J. Doel, Flynmonth. Extra Prize, W. Vic, Derby. Very Highly Commended, J. Rutter; L. Corti, Bath Street, City Road; J. Judd; W. Phillips. Highly Commended, L. Corti; J. Doel; A. Dalton; T. Roper. Commended, L. Corti.

BELGIAN (Variegated, or Marked Yellow).—First, O. Nicholson. Second, J. Rutter. Commended, T. Roper.

BELGIAN (Variegated, or Marked Buff).—First, A. Roper. Second, T. Roper. Very Highly Commended, H. Marshall; W. Phillips.

BELGIAN (Crested, or any other variety).—First, H. Ashton, Prestwich. Second, W. Walter. Very Highly Commended, G. J. Barnesby. Highly Commended, T. Newmarch; W. Williams; W. Walter. Commended, T. Newmarch; J. E. Linn, Crystal Palace.

LONDON FANCY (Jonque).—First, J. Waller, Tabernacle Walk, Finsbury. Second, J. Judd. Highly Commended, J. Waller. Commended, J. Judd.

LONDON FANCY (Mealy).—First, J. Waller. Second, J. Judd. Highly Commended, J. Waller; J. Judd. Commended, J. Waller.

GERMAN, OR ANY OTHER VARIETY EXCEPT NORWICH OR BELGIAN.—First, W. Walter (German). Second, W. Barnes, Cannon Street, E.C. Extra Prize, S. Tomes (Jonque, Variegated Cinnamon). Highly Commended, W. Barnes; W. Walter. Commended, T. Newmarch; J. Pullen.

LIZARD (Golden-spangled).—First, G. Harrison, Canterbury. Second, J. Waller. Extra Prize, W. Williams, Nottingham. Very Highly Commended, G. Harrison; J. Waller; W. Williams. Highly Commended, L. Corti; J. Waller. Commended, H. Ashton; Rev. V. Ward; H. Winfield, Horselydown; J. Pullen.

LIZARD (Silver-spangled).—First, G. Harrison. Second, J. Tarr, Thornhill Place, Caledonian Road. Extra Prize, W. Williams. Very Highly Commended, F. W. Fairbairn, Canterbury; G. Harrison. Highly Commended, G. Harrison; J. Tarr; P. Flexney, Caledonian Road; T. Newmarch; J. Waller. Commended, Rev. V. Ward, Canterbury. (Very good class.)

JONQUE CINNAMON.—First, J. Wynn, Northampton. Second, G. Y. Collinson. Very Highly Commended, S. Tomes; G. Y. Collinson. Highly Commended, H. Marshall. Commended, J. Wynn; W. Gamble, Northampton; J. Waller; C. T. Ayle, Sunderland. (A very superior class.)

BEFF CINNAMON.—First, J. Waller. Second, W. Walter. Very Highly Commended, J. Wynn. Highly Commended, W. Gamble. (A good class.)

STEEL *Jonque Goldfinch*.—First, H. Ashton. Second, J. Doel. Extra Prize, H. Marshall. Very Highly Commended, H. Marshall; J. Doel; W. H. Moore, Plymouth. Highly Commended, H. Marshall; H. Ashton. Commended, J. Baum. (A first-rate class.)

MULE *Mealy Goldfinch*.—First and Second, H. Marshall. Extra Prize, J. Judd. Very Highly Commended, F. E. Colman; J. Doel. Highly Commended, G. Harrison. Commended, J. Judd; R. Mackley.

MULE (Any other variety).—Prize, H. Marshall. Extra Prize, O. Nicholson. Very Highly Commended, G. Moore, Havlock Terrace, Northampton; H. Ashton; W. Barnes; J. Judd. Highly Commended, W. Gamble; F. E. Colman.

SIX NORWICH IN ONE CAGE.—First and Third, G. Y. Collinson. Second, J. Judd. Very Highly Commended, W. Walter; G. Y. Collinson. Highly Commended, J. Grimani; T. Newmarch; J. Judd; R. Mackley. Commended, W. Walter; G. Harrison; T. Newmarch.

SIX BELGIANS IN ONE CAGE.—First, T. Boper. Second, J. Doel. Third, J. Judd. Very Highly Commended, J. Judd. Commended, A. Isaacs, Prince's Street, Leicester Square; T. Newmarch.

SIX GOLDEN-SPANGLED LIZARD IN ONE CAGE.—First, F. W. Fairbairn. Second, T. Newmarch. Third, G. Harrison.

SIX GOLDFINCH MULES IN ONE CAGE.—First, H. Ashton. Second, W. Walter. Third, J. Doel. Very Highly Commended, J. Judd. Highly Commended, J. Doel. Commended, W. L. Chapman.

BRITISH BIRDS.

BELLFINCH.—Prize, H. Vine, Castle Street, East Cowes. Equal, W. Gamble. Very Highly Commended, T. Newmarch; C. Carver. Highly Commended, G. Moore; T. Newmarch; C. Carver; W. Walter.

CHAFFINCH.—Prize, J. Knibb, Northampton. Very Highly Commended, J. Palmer, Upper Newnham, Northampton. Highly Commended, H. Ashton.

GOLDFINCH.—Prize, S. Hind, Beaumont Street, Manchester Square. Extra Prize, H. Vine. Very Highly Commended, J. Grimani; J. Judd; Capt. C. H. Fisher; J. Pullen. Highly Commended, J. Judd.

LINNET.—Prize, H. Marshall. Very Highly Commended, D. Carver. Commended, W. Walter.

SKYLARK.—Prize, J. Judd. Very Highly Commended, J. Judd; J. S. Benton, Rochester. Highly Commended, W. Walter; J. Pullen.

WOODLARK.—Prize, W. Walter. Very Highly Commended, J. Crew, Plumstead. Highly Commended, T. Newmarch.

ROBIN.—Prize, W. Miller. Very Highly Commended, T. Newmarch; J. Crew. Highly Commended, J. Crew. Commended, J. Palmer.

BLACKBIRD.—Prize, F. S. Vine. Extra Prize, W. Newman. Very Highly Commended, J. Knibb; G. W. Teasdale; D. Carver.

SONG THRUSH.—Prize, H. Vine.

STARLING.—Prize, H. Vine. Highly Commended, J. Judd.

MAGPIE.—Prize, W. Walter.

ANY OTHER VARIETY.—Prize, H. Marshall. Extra Second Prizes, T. Newmarch; O. Nicholson; J. Kennard. Very Highly Commended, J. H. Elliott, Sydenham Hill. Highly Commended, J. Pullen; J. Palmer.

BIRDS OF PASSAGE AND MIGRATORY BIRDS.

NIGHTINGALE.—Prize, W. Hawtrey. Extra Prize, H. Johnson. Highly Commended, Miss H. Maunder, Finner, Middlesex; C. F. Johnson, Blackfriars Road.

SISKIN OF AERDEVINE.—Prize, J. Judd. Very Highly Commended, W. Walter; H. Ashton. Highly Commended, J. Judd.

TITLARK OF TREE PIT.—Prize, J. Pullen.

ANY OTHER VARIETY.—Prize, L. Fraser.

FOREIGN BIRDS.

COCKATOO (Lemon or Orange-crested).—First, G. Boswell. Second, M. George. Commended, T. Newmarch.

COCKATOO (Lead-beater or Rose-breasted).—First, J. Judd. Second, A. Isaacs. Very Highly Commended, A. Isaacs; Mrs. M. Williams.

PARROTS (Any other variety).—Prize, J. Baum.

PARROTS (Grey).—First, J. Judd. Second, A. Isaacs. Very Highly Commended, W. Walter; W. Eadlings, Dalston. Highly Commended, W. Wichelow, Mile End Road; F. Woodgate, Norwood.

PARROTS (Green, or any other variety except Grey).—First, J. Baum. Second, W. Westbrook. Third, F. G. Dutton. Very Highly Commended, J. Judd. Highly Commended, A. Isaacs; J. Baum. Commended, A. Isaacs; A. W. Booker, Liverpool.

LOVE BIRDS.—Prize, J. Judd. Extra Prize, G. Billett. Very Highly Commended, T. Newmarch. Highly Commended, W. Walter.

AUSTRALIAN GRASS PARAKEETS.—Prize, Mrs. H. White. Extra Prize, W. Walter. Very Highly Commended, T. Newmarch; Mrs. H. White, Hyde Park; J. Judd. Highly Commended, T. Newmarch; A. Isaacs.

PARAKEETS (Ring-necked or Diamond).—Prize, F. G. Dutton. Very Highly Commended, W. Williams. Highly Commended, J. Baum.

PARAKEETS (Any other Variety).—Prize, A. Isaacs (Turquoise). Very Highly Commended, Rev. A. Johnson (Stanley).

PARROTS (King's).—Prize, A. W. Booker. Very Highly Commended, A. Isaacs.

PARAKEETS (Roschilly).—Prize, J. Baum. Commended, J. Judd.

PARAKEETS (Pendant's).—Prize, J. Baum.

COCKATEALS.—Prize, J. Judd. Very Highly Commended, J. Baum.

LORY (Any Variety).—Prize, A. Isaacs.

SPARROWS (Diamond).—Prize, J. Judd.

SPARROWS (Coral-necked).—Prize, J. Baum.

SPARROWS (Javal).—Prize, H. Vine. Extra Prize, W. Walter. Extra Prize, J. Judd. Very Highly Commended, T. Newmarch; J. Judd. Highly Commended, W. Williams; J. Judd.

NONPARFELS.—Prize, C. T. Bell.

INDIGO BLUE BIRDS.—Prize, J. Judd.

BISHOP BIRDS.—Prize, J. Judd.

WAXBILLS (Zebra).—Prize, Mrs. La Touche. Extra Prize, J. Baum. Very Highly Commended, Rev. A. Johnson. Highly Commended, J. Baum.

WAXBILLS (Orange-checked).—Prize, J. Judd. Highly Commended, J. Judd.

WAXBILLS (Any other Variety).—First, W. Walter. Second, J. Judd. Third, J. Baum. Very Highly Commended, J. Baum. Highly Commended, G. Billett, Southampton; Miss H. C. Brown, Forest Hill; J. Baum.

NIGHTINGALES (Virginian).—First, G. Billett. Second, T. Newmarch. Third, Mrs. H. White. Very Highly Commended, T. Newmarch; Mrs. La Touche, Upper Brooke Street. Commended, T. Newmarch.

CARDINALS.—Prize, J. Baum. Very Highly Commended, J. Baum. Highly Commended, G. Billett.

WHITISH BIRDS.—Prize, G. Billett. Commended, J. Baum.

PRING CROWS OF AUSTRALIA.—Prize and Highly Commended, L. Fraser, Knightbridge.

FIRE FINCHES.—Prize, J. Baum.

ANY OTHER VARIETY.—First, T. Newmarch (Brazilian Finch). Second, J. Baum (Saffron Finch). Third, W. Walter (Madagascar). Very Highly Commended, Mrs. La Touche; J. Judd; L. Fraser. Commended, L. Cousens; J. Judd.

PHEASANTS (Gold and Silver).—First and Second, L. Fraser.

PHEASANTS (Any other variety).—First and Second, M. Leno. Chinese Ring-necked and White Pheasants.

JUDGES.—*Composers*.—Mr. T. Moore and Mr. A. Wilmore. *British and Foreign Birds, and Pheasants*.—Mr. W. Goodwin.

HIVES—BEES' NIGHT EXCURSIONS.

BEFORE swarming-time, I had two Woodbury bar-and-frame hives, made of straw, on wooden frames, by our basket-maker, who, though not a live-maker, had made me some of Payne's cottage hives (two or three years previously). I gave him my notions of how he should set about making them. However, he did not take my hints; and although the hives could be used, they did not suit me, for the corners were far from square at the bottom, indeed more than an inch intervened in some places between the frames and sides of the hives, so that I hardly thought of having any more made. However, after reading "M. D.'s" various communications on what he calls his "native hive," which seems to me to be exactly like mine, I thought I would have another trial this winter, and was determined that my own ideas of the mode of manufacture should be carried out; and as these hives have turned out to be greatly superior to those made before, I trust some details may be of use to some of our bee-keeping friends.

Have a frame made of wood fully 1 inch thick, exactly like the top of a Woodbury hive, and 2 inches deep, dovetailed and pined. Let the bottom edge be made somewhat concave, so that the round band of straw, when sewn to it, will fit into the concavity. Have quarter-inch holes bored about half an inch above this edge, and straight through the wood all round for the stitches to pass through, and about 1 1/2 inch apart. Then take a flat piece of wood, somewhat larger than the frame, place your frame on it, with the lower edge upwards; have four pieces of quarter-inch iron wire as straight as you can select, and about 15 or 16 inches long, square-pointed at one end; and drive one of these wires into the board close within each corner of the frame (this is not well represented in the engraving), and perfectly upright. Next make five laths of wood, boring quarter-inch holes at the end of each lath at proper distances, to hold the top ends of the wires apart; four of these laths go from wire to wire all round, and the fifth is made to go diagonally across. These laths will hold the wires rigid, and in this frame the hive is made. The wires keep the straw in its proper place, and allow it to be pulled sharply round them, so as to obtain a good square corner; the straw requires to be beaten a little at the corners to bring it into good shape at each turn. With this contrivance, a young man who tried to make a common hive, and produced a very sorry article, has made me three good square straw hives, fit to look at; indeed, little or no skill is required, excepting the keeping the band of straw of a proper thickness, for the wires make capital guides, and bear pulling at, so as to make the stitching very firm. The ring used to keep the straw of a proper thickness is a section of a cow's horn, about 2 inches long; this being slightly conical, is much better than a simple iron ring.

Almost any one, with a little patience, may by adopting the above plan make very good square Woodbury hives; and if the

bar hives are wanted, the holes in the laths may be a little closer together, so as to have the hive somewhat less at the bottom than at the top. This will facilitate the taking out of the combs, and also prevent any risk of their falling, if accidentally separated from the bars, the hive being like the Grecian, somewhat conical, only square instead of round.

So much for hives. Now for uniting bees. I have united bees many times, and have succeeded well; however, to my cost, I find that if you unite bees to a hive having a super on it in which there are bees and combs, a civil war will be the consequence; therefore, I say, never unite fresh bees to a hive having a super on it, or being in two or more compartments.

On more than one occasion I have heard great commotions in some of my hives late at night, when it has been only starlight: there being no moon above the horizon, and several bees have taken flight whilst I have been listening, but I never could make out the reason for it. Could it have been queen encasements? I find one such occasion in my note book on the 1st of May, 1862.—C. F. GEORGE.

MR. LANGSTROTH, THE INVENTOR OF FRAME HIVES.

FOUL BROOD IN CALIFORNIA AND THE ATLANTIC STATES.

It may be remembered, that in THE JOURNAL OF HORTICULTURE of January 24th, 1865, I expressed the opinion that Mr. Woodbury had unintentionally failed to do me justice with respect to my indebtedness to the German apiarian. Having recently read with care all the back Numbers of the Journal from 1859, I have now to thank him for his liberal appreciation of my apiarian labours, even when he supposed my hive to be only a modification of a German invention. If I needed any other evidence than this of Mr. Woodbury's intention to do me full justice, his manly and straightforward discussion of the subject of foul brood, under circumstances which would have prompted an unfair man to disingenuous courses, clearly shows him to be incapable of withholding proper credit from any one.

That Mr. Woodbury may have a more complete idea of the progress of my invention, I have sent him the first edition of my work on the "Hive and Honey Bee," published in the spring of 1853, and the second edition published in the spring of 1857. One of the most important features of my hive was invented and fully tested in 1850, and the whole thing was brought to such a state of completeness in 1851, that I applied for a patent in December of that year, which patent was issued in October, 1854. The frames of the Baron von Berlepsch are first mentioned in the "Bienenzeitung" (supplement to), November 5th, 1853, in which he claims to have had them in use since 1843, in a kind of hive which he calls his "Rahmenlutter (frame-ventilator). This hive he must have deemed of no practical value, or he would not, after his famous visit to Dzierzon in the disguise of a Bavarian peasant, have abandoned its use and recommended in the highest terms the Dzierzon hive. He does not say how these frames were made or used, but he certainly could not have considered them better than those which he subsequently introduced as an improvement on the Dzierzon hive; at any rate the public knew nothing of his prior invention, whatever it was.

It will be seen from these facts, that long before the Baron had announced his forthcoming hive, my own was both invented and patented, and the first edition of my work will further show that its essential features were there given, together with a very full explanation of the various processes by which I accomplished such important results in the practical and scientific management of bees. I may also add, that in 1852 a large number of my hives were publicly used by myself and others. That the Baron could not have copied from my invention, of which unquestionably he had not the slightest knowledge, will be evident, not only from his high character for honourable dealing, but from the widely different plan upon which he inserted his frames in the hive; some of the disadvantages of which plan I will venture now very briefly to describe:—

1. The Berlepsch hive opening on one side instead of the top, makes it impossible to examine or remove any frame without first loosening and removing all the frames between it and the side door. Having used hives with such an arrangement side by side with those opening at the top, I believe that at least three of the latter can, on an average, be opened and examined to one of the former.

2. The Berlepsch hive making no provision for adjusting

the distances between the frames at will, does not so readily as with mine allow the relative position of the frames in the same hive to be changed, or facilitate the free exchange of frames from hive to hive.

3. The Berlepsch hive by making the top bars of the frames too close-fitting to the case which contains them, and parts of both the top and bottom bars of the frames close-fitting to each other, causes them to be soon glued by the bees so fast to the case and each other as to interfere very seriously with their easy removal from the hive.

4. The Berlepsch hive making no provision for the removal of the surplus honey, except in frames taken from the main body of the hive, the purity of the honey is very often affected by being mixed with bee-bread, or being deposited in cells previously used for breeding-purposes.

In making these criticisms upon the hive of so distinguished a man, I have not the slightest desire to depreciate the eminent services which the Baron has rendered, by his writings, to the cause of practical and scientific bee-culture.

After Mr. Woodbury's woful experiences with foul brood, he will be glad to learn that a Pennsylvanian has discovered, as he thinks, a cheap and effectual cure for this pest of bee-keeping. If this remedy after the most thorough trial should prove efficacious, he will by communicating it to the public be able to confer upon bee-keepers a boon of priceless value, and we shall all be ready to hail him as the "Pennsylvanian Bee-Friend." In California, where bees were introduced only a few years ago, and where they found, as in Australia, a honey paradise, this terrible distemper has in many places nearly destroyed all pleasure and profit in their cultivation. Its ravages in the Atlantic States are increasing, as I frequently hear of its breaking out in places where, until recently, it was wholly unknown.—L. L. LANGSTROTH, *Orford, Ohio.*

[In thanking Mr. Langstroth for the very high compliment he has paid me, I can with truth assure him, that he does me no more than justice in believing me to be incapable of wilfully withholding from any man that credit which is fairly due to him. I am in receipt of the two early editions of his "Practical Treatise on the Hive and Honey Bee," to which he refers, and which fully bear out all that he has above stated with regard to the time at which he gave practical application to the principle of the frame hive, whilst I can most cordially endorse all that he advances with regard to the superiority of his hive over that of the Baron von Berlepsch.

I much regret to learn that that fell destroyer, foul brood, is ravaging the hitherto prosperous apiaries of California and the Atlantic States, and most sincerely do I trust that the remedy of the "Pennsylvanian Bee Friend" may turn out a "perfect cure," and that he will worthily deserve his title by making it public. Should he do so, I hope Mr. Langstroth will at once communicate it to "our Journal," and by so doing add another to the many obligations which, by his writings, he has already conferred on British apiarians.—A DEVONSHIRE BEE-KEEPER.]

A CURE FOR BEE DYSENTERY.

I CAN neither agree with those who imagine that dysentery is caused by a large consumption of food during the winter months, nor with those who think there is no cure for the malady, bad as it is. Last winter I placed two stocks with their entrances towards the north, and the two consumed only 12 lbs. of honey, yet they had dysentery very badly indeed. Its cause was dampness, occasioned by the rain finding its way through badly-made covers. I tried different remedies, but to no purpose. At last I resorted to the remedy referred to by Mr. Everest, and the result was a complete cure.

This winter I placed three stocks, all in Woodbury frame-hives, in a bee-house with a southern aspect: one of them was left unventilated, and the result was dysentery. Upon examination no one could doubt the cause, which was evident from the quantity of condensed vapour on the glass and mildew on the combs and on the sides of the box. Upon removing the floor-board I found hundreds of dead bees upon it, many of them lying in a pool of matter which had, doubtless, escaped from their bodies upon bursting. This was on the 17th ult. I immediately gave them a clean floor-board, and applied the remedy. I was unable to look at them for eight days, when I found the floor-board in a very dirty state, but only about a dozen dead bees upon it; there was, moreover, scarcely any wet dirt, nearly all being dry, and some days old. I gave them another clean floor-board, and upon examining them two days later I found but

one dead bee, and a few, I think eight, spots of dysenteric dirt. My bees, therefore, which about a fortnight ago were in the worst possible state from dysentery, are now as well as ever, and more lively than either of the other stocks in the same house.—Z. B.

We should be glad to receive information as to the nature and mode of application of the remedy you employed.

BEE FOUNTAINS.

In one of the old hand-books is the suggestion that a tumbler filled with water, and turned upside down upon a plate, is a convenient and cleanly mode of watering bees; but that the water soon becomes bad, and must be changed every day. It at once struck me that this frequent change is quite unnecessary, and that a fragment of pondweed, especially if rooted, would keep the water sweet for any length of time. The time of year was not very favourable for an experiment of the kind; nevertheless, in the middle of November, I filled a tumbler with spring water, put into it a slip of *Chara vulgaris* unrooted, and, reversing the glass upon a plate, placed it in a window, and left it to take its chance. After rather more than two months, during which the loss by evaporation has been once supplied, I find the plate covered over with a beautiful confervoid growth (which of course would allow of the larger weed being removed), and the water is as sweet as on the day it was put in. This must be a much neater and more cleanly arrangement than the shallow pan, in which not only much dirt accumulates, but the bodies of many bees, which are drowned from time to time notwithstanding the pebbles. If the supply of water from under the rim of the glass is not sufficient, it can be increased by inserting a bit of straw or shaving. The confervoid growth should be allowed to remain, unless it increase very fast. A propagating-glass would allow of a larger body of water, and so would not require to be filled so often; and if the plan really answers in practice, there are many ways of making the little apparatus pretty and ornamental by those who are so inclined.

In connection with this matter, is it quite certain that the idea current in the Isle of Wight and elsewhere that the bees go down to the sea twice a-day to drink, is purely fanciful, especially in connection with the fact of their crowding to manure water and other saline deposits? I ask because in October last, when examining a large marine aquarium, I was surprised at the number of dead bees floating in it, and they, I imagine, must have been attracted to it by the saline matter. The room in which the tank stands is rarely used, or I should have noticed the circumstance sooner. I intend, however, in the spring to place a glass of sea water alongside the fresh water, in order to test whether the bees really have any preference of the kind. A glass of salt water which I placed in the window along with the fresh, and containing a fragment of seaweed, is perfectly clear, and a number of entomostraea, or water-fleas, are now rolling, and diving, and tumbling head over heels, as lively as if in a tide-pool. Indeed, the water in the tank just named, and which is as clear as crystal, has been unchanged for about five years, and it contains marine animals in perfect health, which have been prisoners during the whole of that time—a certain proof that with a little management water may be kept sweet for an indefinite period.—F. H. WEST.

BEES commenced carrying pollen here on the 26th of January, and on the 1st of the same month to breed, if they had ever ceased doing so, as I have seen young ones at many hives, and, amongst them, a few drones have made their appearance.—A LANARKSHIRE BEE-KEEPER.

TO MAKE BETTER YELLOW IN WINTER.—Give your cows a little bruised goose. The fresh juicy spines ground, or cut fine, will be much relished by them. It increases the milk, improves the colour of the butter, and does not impart the slightest disagreeable taste. I tried this in Wales with a dairy of seven cows, and we always had nice, sweet, yellow butter in winter.—HELEN E. WAYNEY.

TRADE LIST

J. Baily & Son, 113, Mount Street, Grosvenor Square.—*Trade List and Descriptive Catalogue of Poultry, Game, Pigeons, &c. &c. &c. and Aquatic Birds.*

OUR LETTER BOX.

FEDLING FOWLS FOR EXHIBITION. (*H. M.*)—Good quality of moulting quality, occasionally a little meat, and the yolk of new-laid eggs. Many give a few white peeps for some days before exhibiting, and the food on stale crusts steeped in ale or wine. The latter food must be given sparingly, and this distaste is apt to make them quarrelsome, even to their hens.

EGGS MISSED BY BEES.—We have little doubt that the sitting hen ate the eggs placed under her. We advise you to examine your nests more frequently, and to ascertain whether the eggs are all right under the hen. If her good qualities are such that it is important to save them to the yard, be careful to secure some eggs from her, and then let the cock have her. If this wish her first sitting, you may give her one more trial, but watch her closely, lest she should spoil or eat her eggs. If you can manage without her, kill her.

MAKE DRYEN COCK FOR FOWLS. (*M. T. S. J.*)—Put in a given either boiler or mangle. We consider it no fattening in any state for breeding stock, unless they are out of condition, and then to be given sparingly.

DURING GAME COCKS. (*L. J.*)—Take a curved pair of very sharp scissors—you may purchase them at Priest's in Oxford Street—cut the comb from over the nostril to the back of the head; close it, but not exposing the skull. If it bleed much, take a little feather and lay it on the wound, it stops the bleeding. You must also remove the gills and dentours. It is a great deal, but it is a small operation, and the birds are quite indolgent to it. The cocker always cut up the comb and threw it down for the cock to eat, he never refused.

PROLONGED INCUBATION.—I set a White Cochon hen on eleven of her own eggs on January 12th; not one of them was hatched out till the 5th of February, and then only two, five more during the following night, and the rest the next morning. Thus she was sitting more than twenty-three days. Is not this an unusually long time? I had ten hatch out altogether. One of my White pullets lays eggs the size of a Pouter's, with no yolk at all. What can be the reason of this variety? (*M. H.*)

It is not uncommon for hens to sit one day over their time; but we have seldom found them exceed that. Except when the eggs are carefully tended and soaked before hatching, they seldom come off altogether. A nest of eggs seldom hatches so closely together as is supposed. The eggs nearest the fan are hatched first, and the others in due order afterwards. We often have hens that begin hatching in the evening, and do not finish till the next day. The pullet will soon lay eggs of the natural size. It is not uncommon.

SICK PIGEONS. (*G. J. Lambingham.*)—Your Pigeons are most likely suffering from diarrhoea, so that their house is dirty and sheltered. If much affected give each bird at a pill containing a grain of calomel, then for a few days feed with cod-liver oil—you may mix it with ground rice, flour, or meal, a very little sulphate of iron in their water, and some old beans in their food. Some good breeding Pigeons under favourable circumstances will rear nine or ten pairs of young ones during the year, but there are so many casualties that few are able to bring up so many. Three or four pairs cannot be considered bad work for fancy Pigeons. One or two really good young ones ought to satisfy most fanciers. Very much depends on accommodation, breed, and season.—B. P. BENT.

RABBITS. (*J. P.*)—If you send seven postage stamps to our office, with your address, ordering "The Rabbit Book," you will have it sent free by post.

CANARIES DYING. (*Canary Lovers.*)—I have opened the dead Canary sent, but without being any the wiser as to the cause of the poor bird's death. The bird was much emaciated and the intestine looked dark, but it was too much crushed to say if they had been indured. The symptom you describe are just those of starvation. I am, therefore, inclined to think that there must have been something amiss with the seed—that the empty seed had been heated or in some way damaged, and, consequently, failed to nourish the poor birds. I cannot otherwise account for their deaths. You may ascertain this by biting and tasting the seed. You seem to have taken great care of your birds, but I think you make them too tender by not letting them enjoy fresh air, and covering them up at night is not the health plan. If sheltered from the wind and rain and not exposed to draughts the birds require a rather surprising. Birds that have been kept in a heated place and bred into song are necessarily in a very unnatural state, and require great care in raising them off. They may be expected to cease their singing when removed, but with care will soon resume it at this season of the year. The spring is a good time to buy birds at any of the London shops, as then you can hear them singing. I do not think there is anything epidemic amongst your birds. If they do not seem quite well you may give them a few grains of henbane, but this must not be made their constant diet. If the birds cough or are lousy, put a little Spanish Bismuth in their water; if purged, give them rice water to drink. In addition to cleanliness let your birds have fresh air and water to bite in.—B. P. BENT.

BEE FLOWERS. (*M. E. E.*)—Mignonette and borage will be the best in your town locality.

HIVING A SWARM. (*H. J. E.*)—When the swarm settled on the head of the old pollard, a little more was required than to stand a hive over it. Had this been done the bees would probably have ascended into the hive of their own accord, although their movements might have been accelerated by a few whiffs of smoke. We had a swarm last summer which clustered among the large branches of a pear tree, just at their point of union with the trunk. In this case we merely supported a straw hive just over the swarm with the left hand, whilst we struck the trunk of the tree with the open palm of the right. The vibration thus produced sent the bees up into the hive with great rapidity, and the entire swarm was speedily hived in the most satisfactory manner.

SILVERWORMS. (*C. P. J.*)—The leaves of the common mulberry are the food they prefer and thrive best on. If you have Vol. X. of our First Series you will find full directions there for their management. It is in Nos. 245, 246, 247, 248, 250, and 252, all of which you can have free by post from our office if you enclose twenty-four postage stamps with your directions.

PEAT EARTH AS A DEODORISER. (*Escreta.*)—All soils are deodorisers, but peat earth we should expect to be the least powerful. It is chiefly composed of silica and vegetable fibre. A dried loam, rather tenacious than light, we consider the most efficient earthy deodoriser.

WEEKLY CALENDAR.

Day of Month	Day of Week	FEB. 27—MARCH 5, 1866.	Average Temperature near London.			Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon. Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

5	M	<i>Acacia rotundifolia.</i>	48.9	31.9	40.4	15	39	6	45	5	18	10	3	8	18	11	43

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 48.9°; and its night temperature 33.1°. The greatest heat was 70°, on the 4th, 1860; and the lowest cold 15°, on the 4th, 1852. The greatest fall of rain was 0.81 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

CULTIVATION OF CAMELLIAS.

AMELLIAS are, perhaps, more generally admired than any plants requiring the protection of glass. When in perfect health their dark glossy foliage and glorious flowers

render them the pride of the conservatory, whilst a single bloom is thought to heighten the charms of the most beautiful woman. Knowing from practical experience that no plant is more easy to grow than the Camellia, I have no hesitation in saying that none is more generally mismanaged. It is rarely indeed that we see Camellias in health, whilst plants with yellow unhealthy foliage, attenuated shoots, and covered with scale insect, may be seen in almost every greenhouse.

It is most remarkable that when so many new and beautiful varieties are being introduced, rendering Camellias more than ever worthy of cultivation, so few of our large nurserymen pay any attention to their propagation; but the reason is obvious, they do not pay. Thousands of young Camellias are introduced every year from the continent, nice-looking bushy little plants, well set with buds, and they are sold at a price for which they cannot be grown properly in England. Though a large proportion of these cheap plants die, and more become permanently unhealthy, the public still buy them, and their doing badly is attributed to the mismanagement of the gardener, or the conclusion is arrived at "that Camellias are tiresome plants to grow," and the attempt to cultivate them is given up. In proof of what has been advanced, we have only to take this fact into consideration, that whilst a young plant may be purchased for 2s. 6d., a bloom at Christmas is worth 1s. in almost any town in England.

The Camellia is nearly as hardy as a Portugal Laurel, and if it were planted in proper soil, and covered with a glass roof, no English winter would injure it; but, grown in small pots, its roots would suffer. If a healthy plant be examined, it will be found that its young roots are matted round the inner surface of the pot, and, of course, if that pot be exposed to severe frost such roots are likely to be killed. Artificial heat, therefore, is necessary to prevent the temperature falling below the freezing-point. I have no hesitation in saying, that all fire heat more than is requisite for this purpose is injurious to the Camellia. It is quite true that Camellias may be forced, and that to stimulate the vitality of an unhealthy plant a moderate damp heat may be advisable, but forcing in most cases is injurious to health and longevity; and it does not follow that the same treatment is adapted to health and disease. To grow a healthy vigorous plant of good constitution is a work of time, but Camellias may be grown, as razors are manufactured, "to sell."

PROPAGATION.—Though the improved double Camellias may be grown from cuttings, they rarely make healthy or permanent plants; they ought, therefore, to be grafted on the single Camellia japonica.

Those who raise many seedling Camellias with the hope of obtaining new and valuable varieties, often use those which prove inferior as stocks; these may be as good as the original single Camellia for the purpose, but they are often little superior in vigour to the double varieties which are worked upon them.

Cuttings of the half-ripened wood of the single Camellia should be taken in August; a pot properly drained, and half filled with sandy loam, should be filled to the brim with fine white sand, which, when watered and made solid, will be fit to receive the cuttings. These will require a gentle bottom heat and close atmosphere, and will be ready to pot off in the following January.

SOIL.—The roots of the Camellia will not grow in solid soil, it must be loose and open; knowing this, the continental growers use a rich fibrous peat, and if the plants be carefully shaded, the atmosphere damp, and everything else favourable, it is probable that no soil will grow young Camellias in less time or with better-coloured foliage, but I am convinced that plants so grown have no constitution. After many years' experience I have come to the conclusion that turf from a sandy loam is the only soil fit for Camellias, and that the addition of leaf mould, peat, manure, &c., is always injurious. Cut the turf as thin as if it were intended for a grass plot, chop it, or, what is better, pull it to pieces, and use it the same day it is cut; it will not improve by keeping. In using so fibrous a material considerable pressure must be employed in potting, otherwise it will be too loose; a little fine soil sprinkled on the surface will give an appearance of greater neatness. A short time after the plants are potted a few blades of grass will probably spring up in the pots, but one weeding is generally sufficient.

POTTING.—In potting cuttings a more sandy soil is required than for older plants. After having well chopped the turf place it in a riddle, and give it a shake to get rid of part of the soil, and add as much white sand as is necessary to make it look like sandy peat. Use small pots holding less than half a pint of soil, and pot firmly. A moderately damp and close atmosphere of from 50° to 60° is necessary till growth has commenced, but no bottom heat should be applied, as the roots of Camellias are easily destroyed if plunged in a warm bed. When well rooted a cool house, facing the north, would be the best place to which to remove them, and there, with the ordinary attention required by greenhouse plants, and no more heat than is requisite to keep out frost, they may remain for two years, when they ought to be fit for grafting.

GRAFTING.—This is best performed in the beginning of January, and requires some skill on the part of the propagator. The stocks should be placed in the propagating-house a fortnight before grafting, that they may be a little in advance of the cuttings. Grafting may be done in the usual manner by what is called whip-grafting, the top of the stock being left on; or it may be done by what is called

saddle grafting, in which case the top is removed. The former has the advantage in one respect—that it can be repeated without much injury to the stock, in case the first graft fails, if the operator has taken the precaution not to graft too low down the first time; but it is not advisable to repeat the operation the same season. The latter mode is more sure, and makes the stocks and the plants, but a failure destroys the stocks. When grafted the stocks should be placed on mat in a hotbed, and kept close and warm till the scions are safely united. A clever paper grower will make fifteen out of twenty grow, whilst an inexperienced man will kill more stocks than he will make in a plant.

ADVICE TO GROWERS.—Treat the plants as half-hardy green-house plants; that is, give no more heat than is necessary to prevent frost. In watering use enough to soak through the pot, and never let them become too dry, nor give water till they are dying. Keep the foliage perfectly clean; if necessary wash them off with a sponge dipped in warm water, or soap and water, this is far better than using the syringe. If the plants are to be put in pots, it should be done as soon as possible after they are grafted, almost before they are out of bloom. Never tan the plants out of doors; if they cannot be placed in a house with a north aspect, use a shade in hot weather. Do not use the syringe except for a few days after they are rooted, when the same may be kept a little close to promote growth; all other times give plenty of air. Treated in this way the *Camellia* makes strong vigorous shoots and healthy foliage, and there will be no complaint of falling buds, dead roots, unhealthy foliage, or miserable flowers.—J. PEARSON, *Chilwell*.

THE COILING OF VINES.

I have derived humble satisfaction, and have been amply rewarded for the small trouble I took in transferring to your columns the opinion of my old French friend on this subject. If it had done nothing more than have brought out Mr. D. Thomson's opinion, as given in pages 82 and 84, I should have felt amply rewarded. Still I have a strong leaning towards the opinion of my old friend, a fruit-cultivator of upwards of three score and ten, with a hard head and a constitution equally hard, for he was at Tilsa with Napoleon in 1812, and returned unscathed, with the exception of being a "*l'oiseau* (cougher) for life," as he says.

In the second paragraph of Mr. Thomson's sensible article, he alludes to coiling as having roused discussion many years ago. It is not coiling of Vines, but coiling of Vine shoots in pots, so as to have a crop from them. Mr. Mearns was, I think, the inventor of the system, which failed.

In his third paragraph, Mr. Thomson thinks that coil planting is opposed to the laws of Nature. To bury in the ground the stem of a tree, which will not put forth roots, is a sure way of destroying a tree. Wherever I have seen earth heaped to a depth of 4 or 5 feet round the stem of a tree, so as to cover a surface of, say, 10 feet in diameter, thus excluding heat and air from the roots, certain death has ensued; but what shall we say to the proposition of "T. T.," page 132, that it "has a very beneficial effect." It is just possible that earth may be piled up close to the stem of a tree, so as not to cover the circumference of the surface of the soil, without killing it, and that is all. It may happen to stand near railway embankments, so that their roots are covered, they die. This is, however, very different to coiling a Vine, and covering it with 2 inches (misprinted "10 inches") of earth—every fresh root gives vigour. The vigneron of France would not constantly layer their Vines unless they experienced this effect.

In the fourth paragraph of Mr. Thomson's article, he confounds the covering of the shoot of a Vine lightly covered with soil with the planting of a Vine deeply. The difference is most material. He layers his Vines, and covers them 8 inches deep. The shoots were too deep to receive any benefit from those grand sources of Moisture and heat; consequently they put forth no roots, the sap circulated languidly, and the Vines suffered. If they had not been so deeply buried they would have put forth roots from every inch of stem, instead of having a bunch of roots only "close to their necks—near the surface of the soil," and if the numerous roots thus formed had a good compost to run into, they would have interfered with the original root, by leaving it but little to do; but they would have given immense vigour to the Vines.

In the fifth paragraph, the stems of the Vines alluded to were most probably too deeply covered, and shaded from the direct

rays of the sun by the front wall: under such circumstances they would not put forth roots. In old times, when Vines for sale in the nurseries were propagated by layers, I perfectly well remember a twist being given to the shoot before it was layered, which made it root more freely. This is an approach to coiling, the twist in which has undoubtedly been found, in France, to have the same effect.

Referring to the old system of propagating Vines for sale from layers, I well remember the long wall at the Brompton Park Nursery, in front of which the shoots of Vines from the wall were annually layered. I can recollect that here in a light sandy soil the layers rooted admirably close to the surface, at the collar, but the lower part of the Vine, which was buried 8 inches below the surface, was generally bare of roots.

In his sixth paragraph Mr. Thomson seems to have made a great mistake. One feels surprise that so clever a cultivator could have made such a *faux pas*. The roots of the Vines were buried to the depth of 15 inches below the surface; they, instead of imparting vigour to the "splendid Vines, with buds like nuts," ruined them by not moving, because they were out of the influence of light and heat, those essentials to life in everything.

It will, I think, be seen, that in no one instance has Mr. Thomson planted coiled Vines after the manner I endeavoured to describe in No. 248: still we owe him thanks for his kindness in saying what he has said, and in giving so lucidly an account of his experiments in Vine planting.

I have a strong idea that coil planting will be found better adapted for the pot culture of Vines, and for Vines planted in the area of a house (a vineyard under glass), than for Vines planted under rafters in the usual way. What occasion can there be for any change, when Grape culture is so perfect as it is under the management of our great gardeners? The planting of the area of a house, and training the Vines perpendicularly to rods, is equivalent to making a French Vine garden in England. I have a small span-roofed house planted with forty Vines trained after this manner. It was these Vines that brought out my old French friend, for he immediately laid hold of one and said, "You ought to have had double vigour in this Vine, and you might have had, if you had coiled it." This led to the description of how to coil a Vine, which your readers will find in No. 248.

As to my own doings, I have two dozen Vines in pots, placed on hot-water pipes. They were originally 8 feet in length: instead of reducing this length by cutting off the fine, plump fruit-buds at top, I have layered the base of each, coiling it round just inside the rim of the pot, and covering it 1 inch deep, so that my Vines are now a little more than 5 feet in length. With the exception of two or three, they are breaking well. I shall watch the coil as to its time of rooting, or not rooting, with much interest.

With regard to my "vineyard under glass," I intend to coil every Vine—this is the second year of their growth—and thus see if this very simple variation in the planting of Vines has any effect. I hope Mr. Thomson will visit London in May, to see the International, and I trust he will come here, so that we may "reason together." I always hail with delight the visits of our great gardeners, it is quite refreshing to contrast my eccentric ways with their sound and long-practised systems.—T. R.

MUSHROOM-GROWING IN POTS.

A CORRESPONDENT speaks of growing Mushrooms in pots; I have done so with very good success. Having some 18-inch pots I filled them with fresh droppings, and spawned them at once, setting them under a stage through which passes a hot-water pipe covered with a grating, and placing a mat over the pots. I find the Mushrooms so produced very useful when beds are perhaps longer in coming in than calculated on.—W. McC.

NEW HYBRID AZALEA.—I send you some blooms and foliage of what I consider to be one of the greatest acquisitions in the way of early spring-flowering greenhouse plants I have seen for a long time, and I shall be glad to have your opinion of it. The plant has been brought to me for inspection, and, as soon as I saw it, I told the fortunate owner of it that I considered it a novelty of first-class merit. The description which I received of its origin is, that it is a seedling from the pretty and useful Azalea named *amena* crossed with *Rhododendron Princess Alice*; but, from the general character of the flower, I

should be inclined to think that it has more of the characteristics of *R. Gibsoni* than of *Princess Alice*, although the foliage favours the latter variety more than the former. The flower is of about the same size as that of *R. Gibsoni*, and the colour is a rich rosy peach; the foliage is about double the size of *Azalea amœna*, rather more elongated, and is covered thickly with short copper-coloured hairs on the upper surface of the leaf. The plant is all that could be wished in point of habit, and it appears to possess the free-flowering character of *A. amœna* combined with the large flower of *R. Gibsoni*.—*J. WILLS.*

[The bloom was much damaged, but not to the extent to prevent our being able to say that the flower is very large, of good substance, and of a deep rose colour. Mr. Wills's opinion upon the plant needs no confirmation.—*EDS.*]

TROPICAL PLANTS IN OPEN BORDERS.

CURIOSITY and admiration have been largely evinced at the recent experiments, so happily conceived and so successfully carried out, in the summer embellishment of a few of our London parks, by the employment of varied selections of plants which, until lately, were regarded by most English gardeners as only adapted in this climate to perpetual imprisonment under glass. Now, why should there not be a judicious selection and association of what are called "sub-tropicals" with our present florists' flowers? With this object in view a piece of ground favourable to their growth might be set apart in some of the extensive parks belonging to the nobility, or at least in our public gardens. The plants in question deserve the serious attention of all desirous of decorative improvement, particularly when their employment, in relation to our present system of filling up, would entail very little additional trouble or expense. The only serious objection to their general adoption in the more temperate and dryer parts of the country seems to be want of house-room for their winter preservation; but this is more seeming than real.

To many persons who visited Battersea Park during the last few seasons it would seem incredible that what garnished a vast portion of that extensive area with the varied and luxuriant vegetation of a sub-tropical garden, could be housed and preserved during the winter months in the little space provided for the purpose. That such a multitude of plants should be turned out in summer with means so limited as compared with their number, will not, however, seem so wonderful when we consider the extraordinarily rapid annual growth of most of them—such as *Caladiums*, *Cannas*, some of the *Malvas*, *Solanums*, and *Leguminosæ*, the different varieties of the *Castor-oil* plant, some of the *Composites*, *Aralias*, *Dracænas*, the different *Indian-rubbers*, &c.; and when we consider that the facility with which most of them are raised from seeds and otherwise propagated, renders it unnecessary, nay, unadvisable, to occupy much house-room in keeping through the winter many overgrown and deformed individuals, except a few which may be cut back and kept to furnish cuttings in the following spring.

The *Cannas* may be cut back on the appearance of frost, and the rhizomes stored away like the tubers of the *Dahlia*, or a great many of those with short-jointed rhizomes may be left out permanently, covering the beds with old hay, &c.; in fact, one of the finest beds of *C. limbata* at Battersea Park last season was treated in this way. The *Caladiums* will take their sleep, either unpotted or in pots, in any place where they can be kept dry and protected from frost; and a great many other plants are here passing the winter in cold pits. Among such are the *Rice-paper* plant of China; *Solanum auriculatum*, robustum, and marginatum; *Nicotiana wigandoides*; *Senecio Ghiesbreghtii* in full flower; *Verbesina gigantea*; *Polymnia grandis*; *Ferdinanda eminens*; *Cincaria platanifolia*; *Acanthus mollis*, spinosus, and lusitanicus; *Dracena indivisa*; *Grevillea robusta*; *Lomatia Bidwilli*, &c.; *Chamerops Fortunei*; *Berberis nepalensis*; *Melanthus major*; *Bambusa metake* and *B. aurea*, &c.; *Cassia floribunda*; *Phytolacca dioica*; *Erythrina ruberrima*, *E. crista-galli*, and *Marie Belanger*; *Gunnera scabra*; *Alsophila australis*, and *Dicksonia antarctica*, &c. The cold pits in which these are sheltered are only protected during the nights with mats, &c. It might not be safe to imitate this generally, but there is every reason to conclude that in pits well drained, and heated with a single small hot-water pipe, they would be perfectly safe, and would do well. The more delicate subjects serve to embellish and enliven the houses.

These experiments, I think, afford incentives to all—to those having some of these plants already in their houses, to put them out during the fine season—to those having the construction of houses in contemplation, to set a section apart for raising and cultivating some of the best.—*WM. KELLY, Battersea Park.*

IMPROVEMENT OF WILD FRUITS.

THE cultivated Apple having sprung from the wild Crab, the Pear, Plum, &c., from their wild progenitors, great encouragement is thus offered to horticulturists to devote attention to our wild fruits.

The Pear scion takes freely upon the White Thorn stock, and no doubt this Thorn will take as freely when grafted upon the Pear. There are great varieties in the size and quality of the laws in the present uncultivated state; but these circumstances evidence a predisposition to vary and improve, and if due cultivation and selection were given, it is impossible to say what results would follow. Last year I grafted the double and single scarlet varieties, and the American Thorn, on Quince and Pear stocks, but the season was unfavourable to the success of the careless mode which I adopted, and the dry winds destroyed most of the grafts; afterwards dogs and fowls completed their destruction, except one American Thorn, which took well and grew about 2 feet, the stock being the Quince. I propose to repeat the operation this season, and I now write in the hope of inducing some of your experimental readers to devote attention to the same or more extended objects.

I intend to graft the common White Thorn on the Pear stock, also upon the Quince already grafted with the Pear, as well as on the Quince stock, in the hope that an early state of fruitfulness may be induced, so that I may take scions from the seedlings from these grafted Thorns. At my rate, *Crategeus coccinea* and *lutea*, with *C. pyracantha*, if grown upon the Quince, and then cultivated upon Mr. Rivers's system of nipping-in and repeated removals, would, no doubt, be very ornamental as dwarf pyramids and bushes. I am informed by a very talented old gardener that the *Cydonia (Pyrus) japonica* takes readily upon the White Thorn, and, therefore, probably upon the Pear and Quince (*Cydonia vulgaris*), and thus it offers results both in ornamental and fruit improvements.

The *Pyrus sorbus*, or True Service Tree, may be propagated by grafting upon the Apple and Mountain Ash, and is said to take upon the Medlar and Hawthorn stock; but I am working it upon the Paradise, with a view of seeing the effects after years of cultivation upon the nipping-in and repeated-removal system. As far as I have gone I find the Apple when budded upon *Pyrus sorbus* does not grow freely, but grafting has done better. I really think that the *Pyrus sorbus* gives much promise of affording a very useful addition to our garden fruits, and the same with the haw, at least for preserving. Till careful trials have been made and attentive cultivation bestowed, we cannot say what may be done, and should the effect be only to induce any of these to cross with greater facility than they do, a new race might arise affording much interest.—*W. A. WOOLER, Sudbury Hall.*

MANURE FOR POTATOES.

I MADE an experiment on a small scale last season, which seems to me to prove Turnip manure to be likewise a good Potato manure. I staked off exactly one rod of my garden, which is a very light sandy soil, and sowed at planting-time 3 lbs. of Turnip manure (value 2½*d.*) At taking-up time I weighed the produce, and found it to be 20 lbs. more of large and good Potatoes than the same quantity of land on either side of the manured rod produced; and if I had measured the small and diseased tubers the difference would have been much greater, as, although there were less small ones on the manured rod, the diseased (and they were the largest), were much more plentiful. The price of the 20 lbs. of Potatoes in this part is about 6*d.*, leaving 3½*d.* balance in favour of the manured rod, or £2 8*s.* 9*d.* per acre.—*J. TOMLINSON, Blyton.*

AMHERSTIA NOBILIS.—Those who have the interest of plant culture at heart, will be glad to learn that a splendid specimen of this rare Indian tree is now in flower at Chatsworth, where it is grown in a house especially designed for it.

PARADISE STOCKS.

I was much surprised at reading the letter of Mr. Pearson last week, condemning the Paradise stock for Apple-grafting, as I had eagerly to see what would be written in reply, as I am laying out a new garden, and I intended to plant largely of the Apple on the Paradise stock. I am disappointed to find no cue but Mr. Scott replies to the letter. What has Mr. Rivers to say on the subject? It was from his recommendation I took the idea, and I have his last catalogue before me, in which he very strongly recommends the Paradise stock, and after quoting prices, says in a footnote, "These kinds of trees will be planted extensively in gardens, and, in fact, revolutionise Apple-tree culture." Nothing is more puzzling to the amateur than these very contradictory opinions from leading and experienced men.—J. D.

There seems to be a great misunderstanding arising from Mr. Pearson's observations about the Paradise stock. What Mr. Pearson spoke of, and what Mr. Scott recommends, is the *Pommier de Paradis* of the French, a very different tree from the English, the Dutch, and the French Paradise stocks which are used in this country, and one or other of which Mr. Rivers alludes to in his catalogue and "Miniature Fruit-Garden," where he recommends plantations of Apples grafted on the Paradise. What we call the French Paradise is by the French themselves called the *Daucin*; but all these three are entirely different from the *Pommier de Paradis* that Mr. Scott recommends. Our own experience of the last is, that it is tender, impatient of cold and wet, and subject to canker. We have cultivated trees grafted on it successfully in pots, for which purpose it is well adapted; but unless in a light warm soil and a very favoured situation, we should not be disposed to place any reliance upon it.—Ems. J. or II.]

VINE CULTURE.

I should have been better able to have replied to "T. S. W.'s" criticism in No. 257, page 24, and should have felt more pleasure in doing so, had he put his name in full at the bottom of his article, instead of taking shelter under initials.

It is true I invited a discussion on the Vine, and should have been very much pleased to have been corrected, and would not have been slow to have acknowledged an error if it had been pointed out to me in a friendly spirit, and according to the rules of the news. "T. S. W." seems to have forgotten this. He says, "Vine culture is a subject that has been so often and so thoroughly sifted of late years, that it would be difficult indeed to brook any new or profitable idea upon it—a fact which your correspondent seems to have been unable to overcome."

In reply to this—1st, I ask "T. S. W." Is the cultivation of the Vine to stand at the point of perfection at present gained, whilst ever thing else is progressing?

2nd, "T. S. W." is wrong in assuming that I was attempting to introduce any new system of cultivation for the Vine. What I preach I practise—none of my articles are copied from other works, but are simply descriptive of my own everyday experience.

As to the red spider difficulty on which "T. S. W." lays such stress, I maintain that the insect may be easily kept under if the proper means are adopted from the beginning of the forcing season to the fall of the leaf. "Prevention is always better than cure." With regard to the proper mixture to be used for painting the Vines, &c., "T. S. W." seems to have been brought up in an age when none of the old-fashioned plans of our forefathers were ever heard of. If I saw any of my Vines undergoing such a severe process as that described by "T. S. W." (with the hard spoke-brush), I think I should want a stimulant rather stronger than water to prevent me from fainting.

As regards lowering the tops of the Vines, I still adhere to what I stated in No. 242, page 398. I have grown Grapes which have been deemed worthy of a first prize at the metropolitan exhibitions; they have been cut from the middle of the Vine. I also noticed that the wonderful bunches of Grapes exhibited by Mr. Meredith during the past and previous seasons had been principally produced about the centre of the Vine. If the hot-water apparatus has been properly fixed, there will not be a very great difference in the temperature of any particular part of the house. What I mean by properly fixed is to have the pipes equally distributed over the floor of the house, or above the Vine-border, instead of having them principally at

the front and back of the house, as was usually the case in days gone by.

In late vineries I consider the regular breaking of the Vine may be attributed more to the approach of its natural season of growth than to any other cause at that period. The difficulty to contend with is how best to keep the Vine back. Fire heat will seldom or never be required in a late viney while the Vines are breaking, unless the weather be very cold, which is sometimes the case.

I admit "T. S. W.'s" to be a good plan—I mean the laying the Vines horizontally along the front of the house. It is a plan which I formerly adopted myself, but have discontinued for this reason—in bringing the Vines into their proper position, many of the finest and most prominent buds are often sacrificed.

With regard to temperature, my experience teaches me that it is better to err by subjecting the Vines to a moderately low temperature, than to force them into a premature growth before there can be a reciprocity of action between the roots and foliage. I consider a high night temperature quite contrary to all reason—all plants should be at rest during the night; and in forcing a plant of any kind into growth before its natural season of growth arrives, I maintain that every precaution should be used to bring this about as gradually as possible; and I have found in the course of my practice, that Grapes will colour much better in a temperature of from 70° to 75° than they will if subjected to a higher temperature. I have often had the thermometer in my vineries down as low as 46°, where the heating apparatus has not been sufficient to do the work properly, without noticing any ill effects resulting from it. I have also frequently seen a good crop of Grapes nearly spoilt by being subjected to a high temperature.

For the above reasons, therefore, I hold that the system of treatment which I have given is the safest one to go by, for that class of readers of THE JOURNAL OF HORTICULTURE for whose guidance my series of articles on the cultivation of the Vine were intended.

With all due respect to "J. S. S." No. 248, page 519, I must beg to be allowed to differ from him in opinion as to the use of the pruning scissors. I still maintain that it is impossible to make a clean cut with them; and that, however careful the operator may be in using them, the wounds never heal so quickly, and in many cases not at all.

I trust that these pages may yet be enriched by articles from some of our champion Grape-growers; and I am sure that the Editors will not refuse to insert any articles on the above subject, written in a friendly spirit, and for the general edification of that class of readers of the Journal who are not slow to acknowledge the benefit they obtain from conning over its pages, and who anxiously watch for its arrival by post.—J. WILLS.

THE ESSEX RIVAL PEA.

At page 66 of THE JOURNAL OF HORTICULTURE, is an inquiry from a correspondent who signs himself "NICKERBOB," as to the parentage of the above valuable Pea, and Mr. Eley, who has spared neither pains nor expense to introduce it to the public, has replied with the honest spirit of a true Englishman, to the effect that if "NICKERBOB" will give his real name, he will answer his inquiries; but your correspondent has not thought proper to do this either privately or publicly. He, also, under the disguise of his *nom de plume*, charges Mr. Eley with sending out a Pea as a new variety which has long been known in Nottinghamshire and Leicestershire. I happen to know that Mr. Eley has been indefatigable in his exertions to prove the Pea in question identical with any known variety, and the principal seed merchants, who send representatives all over the country, and many eminent gardeners, have failed to recognise it, but have furnished ample testimonials to prove its superiority.—T. J. S.

SUSSEX FLORA.—Mr. W. B. Hemsley, assistant in the Kew herbarium, is engaged in collecting materials for a Flora of Sussex, and solicits the co-operation of resident botanists and others interested in the issue of such a work. Local lists, especially of the extreme west and north-west, also information relating to critical species and specimens of the same, would be of great service. It is intended to include lists at least of the lower Cryptogamia. Names of intending subscribers will be

received, as the success of the undertaking depends upon securing a certain number. Communications may be addressed to The Herbarium, Royal Gardens, Kew, W.

CULTURE OF HOYA BELLA.

Of the several species of this genus, none is more worthy of careful cultivation than the subject of the present notice. It requires a free, porous soil, composed of loam and turfy peat, the latter chopped up with the spade, or broken with the hand, but not sifted, one-fourth leaf mould, and as much white or silver sand as will give the whole a greyish appearance. In this compost the plant will grow luxuriantly, and produce its lovely wax-like flowers in profusion. The pot must be carefully and efficiently drained, as a sour soil occasioned by an undue retention of moisture is extremely detrimental to the plant; bits of broken bricks and lime rubbish form a superior drainage, and if a handful of the latter is mixed up with the soil at the time of potting all the better.

During its season of active growth the Hoya bella delights in a moisture-laden atmosphere, and a temperature of 70°, and upwards; with plenty of moisture in the air, only a very limited supply will be required at the roots, and hence the moist atmosphere of the plant-stove or Orchid-house is that most congenial to the habits of the plant. In a well-managed vinery, however, the plant may be pretty successfully cultivated. If grown in the stove or any other glass structure where a high, moist temperature is steadily maintained, the plant should be removed to a drier and somewhat cooler atmosphere—say, one with a temperature of 65°, when the flowers are on the eve of expanding; the blooming season will thus be very much prolonged, the high, moist temperature of the stove speedily causing the flowers to drop off.

In order to secure a proper ripening of the wood, a late autumn growth should not be encouraged, but if the plant has been kindly treated during summer, this important result will, in general, have been pretty well accomplished by the time its blooming season is over. In winter it should be accorded a dry shelf pretty close to the glass, where the temperature ranges from 55° to 60°.

When grown as a specimen pot plant it is not unfrequently trained to a balloon-shaped wire trellis, and for certain purposes it suits very well. It is also occasionally used to cover the end wall of a stove; but if we are desirous of showing flower and leaf to the greatest advantage, it should be plunged in a wicker basket of moss, and suspended from the roof of the stove or vinery. It here assumes a semi-pendant habit, and has an extremely graceful appearance.

Almost the only management which the plant requires, is to pinch the points of the leading shoots or branches during the growing season, so as to induce the production of laterals, and thereby secure a bushy habit. If this pinching be duly attended to, a severe knife-pruning will rarely be necessary. Early in spring the plant should be top-dressed or repotted, as may be necessary, and then be placed in moist heat and treated as above directed. It is propagated from cuttings, which root freely in moist heat.—J. DUNN.

NOVELTY AND EXCELLENCE ARE NOT TWINS.

BEFORE reading Mr. Robson's remarks it had often occurred to me that after all the novelties duly trumpeted forth year after year, in reality little improvement had been made for say the last ten years. Since reading the article above referred to, it strikes me that it would prove interesting to many of your readers were you to set up in your pages a kind of tribunal, and bring before your court fruit, flowers, and vegetables. Let them all give some account of themselves—what they have been doing, or rather what has been done for them during the period stated, taking evidence *pro* and *con*. In fact, let there be a day of reckoning. After all, what is the use of going on year after year, trade excepted, saying this or that is better than so and so? To my mind the proof of many things besides the pudding lies in the eating. Give me in the way of Pears a Jargonelle, in Apples a Cornish Gilliflower, and in Peas the British Queen. Can any new kinds be advanced that will beat them? If so, the information will greatly oblige.—AN OLD BIGOT.

[If our most inveterate enemy were permitted to afflict us in any way he chose, he could not devise a more effectual torment than to compel us to be judges of such a tribunal as you sug-

gest. We humbly decline accepting the appointment, and transfer it to the Committees of the Royal Horticultural Society.

You are worthy of your adopted name if you admire none but the three specialities you have named. You cannot have even a succession of them.

Of Apples, just try the Kerry Pippin, Cox's Orange Pippin, and Sam Young; of Pears, Marie Louise, Winter Nelis, and Williams's Bon Chrétien; of Peas, Advancer for an early crop, Champion of England and Ne Plus Ultra for later crops; and then, instead of "An Old Bigot," we shall have you in our pages as "A Young Convert."]

SYRINGING VINES—INFECTED CLOTHES.

THE syringing of Vines is a subject respecting which much discussion has taken place, and it has even been considered possible to modify, if not altogether discontinue its use as a preventive of red spider in forcing vineries, and thus save much valuable time.

For several years I have been endeavouring to find a substitute for syringing, as I never observed that the Vines derived any benefit from it. On the contrary, the results are often the reverse of beneficial, from the fact that if air is not given early next morning the sun is sure to burn or scald the tender leaves of the Vines, by its action upon the water adhering to them.

In houses of small dimensions, constructed without ventilators at front and top, burning of the foliage will frequently be your reward.

Here, last season, we never used the syringe, and its discontinuance was attended with entire success. The Vines had nice clean foliage, short-jointed wood, and were free from red spider.

I think that by keeping the walls, flues, and floor constantly damp, the necessary amount of moisture may be produced to hold the red spider in check.

Previously to commencing forcing, pruning being done, I would have the Vines carefully painted with sulphur and Gishurst compound, and the walls with lime, Gishurst compound, and sulphur; the flues might also be washed. These applications, repeated several times during the forcing season, will be found effectual in preventing the attacks of red spider, should the insect not be carried to the vinery from other places. For instance, when the person in charge has been attending to Melon or Cucumber-pits, where the red spider frequently abounds, he may carry the insects on his clothes and deposit them in other structures. I would suggest that such introductions be prevented by having the clothes carefully brushed before entering the vinery. I would also warn the young gardener of the possibility of carrying mildew into the vineries, which might be done if he went there after having gathered Peas or other vegetables affected by that pest of the garden, and if it be true that the same fungus appears on the two plants.—JAMES REID.

POT VINES ATTACKED BY THE VINE WEEVIL.

I FORWARD for your inspection a one-year-old pot Vine which has been attacked by what I suppose to be the Vine weevil. I have hitherto been very successful in growing pot Vines, but this year I find they will be a total failure through the ravages of this pest. It is during the time they remain in the grub state that they feed upon the young roots of the Vine; and as the spring or forcing advances they assume the beetle state, and come out of the pots by hundreds.

Our Strawberry plants, too, have suffered very much from the ravages of this insect, both those in the open quarters and others potted for forcing; it was by this means they were taken into the forcing-houses.—J. B.

[The bark on the specimen sent was entirely eaten off from the roots of the Vine down to the wood, and from its stem, also, as far as it was beneath the soil's surface. The insect is the well-known *Otiorhynchus vastator*, and if not carefully hunted for and destroyed (as recommended in last week's answer to "WATSONIAN"), it will in a short time gnaw off every bud as it appears on the stems. A sheet or white cloth should be spread beneath the Vines, and the beetles hunted for at night with a light. They will fall to the ground and feign death on the slightest alarm.—W.]

MILDNESS OF THE SEASON.—The weather here (Welwyn, Herts), has been so extremely mild as to induce some of our

roses to bloom. We have here, on the side of a hill, a fine Rhododendron in full bloom, which has been expanded since the 6th of January, and on the 10th followed numerous patches of Snowdrops and Crocuses, exhibiting their early blooms. Fuchsias and Nectarines are swelling their buds and promise a good crop. Gooseberries are pushing into leaf, and, in fact, vegetation is here, in an active state, and, as Mr. Record stated in your Number of the 13th inst., every gardener should keep a sharp eye to the weather, and be in readiness for any of those severe frosts and winds which so often prevail in March.—H. O. G.

ROYAL HORTICULTURAL SOCIETY.

FEBRUARY 20TH.

FLORAL COMMITTEE.—Considering the cold and frosty day, this meeting may be considered a great success. Had it not been for the intense cold many other specimens, we are informed, would have been sent. Mr. John Graham, Cranford, exhibited a large collection of The Cam Violet, which maintains its character, and was universally admired both for the size of the flower, its sweet scent, and the noble foliage. Mr. Graham sent another seedling from this variety named Deumar, but very inferior. A special certificate was awarded for the collection. Mr. Young, Highgate, sent a small collection of Dracænas, and a specimen of Eryophyllum edgemoium. Mr. John Watson, St. Albans, sent plants of *Cyrtiochloa oxyedrus*, vars. *alba* and *rubra*. These plants appeared to be novelties. The foliage was similar to that of the *clausaria*; but as the merits of the plants consist in the corolla they possess, not bearing any they could not be noticed. Mr. Scully, North Hill, exhibited a seedling *Primula sinensis* with large bright flowers and Mosses, Garraway, Bristol, five seedling *Hippocrepis*—Nos. 1, 2, and 3 very showy flowers, but not equal to many now. From Mr. Bull came three varieties of *Camellia japonica*—*Bonanza*, the bluish flower, good shape, but small; *Archduke Carlo* de Teschauer, light red with occasional white centre petals, giving a very pleasing character; flowers small; also *Countess Novello*, white flowers, with pale bluish blotches. Messrs. Cutbush, Highgate, exhibited a large and interesting collection of *Azaleas*, *Magnolia Soulangiana*, *Primulas*, *Prunus sinensis*, *Hyanthids*, *Narcissus*, *Talips*, *Crocus*, &c., for which a special certificate was awarded. Mr. Lucking sent a nice specimen of *Papromia trifolia*, one of the plants collected by Mr. Weir, and which has been previously noticed. From Messrs. Water & Godfrey came three specimens of *Aneides japonica* var. *in full berry*. One specimen was extremely ornamental. A special certificate was awarded them. W. W. Saunders, Esq., exhibited a group of very small-flowering *Orchids*, among them some curious and interesting species, some of them highly scented, and others of botanical interest; a special certificate was awarded them. From the same gentleman came *Papromia species nova*, with bright green, small, ovate foliage—a trailing plant, useful for baskets and wall decoration. This curious *Papromia* was much admired, and was awarded a first-class certificate. This is another of Mr. Weir's plants. Also *Tillandsia bulbosa*, a great curiosity, growing on a small branch of a tree, and producing from the scaly stems long roundish leaves, which become a rich scarlet at the part where the purple flowers are produced. Although an old and well-known plant, few persons present had seen it in such a state of perfection. A second-class certificate was awarded it. Several very excellent specimens were sent from the Society's gardens, among which were *Dracænas*; *Cineraria populifolia*; a terminal *Orchid*, *Pectis bicolor*, with broad spotted foliage; and *Lilium floribunda*, a beautiful and decorative winter plant, with dark orange and bright yellow flowers. To this a first-class certificate was awarded; also a *Cattleya* collected by Mr. Weir, a beautiful variety of *C. Triana*, having a bluish flower with a deep purplish lip, differing from *C. Lindleyi* and *Mossii*.

FRUIT COLLECTION.—On this occasion there was an excellent, it might almost be said excessive, display of fruit, collections being furnished by Mr. Ford, gardener to W. E. Hubbard, Esq., St. Leonard's Lodge, Hordland; Messrs. Rivers & Son; and Mr. Lynn, gardener to Lord Boston, Hedsr. Each of these exhibitors received a first-class certificate. Mr. Ford's collection comprised a dish of Limes (*Citrus limonia*), one of Oranges, and a seedling Apple, which the Committee requested might be put again at an earlier period of the season, as it appeared to have been kept too long to be at its best; also, many different kinds of Apples and Pears. Among the former were good dishes of Norfolk Boring, London Pippin (very well coloured), Pearson's Plat, Keddleston Pippin, Shepherd's Seedling, New Rock Pippin, Dutch Main, Golden Harvey, Court-Pendant-Flat, Blenheim Pippin, Scarlet Nonpareil, Adams' Pearmain, French Crab of 1861 and 1862, Manningtons, Royal, and Heart-shaped Pearmain, Cornish Giffiflower, Bess-Bloom, very highly coloured, under the name of Black Jack, and several local varieties, one of which, called Elstead Pippin, was handsome in appearance, and it was said to be useful both for dessert and culinary purposes. Mr. Ford had also some good Uvedale's St. Germain Pears, Tregone Maroon, another stewing variety, March Boscot, and Easter Pearre, with &c.

Messrs. Rivers's collection consisted of Apples, chiefly American, grown on dwarf bushes worked on the English Paradise stock, and

was exhibited to show the effect of the warm season on the colouring and smoothness of their skins. They comprised Calville Blanche, to the merits of which attention was drawn last week; Calville St. Sauveur, Melon Apple, high coloured and very showy; Esopus Spitzenberg, Rhode Island Greening, Boston Russet, Baldwin, Newtown Pippin, Allen's Everlasting, and some others.

Mr. Lynn sent Black Hambrogh Grapes, plump and in excellent preservation; Hudson Winter Prolific Cucumber, of the Lion House race, and from the cluster of young fruit accompanying it apparently justifying its name; and a collection of Apples, consisting of Cox's Orange Pippin, Lewis's Incomparable, Bess-Pool (very sound), Sturmer Pippin, Scarlet Nonpareil, Cooke Pippin, Danmow's Seedling, French Crab, &c.

Mr. Watson, St. Albans, sent a seedling Apple, supposed to have been raised from a seed of Wheeler's Russet, but the Committee wished to see it again earlier in the season before passing an opinion on its merits.

Mr. Hill, gardener to R. Sneyd, Esq., Keele-Hall, sent remarkably fine fruit of the Madras Citron, along with the foliage, likewise preserves made from the green and the ripe fruit, of which the former was declared by the Committee to be the better. This exhibition well merited the first-class certificate which was awarded to it. Mr. Hill also contributed bunches of Lady Down's and Golden Lady Down's Grapes, to show their excellent keeping properties.

SCIENTIFIC MEETINGS.—Lord Henry Gordon Lennox, M.P., in the chair. The awards of the Fruit and Floral Committees having been announced, the Rev. M. J. Berkeley proceeded to remark on the subjects exhibited. A beautiful variety of *Cattleya Triana* first came under notice; then plants of the common *Hyanthid* and *Narcissus tazetta* imported from Persia, and sent by Dr. Hooker to show the difference between the improved garden varieties and the species from which these have been derived. *Lilium floribunda*, with *Correa*-like flowers, from South Brazil, was next referred to, and the account of it given by Professor Morron in "La Belgique Horticole," where it is truthfully figured and described. The next subject which came under notice was a male catkin of *Willingtonia gigantea*, from the Marquis of Huntley's, Orton Lomville, near Peterborough, where there is an avenue of *Willingtonias* upwards of 2000 yards in length, and from a tree in which the specimen shown was cut. Mr. Berkeley remarked, that although this noble Conifer had borne cones in various parts of England, this was the only instance which had come to his knowledge of its having produced male catkins, and there was now, therefore, a chance of its seeding in this country. A Gourd grown in Mr. Berkeley's garden in Northamptonshire then occupied attention; it was stated to be a variety of *Cucurbita maxima*, of which the seed had been imported from Valparaiso, to be excellent for *puces*, and to far exceed *C. ovifera* in quality. He trusted to be able to make up a considerable number of packets for distribution; and whilst on the subject of Gourds he would mention that among the Society's collections of flower and vegetable seeds to be distributed this spring was one called the Portmanteau de Naples, a large sort, very distinct from others, and requiring the assistance of a wall to ripen it. A mould infesting the stems of Dahlias was then exhibited. This was stated to be the *Botrytis* fungus of Greville, and to be very abundant under the microscope when the threads were freed of air-globules, which might be done by the aid of alcohol. Attention was then directed to the fungus attacking the leaves of the Pear tree, from which almost every cultivator suffers more or less, and which had been figured by Sowerby many years ago. This, which is known as *Ascidium cancellatum* or *Rustella cancellata*, had been identified by M. (Ersted), a Danish professor, as being only a form of the *Savin* fungus (*Pectisoma Sabinae*), and M. Ersted had succeeded in developing the sporidia of the latter on the leaves of the Pear. It was further stated that M. de Bary had found that in a similar way the Wheat Rust (*Puccinia graminis*) and the Berry Blight (*Ascidium berberidis*) were forms of the same fungus, and that therefore there was some foundation for the popular notion as to the connection of the last two. (Some account of the experiments on the identity of the above funguses was given in the "Florist and Pomologist" of October, 1865.)

Mr. W. Wilson Saunders then offered a few observations on the small group of *Orchids* mentioned in our Floral Committee report, and which some, he said, might call "micro-series of *Orchids*." Although their flowers were minute, these *Orchids* were not altogether devoid of some points of interest—perhaps to others as well as to botanists, and it was the duty of all Fellows to bring such subjects to the meetings. Among them was a *Lael. bilobus*, the blossoms of which possessed the merit of exhaling a delicious scent like that of the *Helleborus*, especially when the sun shone on them; those of another, *Epidermum hornidum*, had a delicate perfume like that of newly-gathered Primroses; whilst *Pelecia trilobus* was remarkable for the beauty of its structure. Mr. Saunders stated, that from great experience in the culture of these small species he had found them succeed best on thin slabs of wood or cork, and that these should be constantly wetted with the syringe on both sides, so as to afford a supply of moisture in addition to that which the plants obtain from the air of the house in which they are growing. With respect to *Tillandsia bulbosa*, which some found a difficulty in growing, it was merely necessary to place it on a little piece of wood, surround it with moss, and hang it up in the centre of a stove. Another *Tillandsia*—*usneoides*, hung down from trees like tufts

of moss, and would be an interesting plant for our stoves could it be brought across from the West Indies; but doing so always desiccated it so much that it would not grow. A small species of Peperomia, which had accidentally come along with some of Mr. Weir's Orchids, though but a stove weed, being of creeping habit, would run over soil or cover blocks of wood, in fact, would take any shape, and therefore might be useful for hanging-baskets and similar purposes.

No less than thirty new members were elected—a cheering sign of the increasing prosperity of the Society, and of the progressive interest taken by the upper classes in horticulture, and this increased prosperity and interest cannot fail to redound to the benefit of gardening and gardeners. The Society has passed through many vicissitudes, but now that there is so manifest a desire to extend its sphere of usefulness, if all classes will but unite harmoniously in its support, it may be made second to no other scientific body. It will then become capable of working out great results—results not of interest or benefit to a class only, but of importance to the whole community.

A PRETTY exhibition of forced spring flowers was made on Saturday. Messrs. Cutbush & Son again contributing most liberally to the general effect. These gentlemen sent a collection of miscellaneous plants very similar to those we have noticed as being at the last two meetings, a fine collection of forced bulbs, one of forced Hyacinths, and one of forced Tulips, to all of which awards were very properly made. Besides these, they had a group of finely grown plants of the double white fringed Chinese Primrose. Mr. Young, gardener to Mrs. Barclay, of Highgate, had a first prize awarded him for a collection of six miscellaneous greenhouse plants; and Mr. Bartlett, of Hammersmith, received the second prize. Mr. Young also exhibited a collection of cut Camellia blooms, which received an extra prize; and Mr. Bartlett received a similar prize for a collection of forced bulbs.

Mrs. B. Hooker, of Fulham, sent a basket containing a group of well-grown plants of fringed Chinese Primrose, with Hyacinths in the centre, which received a first-class certificate; and the Rev. George Chere, of Papworth Hall, received a similar award for a tray of excellent blooms of Anna Boleyn Pink.

Mr. Lynn, gardener to Lord Boston, Hedsor, near Maidenhead, exhibited a collection of fifteen varieties of Apples in an excellent state of preservation, to which a first prize was awarded.

Messrs. Lucking, Brothers, of Notting Hill, received a first-class certificate for a fine collection of forced flowers.

POTATOES.

SOME little time back I saw in THE JOURNAL OF HORTICULTURE, among the requests of correspondents, an expressed wish to know where the hybrid between the Ashleaf and Lapstone could be procured. I therefore wrote to H. Taylor, Esq., of Fenote, Bedale, Yorkshire, (who kindly sent it to me) for information. The following is his reply:—"I have made inquiry about the Potato you mention, which without doubt is the very best flavoured Potato in England. It combines many other good points. It is handsome for exhibition, smooth, a good cropper, second early, and the top not particularly large, but very handsome. It is distinct and highly spoken of by all who have tasted it. It keeps well until August. I mean new ones at midsummer, as well as old ones. It can be procured from Mr. Thomas Almond, Great Fenote, Bedale, Yorkshire, at 2s. 6d. per stone, bags included, under the name of the Yorkshire Hero Kidney. He has great demand for it, and has only fifteen bushels of it left."

Mr. Taylor supplies the following:—"Mr. Almond has another Potato, which he is increasing for sale in the spring of 1867. It is particularly early. He has it regularly in May in this cold part. It is a good cropper, smooth, free from disease, of handsome shape, distinct, top very handsome.

"We have another Potato here, most excellent. It is for winter. The flesh is white, and in flavour in my opinion slightly better than Yorkshire Hero. If you will accept a few of both the above I will send them to you, and a boiling into the bargain, so that you may taste and judge for yourself."

I will now tell you how Mr. Almond grows his early Potatoes. The land must be pretty good, and in good heart. He opens a trench, puts in long manure, sprinkles on this pigeon-dung, then gives a sprinkling of carbonate of soda. It appears that carbonate of soda has a great effect in producing earliness, and pigeon-dung forces the plant away. If this cannot be procured, substitute a sprinkling of guano.—W. F. RADCLIFFE, *Tarrant Rushton*.

INTERNATIONAL HORTICULTURAL EXHIBITION.—Dr. Seemann, having to visit immediately a portion of Central America, has been obliged to resign his Secretaryship of this Exhibition. Dr. Masters has been appointed his successor.

ROOTING VINE BRANCHES.

THE question as to whether it is judicious or injudicious to bury the stems of Vines in the border, with a view to their thus rooting more extensively and giving stronger wood than if the roots alone were covered, is certainly of importance. I planted Vines in both ways in inside borders, and observe no difference in the aftergrowth, the plants having done well in each case, and I have not courage to dig up the stems of those buried to see if these have rotted off or not.

Last spring I received some Vines from Mr. Rivers, to grow in pots standing on hot-water pipes. The rods would average, say, 9 feet each; but as the best wood and buds were near the tops, and I only wished to fruit the plants for one season, I coiled about 5 or 6 feet into each pot, and thus left only about 3 or 4 feet of the tops of each rod above the soil. The eyes broke well, and gave abundance of bunches, which ripened perfectly. By early stopping I compelled the eye next the earth in each Vine to form a cane for a future crop, and each of these canes had to be stopped many times to prevent the span-roofed house being darkened too much. I have now, from each pot, as fine bearing-like wood of these Vines as need be desired; and the pots being large, I shall be surprised if I cannot this year take a dozen good bunches from each Vine.

Is it likely I should have had such Grapes, and such wood, if the coiled stems of the Vines had died, and the plants had to depend for support on a new set of roots from a collar near the surface?—J. MACKENZIE, M.D.

[There are no rules without exceptions. If you have the chance again, would you repeat the experiment, and in the case of similar Vines, merely disbud the lower part of the stems, with the exception of one or two buds near the bottom? Choose one of these for a future stem, take a similar crop from the Vines treated in both ways, give the same treatment to each, and then let us know what difference there is in the appearance of the fresh shoots for next season.]

THE VERBENA DISEASE.—We regret to notice that a great number of the stock plants of this very favourite flower have died during the present season from some unknown cause, which has baffled the most successful and experienced growers. It is our intention to prepare a list of those sorts which have escaped, for the benefit of our readers; by this means we hope to ascertain which are the hardiest and most vigorous. We have filed a list from a grower who has lost upwards of a thousand plants since October, and we invite similar lists from those of our readers and friends who have had the good luck to preserve any Verbena plants alive. In Mr. J. Peacock's (Hough Green) collection—Velvet Cushion, Mont Blanc, Lord Raglan, De fiance, General Jackson, Pink Queen, Fort Lunter, Lord Craven, Beauty, Princess Alexandra, Grand Poul de Nieve, Purple King (has struggled hard through), Mrs. Woodroffe.—(*Cheshire Record*.)

WEST MIDDLESEX GARDENERS' MUTUAL PROTECTION SOCIETY.

WE have seen how the London mechanic has raised his position in spite of the opposition of his master, but what has been done for the gardener? I hailed with delight the rise of wages in nurseries, and it was hoped that the gentry or the proprietors of gardens would follow the example; but they have not done so. Surely it must be from want of consideration; for how can it be expected that young men will always be contented to live in a state of semi-starvation? It cannot be otherwise at the present rate of provisions. The prospect of an uncertain future has lost its effect. Young men are looking more and more to the time present, and it is sincerely to be hoped that something will be done to elevate their position. They ask not the wages of the mechanic; but surely they ought to receive as much as a bricklayer's labourer. But to keep more to the point, I will describe as briefly as possible what is being done for the benefit of the journeyman gardener.

There have been three meetings at the Workman's Hall, Portland Road, Notting Hill. The first of these took place on the 4th of December, 1865, Mr. Gardiner being in the chair, and the following resolutions were put to the meeting:—

1st, It is the opinion of this meeting that the time has arrived when an advance of wages ought to be made. 2nd, That a deputation be appointed to wait upon the employers to ask for the same. 3rd, That a committee be formed with a view to take into consideration the best means to form a society.

The second meeting took place on the 18th of December; there were upwards of 150 gardeners present. The Chairman (Mr. Burley) addressed the meeting, saying that it was a fact beyond contradiction that gardeners were not paid according to their services, and he said that he, as an employer and a nurseryman, would do all in his power to raise their position, and that he would thenceforward give £1 1s. per week to every man in his employment.

After several discussions the meeting came to this conclusion—viz., "That no journeyman, from the 1st of March, would work under £1 1s. per week."

The third meeting took place on the 5th of February, a large number being present. Mr. Burley (the chairman) commenced by reading the rules (which were framed previously by the Committee). The rules are these:—

1st, That this Society bear the name of "The West Middlesex Gardeners' Mutual Protection Society," and be composed of gardeners employed by nurserymen, those in gentlemen's establishments, and jobbing and market gardeners. 2nd, That the Society's object is to raise the journeyman gardener's pay to not less than 3s. 6d. per day. 3rd, That no one be admitted a member of the Society but through the introduction of two members. 4th, That a list of members be kept in the Hall, and a list of those who are out of employment, so that employers may apply to the Hall for such. 5th, That a Committee of not less than five meet at the Hall weekly (Monday evening, 8 p.m.), to transact the business of the Society. 6th, That each member shall pay 6d. on entering, and 2d. per week afterwards, to meet the expenses of the Society, and each member to have a printed copy of the rules. 7th, That all members are requested to meet at least once a-quarter. 8th, That a Secretary be appointed, who shall receive pay, the only officer of the Society who shall receive such. 9th, That a Treasurer be elected, who shall receive and pay all sums for the Society. 10th, That advertisements be inserted in the *Gardeners' Chronicle*, *JOURNAL OF HORTICULTURE*, and *West London Observer*, inviting employers to apply to Mr. Odell, Workman's Hall, Portland Road, Notting Hill, for competent gardeners.—J. W. B.

BOILERS.

I AM glad to see that the subject of boilers for heating horticultural buildings is being discussed in your columns. I have no doubt that it will tend to throw light upon the subject, and be the means of enabling the amateur and gardener to arrive at correct conclusions, detect the faults and failings on the one hand, and discover the advantages on the other, and then, after weighing the whole, to fix upon that form which will prove to be both durable and efficient.

Each kind of boiler, perhaps, has some advantage peculiar to itself, but it sometimes happens that these advantages are gained by sacrificing others of more importance. I have, as a gardener, had many years' experience with the most popular forms now in use. I have worked the old saddle, the cylinder, the conical, the upright and the horizontal tubular, the double-decker, and one called the mushroom in consequence of its shape somewhat resembling that fungus, and, last of all, I have had fixed one of those called the terminal saddle, which I see is now being advertised in your paper.

The general result of my experience leads me to confirm what McIntosh has previously said: "The more whimsical the form the greater the expense; the more intricate and complicated the more likely it is to get out of order, while such forms are not calculated to stand the wear and tear of those which are of more simple construction."

To judge rightly of the merits of any boiler it is necessary to have certain distinct ideas impressed on the mind; for instance, the amount of surface over the fire, which is of much greater importance than the surface exposed to the fire. The largest amount of heat ascends, and its greatest effect will always be produced on that part which is immediately over the fire.

The position and arrangement of the flues are seldom taken into account, but it is a matter of great importance. The flues should be so arranged as to prevent as much as possible the escape of heat into the chimney. The fact that heat will rise, quite convinces me that the opening for the flue should not be at or near the top of the boiler. If so, the heat and flame ascend to the highest point, then escape through the opening and are lost.

The easy access for cleaning-purposes to every part of the

boiler exposed to the fire is very important. This must be patent to every gardener, for when the iron is coated with soot very little effect can be produced upon it by the fire.

Then, simplicity of construction should be secured, for it best enables a boiler to bear the wear and tear of a hard winter's work, and yet remain sound and good.

Any one bearing in mind these four conditions will have a good guide for the selection of an efficient boiler.

For my own part I do not like the tubular boilers. I admit that they will heat a great length of piping, but that is only accomplished by a tremendous consumption of fuel. They are very wasteful; the furnace being formed of brickwork absorbs a great amount of heat, and the flame seems to glide up the vertical tubes without producing a proper effect, passes into the flue, and is lost. The conical is open to the same fault; the opening for the flue is just at the top, and I have seen the flame come out and reach nearly a yard up the chimney. The loss of heat must have been fearful. The cylinder has just the same faults as the above. The two-decker requires a strong fire, and a constant flame must be kept up to wrap round the lower part and come in contact with the top, otherwise it is ineffective. The mushroom is not worth further mention.

Among the many boilers which I have tried, I certainly prefer those of the saddle shape. This comes the nearest to my ideas of a good boiler, and, if properly set, is not easily beaten. If after three months' trial I am justified in giving an opinion, I should say that the terminal variety of saddle is a decided improvement on the old form. This is very simple, of great power, and very moderate in its consumption of fuel as compared with the amount of work done by it.—A HEAD GARDENER.

In your impression of the 6th inst. I observe that Mr. G. Cooper has expressed a desire for information as to the experience of those who may be possessed of tubular boilers. As he has referred to my name in connection with a few observations I made about three years ago relative to the merits of Clarke's water-jacket boiler, in justification of those observations I am glad to be able to affirm that my subsequent experience of its capabilities tends to justify the anticipations which I entertained as to its efficiency and durability. Its exemption from the peculiar fissure, which appears to be incidental to those tubular boilers instanced by Mr. Cooper, is calculated to render it a boiler of superior merit—that is, as regards non-frangibility.

As a preventive of soot or other matter accumulating on any portion of the boiler, I found that the simple application of an occasional extra brisk fire effectually prevented that evil, excepting in one instance, about two years ago, when I found it necessary to examine and scrape off a substance resembling coal-tar, which I attributed to the nature of the coal, in conjunction with the foul state of the flue which conveys the smoke along the back wall of one of the vineries, with the view of making up for the deficiency of hot-water piping in that house. I do not, however, absolutely advocate the system, as a more effectual draught is secured by conveying the flue vertically over the boiler. It also precludes the inconvenience of cleaning, and the dangers incidental to flues, crazy ones especially.

It is not my present purpose to discuss the comparative merits of boilers nor improvements on them—with one exception—that is, my objection to water-bars, the employment of which I believe to be wrong in principle, inasmuch as they tend to obstruct the thorough combustion of the fuel, owing to the rapid conduction of the metal; and, further, I believe they prevent the air supplying the oxygen necessary for combustion entering the fire as hot as possible; but the evil may be somewhat remedied by keeping the water-bars as clear of ashes as may be practicable, hence I doubt the advantage of water-bars.

At some future time I hope to be able to offer a few observations on the merits or demerits of another kind of boiler which it is in contemplation to employ here. In the meanwhile, like Mr. Cooper, I trust that others may be induced to favour us with their experience of boilers.—W. GARDNER.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The operations recommended here periodically cannot, perhaps, always be pursued with propriety at the precise period indicated; the position of the garden, as well as the nature of the soil, must be considered, and if these circumstances are unfavourable, they may be permitted, as exceptions, to modify the general rules. The preparation of the various quarters

designed for main crops must be persevered in whenever the soil is dry enough to admit of being trodden on without being too much consolidated. This is of great importance on heavy stiff soils, and those who have such to deal with should take advantage of every dry day that occurs. On such soils, too, it will be quite advisable to defer sowing main crops for a week, and even a fortnight; but on light dry soils the sooner the main crops are sown the better, because such soils are most liable to suffer from drought should it occur, and, therefore, the sooner the crops can be well established the better will they be able to resist its effects; if, on the contrary, the season is a wet one, they will still be in the best possible condition to profit by it. *Beans*, sow the main crops, regulating the quantity by the demand. *Cabbage*, make a first sowing of the true Drumhead Savoy; also, a small sowing of the true Grange's Early White Broccoli made now will come in useful by-and-by; sow another patch of early Cabbages. *Celery*, the first sowing must be pricked out as soon as it can be well handled, and another sowing made of both Red and White. *Cauliflowers*, prick out the young seedling plants, as also plants of Lettuces, either on a warm border or a gentle hotbed, and shelter them for a time with hoops and mats. *Cucumbers*, add fresh soil as the roots of the plants appear at the outside of the hill, lay it close to the side of the frame for a few days before it is required that it may become warm. *Kidney Beans*, if there are any in the vinery or Peach-house, keep them frequently syringed to prevent, if possible, the appearance of the red spider; if already attacked, the better plan will be to remove them to a pit or house where no injury can be done to other plants. *Onions*, the principal crops may now be sown, the Deptford, old Brown Globe, James's Keeping, White and Brown Spanish, are good sorts; sow them in beds 4 feet wide, and in drills 9 inches apart, and, if you can obtain it, sow some charred refuse along the drills previous to covering in. When the beds are raked smoothly over, and the surface is a little dry, pass a wooden roller over them several times, as Onions will bear a considerable amount of consolidation in the soil. *Peas*, sow the main crops of the summer sorts, together with a few of the later kinds. The ground on which Peas are sown comes in well for Celery. The rows, as advised, should be 6 feet apart; this distance might be increased with great advantage, and the intervening spaces sown with Spinach, early Turnips, Radishes, and Lettuces, all of which would come off in time for the Celery. *Parsley*, sow a good breadth of the best Curled, the finest is obtained by transplanting it at 1 foot apart on rich, deeply trenched soil. *Potatoes*, plant more early sorts, and reflect whether it would not be advisable, under existing circumstances, to plant both early and late varieties earlier than hitherto. Those who plant earliest will stand the best chance of ultimate success. We would also recommend whole tubers in preference to cut sets. Persevere in hoeing, forking, or otherwise surface-stirring among advancing crops.

FRUIT GARDEN.

Pruning should now be quite finished in every department, and whatever nailing is left undone must be completed immediately. See that newly-planted fruit trees are properly staked and mulched, and, after high winds, it is necessary to look round them, and press the earth gently round the base of the stems. All danger of very severe frost being over, Figs may have the coverings completely removed, and be neatly pruned and nailed; do not crowd them with wood.

FLOWER GARDEN.

The digging of flower-borders must now be commenced in good earnest; in performing which, use the fork in preference to the spade. All kinds of herbaceous plants may now be planted, either to fill up empty spaces or to make new plantations in borders which have undergone a course of preparation. Pay particular attention to the arrangement of these as regards height, colour, and succession of flower. Proceed with the planting of hardy Roses. If the plants be strong, prune their heads according to their classes, as advised last week; if weak, cut them back to two or three eyes, shorten all long and straggling roots, and prune away such as may be bruised or broken. If the ground has not been prepared as previously directed, we would recommend pits to be made, and to two pits give a wheelbarrowful of rotted dung and good loam well mixed. By all means avoid deep planting. Have a quantity of stakes and tarred twine close at hand, and stake each plant whether it be a dwarf or standard; many losses are incurred, or much injury sustained, when this is neglected. Continue the pruning and nailing of climbers, also the arranging and tying of such as are against trellises, verandahs, &c.

GREENHOUSE AND CONSERVATORY.

The Poinsettias done flowering in the conservatory should be removed to other houses at work to make nice wood from which cuttings may be made. The *Euphorbia jacquiniæflora*, too, may be removed to heat, but not pruned if cuttings be an object; they will break better without pruning, being liable to bleed. The routine here will now be a constant exchange with the other houses or forcing-pit. Nothing should be allowed to remain unless in blossom or in fine health. Let the heat be moderate. Secure, if possible, a small amount of atmospheric moisture without drip. Those who follow up the cultivation of Pelargoniums should have their plants duly attended to in regard to staking out, &c. They will bear shifting the moment the blossom-bud is formed in the terminal points. Water very moderately after shifting until the pot is half full of roots; those not shifted will take water freely. Epacrises, Heaths, and others of the more hardy plants in or coming into flower, should be kept near the openings for ventilation; while Roses and other forced flowers in the conservatory, and fresh from the forcing-pit, require the warmest end of the house, and ought to be kept free from currents of air. This is a good time to make memoranda of the best varieties of forced bulbs, especially Hyacinths and Tulips.

STOVE.

The fires should be kept sufficiently lively in the early part of the day to allow of a free circulation of air. Every leaf in the house should be dry for an hour or so at midday, after which period the air should be gradually withdrawn, and atmospheric moisture renewed. This treatment will be found to suit the majority of stove plants.

FORCING-PIT.

This is a good time for propagating many plants by cuttings, seeds, and grafting, and the forcing-pit is the best place for this work. Seedlings already up ought to be potted off as soon as they can be handled. Let every shelf and corner of this pit be filled with plants as others in flower are removed from it.

PITS AND FRAMES.

Those who have not yet attended to the propagation of plants for bedding out must now begin with all possible speed to put in cuttings of Geraniums, Petunias, Verbenas, Fuchsias, Salvia, &c., so as to have good plants for bedding out in May. Pay due attention to shading, watering, and to topping back weak and straggling shoots, so as to form robust bushy plants. They will give a greater amount of satisfaction when they come to be transferred from the pots to the flower garden, and will amply repay all the little extra care and trouble. Have any snails or slugs found snug quarters in this department? If so, they will do much mischief during the mild weather if you do not look for and destroy them as soon as possible.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Dm very little here as yet in the open ground, as our soil is still too wet to be dug or moved nicely. Proceeded with raking together a few tree leaves, which are very scarce this season. Placed a little old rough hay that we saved from some parts of the pleasure grounds over the heads of Broccoli coming in nicely. A few heads that were overlooked were injured in the sharp frosty mornings.

Ice.—The frost was severe enough in the mornings in the beginning of the week to have given employment for the iccart if the days had been dull; but the very bright sun following the frost dissipated all the ice that was formed in the previous night, so that we could collect none beyond what was needed for filling the receptacles for present use. In Mr. Robson's observations on storing ice, &c., there is much room for thought and inquiry. It often happens that theory and practice do not quite agree; so much so, that the result is very different from that which we should have expected from the general theory. We own that we have sometimes been non-plussed with ice-houses, some of the roughest and simplest keeping ice well, and others constructed with great care scarcely ever keeping the ice any length of time. There can be no doubt that moisture or vapour, considerably above the freezing point, melts ice very rapidly. We recently alluded to ice in wells sinking more rapidly after it had fallen below the level of the door-way. We may mention two facts as recollections of ice-houses. One house, by our own recommendation, and chiefly for sanitary purposes, was dug out of the side of a hill, former

chiefly of softish chalk stone. There was a drain from the bottom that prevented anything like stagnant water; but the rains trickling through and down the hill so moistened the chalk that the ice, amounting to twenty-five or thirty loads, well packed, was all gone by July. The place altogether was small. The circumstances of the benevolent gentleman did not warrant a large outlay; but it took very little labour to widen the place to take out more chalk, and as there was a lot of old studs, and turred boards from an old barn, fit only for firewood, with these the sides and top were covered, 1 foot from the chalk. Any holes were daubed-up with thick clay, mortar, and chopped straw, and, the door being left open, when all was tolerably dry a thin coating of hot tar was given to the old boards, and all was quite dry before winter. For several years the house was capable of keeping ice until January and February. We afterwards learned that when the boards would stand no longer the ice did not keep so well, though packed round with straw. The straw became damp, and then the ice melted, leaving only a cone in the centre. It was found that the top of the house, formed of the natural chalk, with a covering of earth and rough herbage on the surface, seldom showed signs of damp inside, whilst the side walls of chalk always became moist in the spring. It was suggested to run up inside a double-sparred fence of old hurdles, &c., with a space of 8 inches between the two sides of this fence, and this space was stuffed firmly with dry fern and straw, the inner fence being fully a foot from the wall. Here, again, the ice kept fairly when thus isolated from the damp wall. It would be well if any person disposed to try a hole in a chalk hill were first to make sure whether the chalk would remain dry in winter and spring.

The other fact came under our notice on our last visit to Trentham, when staying for the night at the admirable hotel at Stoke station. On going round the grounds of the hotel in the morning, admiring the fine sheet of water, and noticing a picturesque mound in the garden, the housekeeper informed us that it was their ice-house, that it had been made at a great expense, that due care had been taken to keep it dry, to ventilate it, &c., but that the ice could not be kept in it for any length of time in summer, and that a large sum was spent every year in obtaining ice from Liverpool and other places. We were very anxious to examine the house, but the time-table of the trains could not be trifled with, and as yet we have no more light on the subject, than just the idea that from the proximity of the fine piece of water, damp might have been the chief cause of the failure, and that a double-walled house, all above ground, with at least a foot between the walls, either left open or packed with dry sawdust, and a thick-thatched roof reaching nearly to the ground would have been more likely to have answered. As the subject is of some importance, it would be well if some of our gardening friends in the vicinity would ascertain if the ice-house at the hotel is still so far a failure, and if so try and trace the cause, as if we knew the cause of failure, or the remedy found effectual in such circumstances, it would be useful for future guidance.

Prepared an earth-pit for receiving as soon as possible some fermenting material for early Potatoes, &c. Gave air in sunshine, and when mild, to Potatoes in pots becoming ready for use, and to successions in frames. Did the same with young Radishes, Carrots, &c., protecting them at night with a little rough hay saved from the shrubby parts of the pleasure ground. Gave abundance of air to Peas under protection, as our ground is not fit to receive them out of doors, and we do not yet choose to turn out any of the dwarf Tom Thumb into the orchard-houses, where they did so well last year, because we are keeping these houses open night and day, when it is safe to do so, from the absence of wind, in order that the frosts may nip the trees a little, and keep them back. As yet we have only noticed a few buds of Peaches beginning to show colour, and we want none to open in these unheated houses for some time yet. Put some unused iron rails on the top of pots in the front of the Peach-house, covered them over with moss, and on these set a row of 12-inch pots, furnished with nice stubby plants of the Tom Thumb Pea, and when, some time hence, they are removed to the orchard-house to perfect the fruit, the same improvised shelf will come in for Strawberries or Kidney Beans, though we generally keep the latter out of our houses. Sowed more Kidney Beans in five-inch pots, to be ultimately planted out or transferred to larger pots. Had to shut up a cat in the Mushroom-house, for, after pretty well clearing it of snails and slugs, a colony of mice found the small sweet Mushrooms more palatable than any bait we could give them.

Kidney Beans, Cucumbers, &c., rejoiced in the sunshine that attended the frosty mornings. Cucumbers needed a little shading in the brightest hours of the clearest days, the sudden transition from cloudy foggy weather to clear sunshine affecting plants very much in proportion to the high temperature in which they are growing. Hence the importance of keeping the temperature as low as to be safe in dull weather, as heat without bright light leads more to mere expansion than addition of substance; and the thinner and more delicate the foliage, the less can it stand at once a sudden demand of evaporation in sunshine, and the roots cannot at once meet that sudden demand. A slight shade, or even a syringing overhead, is generally better in such circumstances than any root-deluging, as either will prevent an excess of evaporation until the reciprocal balance between roots and leaves is restored. For all tender plants in heat a slight shade is more important in these sudden changes from dull weather to bright, than at any other time.

Scorching.—In the middle of a fine Cucumber leaf on a plant growing in a pit, we noticed yesterday a piece about the size of a two-shilling-piece as thoroughly scorched as if a hot cinder had been laid on it, and it was some time before we could find out the cause. At last we found a blister on the glass, near the front of the sash, and a long way from the scorched leaf, so that from its position the one could have no influence on the other in the middle of summer, but on holding a pole in a line with the blister on the glass and the scorched piece of the leaf, we found the line to be identical in position with the rays from the sun a short time after noon. The blister being daubed with a little paint, will act no longer as a concentrating lens. Much of the cheap plate glass is well studded with these scars, and hence scorching and burning are often attributed to the wrong cause.

Went on with other forcing much the same as last week.
RATH GARDEN.

Vine borders.—We intended to have fresh-bordered a part at least of a viney, but found we could not obtain the necessary material in time, and, therefore, must defer it. Meanwhile scraped off the black exhausted soil from the surface. Gave a surfacing of nice fibry manure, and covered with litter to keep out the cold, placing the warmest next the new soil, and using a depth of about 15 inches altogether. We generally do this in the autumn, or at least much earlier; but as we do not mean to force much, the covering will do in the meantime. The buds are beginning to show from having been forced earlier previously. In the present case we could not help ourselves as to material, having had nothing on the border but a little stubble to keep frost out, and that is now laid on the surface of the litter again.

With Vine roots wholly out of doors we prefer covering the border, so as to secure a temperate heat in it before we begin to excite the buds in early forcing, and more especially if the roots are near the surface. We do not conclude, however, though we have had scores of hotbeds and frames or Vine borders, that there can be no danger from such hotbeds if not looked after. We know that heat from such beds goes down slowly, but it does go down—so much so that, perhaps, three times in the course of our lives we knew of roots of Vines being burned, and rendered useless, from a huge bed of fermenting material on the border. When much of this heating is done it is a good plan to have trial-sticks and thermometers at different depths in the border. In early forcing we have several times resorted to a mode which we first saw practised by Mr. Daniel Judd. Iron pipes were laid longitudinally along the border some 2 or 3 inches from the surface, with ends open outside the border, the openings being stuffed with a ball of moss or a plug. In this piping a thermometer was placed, fixed firmly to a long slender pole. On pulling out the pole so as to see the thermometer, you could always see the degree of heat at that depth from the surface. If that stood at from 70 to 73 there would be no danger, as from 8 to 12 inches deeper the heat would be reduced 5 or so. Where such attention cannot be given it is much safer even for early forcing, when practicable, to cover the borders early in the autumn with about 15 inches of dry litter or fern, and so as to throw off a good deal of the wet. If covers or canvas can be used for the latter purpose so much the better. This will secure a temperate heat in the border, with no danger of overheating. To secure such an advantage, however, from mere dry litter, the covering must be applied before the ground is cooled, so as to retain a portion of the summer heat—that is to say, put the covering on the border from the middle to the end of September.

Strawberries.—In sunny days drew a brush and a dry hand

over plants in bloom and setting. We had the most of our outstanding pots in an earth-pit, set on or plunged in leaves, and so that we could protect them with old sashes or hurdles, &c. We have escaped pretty well until the other night, when the mice began on the crowns in earnest, rendering from twenty to thirty pots useless. There being a considerable quantity of litter for covering, and the pots being set with tree leaves packed between them, it was very doubtful whether we could exterminate the mice before doing more damage, so that we have moved the plants out and set them in the orchard-house, without anything to protect the pots, but if the weather prove very severe, we can throw a little rough hay over them. The Strawberry plant will stand a good amount of cold, but plants in pots to be forced should never have the pots hard frozen, as it greatly injures the roots. If the pots are plunged they are not so apt to be injured. The above hint as to mice may be useful, especially if severe weather come. One gentleman told us last season, that out of eight hundred plants in pots fully five hundred were rendered useless by the nibblers in a few days. Both mice and rats will commence on the best and hardest crowns. Plants protected from frost and bad weather are more liable to be thus attacked than those grown in the open air.

Took in more plants into pits and houses, where room could be found for them near the glass. This is the only mode by which many of us can produce early Strawberries; and though good Strawberries are always useful and desirable, the make-shifts to secure them are often attended with a great amount of labour, and not unfrequently with injury to the permanent plants of the house. We have seen Strawberries taken from a series of shelves in an early Peach-house, that would have much more than paid the labour and fuel in forcing the house, without the value of a good crop of Peaches in addition; but though the shelves were removed before the Peaches began to ripen, the shade of the shelves in the earlier part of the season did nothing to add to the vigour and robustness of the trees. A good Strawberry-house, such as that at Enville, or the kind recommended by Mr. Ingram, is very desirable when it can be obtained. Such houses could be used for many purposes when the Strawberry season was over.

Orchard-houses.—Kept them open night and day when we could do so without dread of winds. The trees on the wall have been tied to the nail-studs, and most of those in pots have been staked and set in their places. Few buds as yet are showing signs of opening, and they will be early enough. It is easy to bring them on rapidly, if wanted, after the fruit is set, by early shutting up. An enthusiastic amateur told us the other day that his trees were coming into bloom. We would rather that rude March would show a little of the temper he was in before the blooms in unheated houses opened. If the weather should continue mild, or no more frost occur than we have had, he will be all right with his early-blooming trees. If a severe frost, say of 20° below freezing point, should come in March—and that has been the case in times gone by—the only safety for such trees would be a close, still atmosphere at night, and, if danger were apprehended, a few small charcoal stoves in the house. An Arnott's stove, a small flue, or even a hot-water pipe in such houses, will be useful in such an emergency, if used at no other time.

The first quiet dull day that we can spare the time, the trees will all be syringed with the sulphur-and-lime mixture alluded to the other week. Very often these precautions do away with being troubled with insects much during the season. Prevention in all such cases is ever better than cure. The way in which insects come to a place, or make their appearance, is often as inscrutable as the breaking out of the dreaded rinderpest. We recollect sometimes visiting two gardens about ten miles apart. In one you could scarcely go through, especially in the tropical houses, without getting mealy bug on your clothes if you brushed accidentally against the plants. The other garden was singularly free of this and of other insects. All at once the mealy bug appeared in this second garden too, although no new or fresh plant had been introduced for more than a twelvemonth. One or two young men had gone from the first to the second named garden in the course of the year as visitors, and it is possible they might, quite unintentionally, have carried a brood with them on their clothes.

The rough-growing Figs in a low house are scarcely forward enough yet to enable us to prune them, which pruning will chiefly consist in taking out the worst-placed and most barren of last year's shoots, and stopping with the thumb and finger nails, or a sharp knife, the terminal bud when it is from ½ to

1 inch in length. Went over trees in the Peach-houses, removing the foreright and other shoots, and merely stopping a number more, so as to give no sudden or severe check to the growing powers of the trees; we prefer removing these extra shoots at several times instead of at once. The fruit being set, we use a few evaporating-pans on the pipes now; but in the dull weather we use little fire heat, being content with an average temperature of from 50° at night to 55° during the day, with a rise of from 13° to 20° from sunshine in bright days after a little air has been given. When the day promised to be sunny after frost, put on no fire in the morning, and thus a minimum of cold air was only necessary to be admitted. There is nothing more trying to early-forced plants of all kinds than the meeting together of a fierce sun heat and a strong heat in the heating apparatus. Letting in a large amount of cold air under such circumstances subjects the plants to another extreme. Labour and cost may often be saved from a careful noting and forecasting of the weather, which most people can do pretty accurately at those places with which they are long and intimately acquainted.

ORNAMENTAL DEPARTMENT.

Much the same as last week. Little doing as yet out of doors.—R. F.

DEATH OF MR. ROBERT OSBORN.—We regret to have to announce the death, on Friday last, of Mr. Osborn, at the Fulham Nursery. He was in his 84th year.

COVENT GARDEN MARKET.—FEBRUARY 24.

SUPPLIES continue abundant, and the demand is good but not brisk. Importations from abroad are kept up, and consist of the same articles as mentioned in previous reports. Black Grapes consist almost entirely of Lady Downe's and Barbarossa. White, of Tokay, Trebbiano, and a few Muscats. Pears for the dessert are scarce and confined to Beurré de Rance and Easter Beurré; Apples to Cockle Pippin, Nonparcils, Golden Knob, Fear's Pippin, and one or two others. Of Asparagus there is a rather short supply; but Rhubarb and Sea-kale are plentiful. It is seldom there is any fluctuation in the price of Garlic, but the demand which has sprung up for it as a remedy for the cattle plague, has trebled the price and rendered it difficult to be had. Potatoes still pour in in large quantities, and there is a heavy stock on hand.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

RABBIT TRAP.—R. T. would be obliged by the description of a trap to catch rabbits. He finds Miles's vermin trap of no use for catching rabbits.

MISTLETOE (J. Fenwick).—The berries are ripe in December. February and March are the best months for sowing the seeds. They succeed best on the Apple tree. Your best chance for obtaining seed would be to apply to some one in Herefordshire, or Devonshire, the orchard districts.

COLONIAL CULTIVATION (A. Gardner).—The journal you mention must not be transferred to our columns. We will take an early opportunity to publish some information on the other subjects you mention.

MARKET GARDENING (Chester).—There is no doubt that "first-class fruit will sell well in London at the right time," but you must go to Covent Garden Market and arrange with some of the fruiterers there for its sale. If you could find a market for your produce near home, you would avoid risks and carriage expenses.

LEAN-TO GLAZED HOUSE (P.).—For your house, 45 feet by 12, a saddle-back boiler costing from £3 10s. to £4 would suit you, and from two to four rows of four-inch pipes, according as you merely wished to keep out frost, or to force moderately, or early.

ANGLE OF VINEYRY ROOF (E. C. Dymon).—For general purposes, and as combining most advantages, the roof at an angle of 45° would be best, then the height of the back wall above the front wall-plate would be the same as the width of the house. Such a house will do for Grapes at all seasons. Sir Joseph Paxton's plan answers very well if the ventilators between the sashes are in two or three pieces instead of one.

GROWING MEALY POTATOES.—Will "W. Ross, Herefordshire," be good enough to inform me when, and how, the manures named by him at page 128, are to be applied? The ground on which I might try them has, some of it, been manured. In naming "manure" gardens, does he mean vegetable or kitchen gardens. Also, the cost of the manure per acre, and does it retain its properties for more than one season?—R. G. H. "In reply to 'G. P.,' I do not give much importance to the fact of how the alkali is applied, provided a sufficient quantity be within the reach of the plant. If sown broadcast more is required, and the alkalis being very soluble, in a wet season they would soon be carried beyond the reach of the plants. Impressed with these views, I have used as much dung as available, and then when planting ordered a handful of the mixture (the alkalis named, with guano or superphosphate), to be placed between each set. The last two dry seasons I have found the alkalis, &c., not all dissolved when the Potatoes were raised, but enough to insure mealy Potatoes. Our stock of Flukes being nearly used up, I ordered that the Skerry Blue should be cooked. It is rather a coarse, round, deep-eyed Potato, but upon the table, two days ago, the Potatoes were as mealy, white, and fine as any Hiibernian could desire—I should say, perhaps, vegetarian, for I have for nearly twenty years avoided the use of flesh as an article of diet, and of all vegetables the Potato is my greatest friend; therefore, I have made it my study how to grow healthy, fine, mealy Potatoes. That I have succeeded is proved by the fact, that if I have any to sell the dealer near will give a much higher price for my Potatoes than for those of any one else; and in the dry autumn of 1843, my cart, loaded with fine Dalmaines, was run after as a striking sight by people who were taking up Potatoes not much larger than boys' marbles. To save further trouble, I may state that the alkalis at the prices named have been supplied to me by William Hunt & Sons, Lea Brook Alkali Works, Wednesbury, Staffordshire.—W. Ross."

PLANTS INFESTED WITH INSECTS (S. E. R.).—Neither on the *Ageratum* nor *Geranium* leaves is there any trace of insects beyond the after-effects of red spider on the former, and of thrips and red spider on the latter. The air of the house must be exceedingly dry and hot, and much too close. Give air daily in mild weather, and employ no fire heat except to keep out frost. A good syringing or two daily for a fortnight will make the *Ageratum* all right. Fill the house with tobacco smoke on two consecutive evenings, and syringe the plants in the morning. Be careful to have the foliage dry before fumigating the house.

CINERARIAS FOR BEDDING OUT (H. S. W.).—The seed, sown in the end of January in a greenhouse, may grow. It would have been better placed in a hotbed. When the rough leaves appear the seedlings should be pricked off an inch apart into pans, and when they fill these, pot them off into 48, or 44-inch, pots, and when established in these harden off, and finally plant out in beds of good rich soil early in June. If kept well supplied with water, and the surface mulched with an inch of rich compost in the beginning of July, they will, as we have proved, flower in autumn.

PLANTING (H. J. Jackson).—The nurseryman you name we consider quite trustworthy.

FLUELESS STOVE (Dalstonian).—There is no stove without a flue that can be used in a greenhouse without injuring the plants.

RICINUS—FERDINANDA EMINENS—YUCCA GLORIOSA—WIGANDIA CARACASANA SEED SOWING (Zeta).—The seed of all should now be sown in pots, or pans, well drained, and three-parts filled with a compost of turfy loam two-thirds and leaf mould one third, with a free admixture of sand. Sow the seeds thinly, and cover with a thickness of soil equal to their diameter. Give a gentle watering, and place the pots in a hotbed of 70°, and maintain an atmospheric temperature of from 60° to 65° by night. Keep the soil constantly moist but not wet, and when the plants appear admit air and keep near the glass to prevent their being drawn up. When sufficiently large to handle, pot them off singly in small pots and grow on in the hotbed, shifting them as they require it, and finally harden off and remove to the greenhouse. The *Ricinus* will be of sufficient strength by the end of May to plant out in sheltered situations in the flower garden; but we question whether the others will be sufficiently strong to plant out in the first year. They should be continued in the greenhouse until they are so, and planted out from May to October.

CUTTING-IN INDIAN-RUBBER TREES (S. S.).—You may cut back the trees as far as you like and they will shoot again, and now is a good time. We have cut them back and found no difficulty in respect of their bleeding. We do not know what will prevent their doing so.

WIRE NETTING TO EXCLUDE RABBITS (W. M. G.).—Netting 24 inches high is sufficient to keep rabbits from gardens so far as height is concerned, but they soon find or make a way under it. We have some netting 2 feet 6 inches high, and also some 2 feet, and the rabbits never jump over either height. The main point is to fix the wire so low that an inch or two may be covered with soil, for they soon scratch a way for themselves when the wire is a little above the surface; but when it is below this they try to make a way beneath the netting, but finding the wire they give up the attempt.

BOOKS (A. M. T.).—If you send twenty postage stamps and your address to our office, and order Keane's "In-door Gardening" you will have it sent free by post. It details the work to be done in the greenhouse each week in the year.

WEEDS ON GRAVEL WALK (F. H. J.).—The best plan would be to have the walks turned next month, picking them up and turning the surface down as deep as the gravel will allow; from 4 to 6 inches is a good depth. A good sowing would destroy the weeds; but if this were done in April they would re-appear by autumn, if not sooner. The chief cause of weeds appearing on walks is their becoming covered with soil on the surface. Walks should be turned at least every other year, and this will do more towards keeping them clean than continually disturbing the surface with a Dutch hoe, and much hand-weeding is saved. For further remarks on the destruction of weeds we refer you to what was said at page 151, in answer to another correspondent.

IPOMEA LEARNI PRUNING (J. Baylen).—The new shoots would start much more strongly if the old were cut down to within two or three eyes of the old wood or stem. Your plant having three or four stems, we should cut back two of these to two or three eyes, and reduce the others by one-third of their length.

GESNERAS POTTING (Idem).—The tubers, potted in March after having had a rest, would flower in September. We have them now finely in bloom, and as we wish to have them in bloom earlier next year, we shall withhold water altogether, and this you may do without injuring the roots. They will now be formed. The single-flowering *Hibiscus* most commonly met with is *Hibiscus ros-sinensis*.

HEPAROMA TULIPIFERUM CULTURE (H. N. B.).—Yours being a young plant it should be potted early in April, using a compost of three parts of sandy peat or heath mould, and fibry loam and silver sand each one part. Provide good drainage, and do not give a large shift. Water carefully for some time after pottin, giving a sprinkling of water through a fine syringe on sunny afternoons. Stop the shoots if the plant grow straggling, but not after June if it is to bloom in the following year. After May it would do better in a cold pit, tilting the lights back and front, and should be removed to the greenhouse in good time—say about the end of September, placing it near the front lights and not far from the glass, at all events with no creepers between it and the glass. It likes air, but as with all or most New Holland plants, cold frosty currents are prejudicial to it; and, therefore, in frosty weather it should be given at the back of the house. If your plant is old and showing flower, do not pot it until the bloom is over, after which it should be kept rather dry and cool for a fortnight, then cut it back pretty closely, leaving, however, enough of last year's shoots for new growths. Keep rather close, and when it has made new shoots a couple of inches long, pot it, picking away any old soil, but without injuring the fibres, and affording efficient drainage. Do not give a large shift, and pot with the neck of the plant rather high. After pottin keep close and shaded until the roots are working in the fresh soil, then gradually remove the shade and give more air. Slight shade may be given on bright days up to August, when air and light are necessary to ripen the wood well before winter. It blooms from the points of the shoots, and must not be stopped after June.

WOODLICE IN FERK CASE (H. N. B.).—Take some large sound Potatoes, cut them in two lengthwise, and with a knife scoop out in the centre, the cut part a cavity of from half to three-quarters of an inch. The pieces being laid on the flat or cut side, there will be a hollow into which the woodlice will find their way, and there they will remain till after daylight. The Potatoes thus prepared are to be laid within the case at night, and in the morning the woodlice will be found secreted in the hollow of the Potatoes, from which they may be scraped off into a basin of boiling water, or chickens will make short work of them. The baits will last a long time, and by perseverance in their use the case will be completely cleared of woodlice, or a small toad placed in it will soon effect the same object.

HELLEBORUS—REGONIAS FOR WINTER-FLOWERING (A. Lover of Winter Bloom).—Helleboms atrocubosus with purple flowers is a handsome species blooming in February and March. *H. purpurascens* has smaller flowers of a darker purple. We have not seen the variety to which you refer. Of *Regonias*, *Darwelliana* is excellent for winter; so are *nitida*, *incarnata*, and *parviflora*. *Manicata* and *hydrocotyliflora* are very serviceable for spring. They require the temperature of a stove or intermediate-house during the season of growth, but when in flower may be removed to the conservatory.

VINES IN A GREENHOUSE (G. M. F.).—You may manage three Vines in your small house, 11 feet by 7, two Black Hamburghs and one Royal Muscadine, planting one 2 feet from each end, and one in the centre. For such a house a border 4 or 5 feet wide would do. If you use pots we would have them on the back stage, but we decidedly prefer a border outside, and taking the stems through the front wall as you propose. If you thus establish three Vines in the house, they will interfere with your keeping many greenhouse plants there in summer; but you may keep your general collection there from the time the Grapes are cut and the leaves turn yellow, until the Vines break and begin to shade the house—say from October to May, if you do not force. The way to combine such a viney with a general collection of plants will appear shortly.

BACK NUMBERS (J. C.).—The Numbers can be had from our office if you enclose eleven postage stamps. Specify again the Numbers you require, and state your full direction.

VINES IN CHICKEN-HOUSE (B. J. of C.).—If we understand aright, the glazed house for your chickens will be 80 feet long, have a sloping roof of glass of 10 feet, resting against a wall at back, and a six-foot fence of wood in front. It will do very well for Grapes trained 15 inches from the glass; but it would be better still if the front were also partly glass. Of course, for chickens and Vines alike, you would have to secure ventilation. The Vines would do in boxes 2 feet square, and the same in depth, but why trouble yourself with boxes at all, when you can plant outside and take the stems of the Vines through the boarded wall? If the soil is light, add a little somewhat stiff loam if you can obtain it; if not, some rotten dung and lime, and some bruised boiled bones. If the soil is dry you need not trouble about draining, but it is safest to have a drain in front. You could have eight Vines—four Black Hamburghs, two Espérons, one Royal Muscadine, and one Buckland Sweetwater, or more Muscadines if you like a white Grape. A small stove might help the chickens in spring. Any of the nurserymen who advertise in our columns would supply you.

REMOVING OLD VINES (W. Sheridan).—We presume your employer has power to take up the vines next season. If so, and they can be lifted with care in October, and be taken and planted carefully at once, they will be better than young vines. If this cannot be done, then we would prefer good young vines. If you resolve on lifting them, then your proposed plan of treatment is very good—that is, taking the crop this year, but stumping-in or shortening all the shoots above the fruit, and bringing up one single shoot from the bottom, and cutting all but that shoot away at planting-time.

GREEN PEAS (J. G. P.).—The Peas you saw had been preserved through the winter. Those which are brought to the London markets from Algiers are worth about 10s. per peck, but are only fit for soup, and for that purpose not equal to those preserved in tins. The best Peas are now worth 20s. per quart.

PINERY (A. Burge).—We have published full particulars, with drawings, in "The Pine-Apple Manual." You can have it free by post from our office for thirty-two postage stamps.

KIDNEY BEANS' BLOSSOM FALLING (T. J.).—What are your dwarf Beans? If kidney beans, the temperature by day is rather too high in dull weather; but if all else is right, we should think that the dropping off of the blossoms must result from dryness at the roots. Our Beans do not drop a bloom until it is shovelled off by the young pod. Temperature at night from 55°, and by day from 60° to 65°, with 10° more in sunshine. Very rich heavy soil over-watered, will also sometimes cause them to drop their blooms prematurely. Of course, you do not mean dwarf garden

Beans, or Broad Beans, for none of them will stand anything worth the name of forcing, nor yet will they agree with a close atmosphere.

NAMES OF PLANTS (H. C. L.).—Your *Acacia* is *A. decurrans* var. *molissima*, a native of Van Diemen's Land, and may be called the Very-soft *Acacia*. The other is an *Eucalyptus*, or Gum tree, native of New Holland, but we cannot determine the species without seeing a flower. (*W. R. J.*)—The fruit-bearing *Acouba* is the common *A. japonica*. It never bore fruit until recently, because none but female plants were in this country. We believe your *Jasmine* is *Jasminum heterophyllum*; it is deciduous if grown against a wall, and may be, as you say, evergreen in a greenhouse. (*An Old Subscriber, Surrey.*)—We cannot usually name plants from seeds, but the scarlet black-tipped seed you enclosed is so well known as forming a necklace for children, that we have no difficulty. It is *Abrus precatorius*, a native of the West Indies (*J. Jones*).—Your *Calanthe* arrived in such a crushed condition, owing to the box having been smashed in passing through the post office, that though we endeavoured to compare it with the *Calanthe* you name, we could make nothing of it. (*W. S.*)—1, *Platynerium alaicorne*; 2, *Phlebodium aureum*; 3, *Pteris cretica*; 4, Probably *Pteris heterophylla*. (*D. D. M.*)—1, *Scindapsus pictus*; 2, *Nephridium*; 3, *Selaginella cæsia*; 4, *Aspidium molle*; 5, *Adiantum trapeziforme*; 8, *Phymatodes*; 9, Fruit of a *Clematis*; 10, *Erica carnea*. The others insufficient for identification. (*T. C. Hove*).—It is impossible to say what your plant is from the scrap sent. (*M. D.*)—1, *Asplenium dimorphum*; 2, *Adiantum macrophyllum*; 3, *Pellaea hastata*; 4, *Selaginella*; 5, too young.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

RAILWAY CHARGES.

ONCE more, then, on this subject. There are some who are said never to touch a subject without adorning it. At any rate this is not my present object, I wish not to adorn, but rather to annihilate; and really, although my first thoughts on the subject were penned somewhat doubtfully, these shall be written cheerfully and hopefully. I received a communication from the Honorary Secretary of the Poultry Club, that after their Rochdale Show he would be prepared to take up the subject of railway carriage. Doubtless, without any joke, we, exhibitors, all trust that the Club will not take it up without putting it down. Then the Club will have earned the good wishes of all exhibitors, and ought largely to increase its ranks. In my last, however, I wrote that independently of the Club's efforts, I thought that exhibitors collectively should endeavour to influence railway authorities, and I now suggest the following form of requisition to be signed by exhibitors and forwarded to the various Boards:—

"TO THE DIRECTORS OF _____ RAILWAY.

"Gentlemen,—We, the undersigned, being breeders of exhibition poultry, desire to bring the following facts under your notice:—

"1st. That poultry exhibitions have largely increased passenger traffic on railways.

"2nd. That all exhibitors cannot be successful, yet the expenses of entry are large, and the addition of railway carriage tends to diminish the number of exhibitors, and thus indirectly passenger traffic.

"3rd. That railway expenses form a very heavy item to exhibitors.

"4th. That in the case of a crate, or hamper, containing goods being returned 'empty,' the charge is merely nominal, although it cannot have added to the passenger traffic of the line.

"Lastly. That exhibitors consider that their poultry hampers, if not carried free on the return journey when unsold, should at most be charged only as 'empty,' and they believe that with an abolition of the return charge altogether railways would be gainers, as distant exhibitors would send more specimens, and, in consequence, probably attend themselves, whereas, now, they are often deterred by the double railway expenses.

"We, therefore, beg you will give the matter consideration, and give such orders that in future all poultry returning from exhibitions may be carried free.

"We are, Gentlemen, &c."

This, it appears to me, embodies the matter in as few words

as we can, but I throw this out merely as a suggestion, and it depends on exhibitors themselves whether such requisition would be successful. It requires to be, like that presented to me when I was a visionary "railway king," influentially signed.—Y. B. A. Z.

Provided the means are forthcoming, I should advise the printing of some fifty copies or more, with the names of those signing the requisition, which I am now quite ready to receive, if the requisition is considered to meet the circumstances of the case. One of these copies, with the printed signatures, I will then forward to the head quarters of every large railway company, requesting a reply, and the names of those responding favourably can at once be published in "our Journal," perhaps in "letters of gold."—Y. B. A. Z.

P.S.—I have only to add, that since the matter has been mooted some of our most successful exhibitors have expressed their willingness to assist—a proof, were any needed, of the fact that the grievance is deeply felt even by those who have been supposed to show successfully. It needs not much consideration to determine how the shoe must pinch the unsuccessful class.

The following breeders have communicated with me, and I shall be happy to add others, and will, as time serves, communicate with others.

- Viscountess Holmesdale, £1
- Sir St. George Gore, £1
- J. Rodbard Rodbard
- J. K. Fowler
- Charles Pease
- R. B. Postans, 10s. 6d.
- H. Beldon
- E. Pigeon, £1 paid
- G. Mann ng, 10s. 6d. paid *
- Rev. C. Spencer, 10s. 6d.
- Rev. J. Ellis
- Rev. J. G. A. Baker
- Rev. A. K. Cornwall
- Rev. W. Shaw, 10s. 6d. paid
- H. Lane

- "Cactus"
- John Rhodes
- Miss Milward
- Mrs. Pettatt, 10s. 6d. paid
- Mrs. Seamons
- Charles Cork, 10s. 6d.
- E. Shaw, 5s.
- F. P. Edwards
- H. Yardley, 10s. 6d.
- S. Lang, jun.
- C. Jennison
- F. King
- Capt. Heaton
- T. Stretch, 10s. 6d.
- Joseph Hinton, 10s. 6d. paid

Most of these have also signified their intention to help in the "sinews of war," but have not mentioned any amount. I must apologise to many for apparent neglect in not answering their queries. I feel I must do this chiefly through "our Journal" as a public print, for the time I am able to devote to the matter is but limited; still, now that we have set the wheel going, I hope we shall not let it stop till we have completed our work successfully.

* Guarantees £2.

Some have asked for what purpose the money is required. Well, I propose when we have decided on a form of requisition to print off a certain number with the names appended, acquainting the various companies that the authority to append such names is in my possession. Besides this, there will be the postage of the letters to various breeders, &c. Possibly, too, the amount would be sufficient to pay the expenses of any amongst us who would offer to form a deputation to the various leading offices. On this point it would be well to have a list of those who could give up the time to the purpose.

I have only to add, that as it has been St. Valentine's time of year, possibly some of the replies to me may have miscarried; and if any exhibitors are unnamed who have done so, they will kindly accept this explanation, and, I hope, will communicate with me again.—JOSEPH HIXTON (Y. B. A. Z.), *Hinton near Bath*.

INTER ALIA.

CONCERNING RAILWAY CHARGES.

I AM not fond of railing. I beg the "WILTSHIRE RECTOR'S" pardon for indulging in one of his veins, when I am about to forget another—namely, christian charity. I have something of the Game Bantam in me, and hence it may be supposed that the Rector's sermonettes on my favourites have tried my forbearance. The defence of pets is already, I perceive, in abler hands than mine, and, therefore, with this preliminary crow I will proceed to my main subject.

I say again I am not fond of railing, nor am I in poultry matters fond of the rail; but for three years I have been sorely tried, and I must now have my say. I live on the Great Eastern line, which may be deemed sufficient reason for my complaints, yet I do not think that this company in these matters is much worse than any other. For a long time I have grumbled in solitude, and now I am willing to go in with "Y. B. A. Z.," and all the letters of the alphabet, to bring about a change in railway charges, and the carriage of birds.

When I began to exhibit, about three years ago, a bird on his road to an exhibition was indeed a *rara avis* at our station. Now we have not only had a poultry show of our own, but on the eve of any great exhibition, and of many small ones, "the cock's shrill clarion" drowns not the "echoing horn," but the shrill whistle of the railway guard. By the way, our poultry show was a surprise, for we had not only a balance sheet, but actually a balance in hand—a nice little nest egg for this year.

Now to my main point—namely, railway charges. From our station, with some few exceptions, we are unable to prepay with certainty for the carriage of birds, although poultry shows very properly require this arrangement. In fact, until I made a great fuss about it, the prepayment was entirely refused, except to stations on the direct line. The reason of this is obvious—it saves trouble to the officials. I have known a basket of my birds prepaid to its destination, whilst within half an hour the same application was refused to another person, and the last hamper was only prepaid to London. Although, for the most part, I now have my baskets prepaid, yet the inaccuracy and uncertainty to which I am subjected involves me in endless trouble. For example, to take a few out of many similar instances, I sent four baskets of birds to the Poultry Club's Show at Rochdale. For these I paid 6s. at our station. On their return I was charged 7s. 10d. for three only of them. "I cannot prepay when I send to a friend who lives near Hitchin, in Hertfordshire, although he always prepays when he sends to me.

I prepaid to Fareham, in Hampshire, and to Chippenham, the year before last, when the receivers were charged with the carriage, which, however, was refunded in both cases.

I have on the day I write this a charge from our station for a basket which I wished to prepay, and sent to Chippenham on the 9th of August last. I cannot now ascertain whether the receiver has also paid that.

I have a charge from the Midland Railway now on my table, incurred during the last Wentworth Woodhouse Show.

Of the four baskets from Rochdale mentioned above, two of them of the same weight, and both of them marked distinctly *via* Peterborough, one came back by the London and North-Western Railway, with a charge of 3s. 6d., and the other by the Great Northern, charged 4s. 6d. A neighbour was involved in extra expense and trouble in a similar manner. I received my four baskets in the following order:—One basket on Wednesday night last (7th inst.), by the 9.50 train. My man was there to receive it. Another, for which by the way, I was not

charged at all, and for which probably some six or seven months hence I shall have to pay, came on the following morning by the 8.55 train. The two others, by different routes, both reached me by the 12.40 train on Thursday. I was put to the expense of a telegram, and the trouble of writing letters to the Secretary of the show, and I am instructed that although the railway company had been informed of what would be required, and that although every bird was at the station of the Lancashire and Yorkshire Railway by the afternoon of Tuesday, yet that they were left at the station a whole day for want of carriages and servants to dispatch them.

The neighbour to whom I have already alluded sent a pen of birds to Whitehaven Show, prepaid to London. In London it was met and then prepaid to Whitehaven. He received his prize money, less 3s. 2d. carriage. This, however, has been refunded.

Once more. At our station the carriage of parcels from the station was once contracted for by an individual, and then we had almost as many deliveries as trains. Now the company have, for reasons of their own, taken the matter into their own hands, and we have only two deliveries—namely, about 10 o'clock in the morning, and between 3 and 4 o'clock in the afternoon. I am bound to say that my birds are sent up frequently from the station by special porters; but this means a gratuity, which is not fair to others, and might become a mischievous custom.

With these few out of many instances which might be given, I think I have made out in my own case alone a sufficient ground of complaint against railways.

What I should wish to see, would be a fixed and uniform rate for exhibition poultry, higher than ordinary parcel rates, but not the exorbitant charges we have now; more carefulness in ascertaining the weights of baskets and birds, and in filling up the details of freight notes, which I always require as a receipt, and every facility of carriage offered by lines of railway on which shows are held, by which both the line and the town would derive even more advantage than they do now. I do not care for any half-price measures. I do not want my birds sent back from shows as empties, which last, from my experience, do not always reach their destination. I want a plain, straightforward, common-sense charge, uniform throughout the kingdom, known at every station, and as fair to the railway as to the exhibitor.

I must apologise for this lengthy communication, and its *inter alia* ramblings, but I cannot drive the "WILTSHIRE RECTOR" out of my head. I thought a little while ago he was on for chapters on Pigeons, and scarce books; but, no, he dropped that, and took to reporting shows, till finding himself at Birmingham, and feeling, I suppose, there, a very Malay of critics, he went into our poor little Game Bantams. Why did he do this just as I was being dunned for little railway bills incurred in August last, just as I had found out that I was paying a variety of prices for carriage, and just as my Game Bantams had been delayed at Rochdale for a whole day?—EGGERT.

GAME BANTAMS.

BEFORE answering "WILTSHIRE RECTOR'S" reply to my letter, published in your Journal of the 30th ult., I was anxious to see if others would take up the defence of the much-abused Game Bantams. I have not been disappointed; and am much obliged to "P." for his letter in your Journal of the 13th inst., and also to "W. F. E." for his in your last Number.

"WILTSHIRE RECTOR" judges the entire class of Game Bantams by a pen he has bred and others that he has seen in his own immediate neighbourhood, with the single Birmingham exception: is this fair? Like "W. F. E.," I wish he had not given them up. If he had kept them on and exhibited them, he would certainly not have written that "they are easy to breed good." He says, "In poultry, popularity rests upon two bases—usefulness and fancy; the former a permanent basis; the latter anything but permanent." Now, I should like to know in what respect his favourite Blacks and Sebrights are more useful than Game? From experience I say the latter are much better layers, and are infinitely better for the table than either of the former, and I have yet to learn that they are less courageous, or more given to ramble. Can "WILTSHIRE RECTOR" explain what else it is than fancy that makes any variety of exhibition poultry sell for the fancy prices we daily see and hear of? If ever the poultry fancy die out, fancy prices will die out too.

"WILTSHIRE RECTOR's" comparison with the tulip mania, as "P." very properly observes, has nothing to do with the Game Bantam question. In the latter a judge sees and knows what he is buying; in the former he did not. I had a large superfluous stock of birds at the beginning of last season, they met with a ready sale. If I had had twice the number I could easily have disposed of them; I could not supply half the demand. It is true the eggs of Game Bantams are very fertile, but that is the only sense in which "WILTSHIRE RECTOR," or any one else, can say they are easy to breed. With "P." and "W. F. E." I again aver that no variety of fowls is more difficult to breed than really first-class Game Bantams, be they Reds, Duckwings, or Piles.—GALLUS.

P.S.—Like "AUDI ALTERAM PARTEM" I visited the Poultry Club's Show at Rochdale. The room was much too small (as is Bingley Hall) for the number of pens that were crowded into it; but, nevertheless, especially when we know how hurriedly it was got up, like your first correspondent, I thought it "a very great success." If "AUDI ALTERAM PARTEM" had read your Journal he would easily have ascertained what steps the Poultry Club had taken to discover the perpetrator of the Pigeon outrage. I fervently hope the Poultry Club will again, ere long, "make themselves responsible for another Show."

"WILTSHIRE RECTOR" has received a letter from Mr. John Crossland, from which the following is extracted:—

"I quite agree with you respecting Game Bantams and their breeding. I believe I am one of the oldest breeders of them, and it is well known to all that if a man understands the breeding of Game fowls he can breed Game Bantams. I have bred them for upwards of twenty years, and I every year breed a large number of first-class birds, and supply many prize-takers in England. As a proof: if a breeder has a thoroughly good breed he has no need of a cross, (as although Bantams are required to be small, yet Game Bantams need not be so small as other kinds). From a single yard in Yorkshire there have been sold upwards of £180 worth of Game Bantams in twelve months, and the greatest part of these fowls were sold to our well-known exhibitors in the Game Bantam classes. The breeder has also taken himself, I see from this Journal, from December 1864 to December 1865, four silver cups, cup and second at Darlington 1864, cup at Thorne for two years, 1864 and 1865, cup and second at Darlington 1865, cup at Birmingham, given by subscribers, 1865. This breeder, I should say, has won about £30 in prize money. If this is not a proof that good Game Bantams can easily be produced, I am at a loss to know what is.

"If 'P.' go on crossing the feather of his birds he will never breed good ones. I have only crossed once in ten years, and I gave £5 5s. for the bird—first at Birmingham, first at Plymouth, and first at Liverpool.—JOHN CROSSLAND."

My plan in life is never to enter into any controversy, but openly to state my opinion, honestly formed, on any subject that lies in my way. If some others do not think as I do, very well—"doctors differ," that is all. On the other hand, if I see good reason to change my opinion I as openly aver the change; but my opinion is unchangeable in regard to the easiness of breeding Game Bantams. As "P." has slightly misapprehended me in one point, I will add a few words to the letter which Mr. Crossland was kind enough to send to me, which letter, coming from the great Yorkshire breeder of these fowls, ought to set the matter at rest. One word previously: it is a fact that comparatively few poultry fanciers thoroughly understand their birds, and these few become regularly first-prize-takers. Others equally fond of fowls, equally desirous of succeeding, and who often go to great expense in crossing and re-crossing, yet do not succeed, save occasionally, because they are not masters of the arts of breeding, rearing, and choosing. Thus many persons do not even send the best birds they possess to a show, they have a fancy for this one or that, and of course they fail; while if another eye has looked over their stock and chosen for, or with them, they have at once succeeded. Not only ladies do this, who are most apt to have undeserving favourites, but even gentlemen err in this way. It is very odd how an owner (I am not speaking of an adept), will sometimes overlook the best bird in his yard. These are two secrets in breeding and rearing which are not learnt in a day, and by some never learnt. Again, as to crossing strains—I know three of the first breeders, if not the three very first breeders, respectively of Spanish, Dorkings, and Light Brahmas—I put this question to each one of them, "How often do

you cross your strains?" The same answer came from each, "I dare not do it, when I have done so I have obtained worse birds, or only my own back again." First-class birds are known to a first-class eye; and, with first-class management and choosing, comes first-class success.

In regard to Game Bantams being easy to breed, I mean almost all their eggs are fertile, the hens are good sitters and mothers, and the chickens are hardy, and, if of a thoroughly good old-established strain, there will be a large proportion of good birds; on this point notice what Mr. Crossland says. This is not the case with some other varieties. Of course when I speak of easiness to breed first-class birds, I mean in proportion to some other sorts. Here "P." misapprehends me. I know in this world it is in everything easier to produce what is indifferent than what is good—a weed rather than a flower, or a tolerably good flower rather than a first-rate florist's flower.

There are good strains of Game Bantams about the country and also inferior ones, having coarse legs, spotted breasts, and much too Bantam-shaped to suit the name Game; but the number of Game Bantams appearing at our shows is a conclusive proof that they are easy to breed. I do trust, however, that other varieties of the Bantam, and also Polish and even Malay, will not cease to be exhibited. Again, I beg to state that I am not insensible to the beauty of these miniature Game fowls. I like to see General Tom Thumb and his party very well, but I should prefer looking upon ninety-nine well-formed and full-sized men to ninety-nine Tom Thumbs, and should consider the former to be of a great deal more use in the world. I regret I have unintentionally ruffled the feathers of some of our Game Bantam fanciers.—WILTSHIRE RECTOR.

SOUTHERN POULTRY SHOWS.

MAY I be permitted, Messrs. Editors, to endorse most heartily the grievance so well stated by your able and entertaining correspondent, our kindly friend, the "WILTSHIRE RECTOR?" It is wholly inexplicable why all the poultry shows, with very few exceptions, should be held, as my factotum, with doleful visage, expresses it, "up in Yorkshire and them parts." Really the list of shows which the "WILTSHIRE RECTOR" gives, however creditable to "canny Yorkshire," is a disgrace to us southerners. Why is not the list interspersed with the names of well-to-do towns and goodly cities in the south and west? Who is at fault? Surely, as Sam Weller put it, "Somebody ought to be wopped for this!" Are exhibitors to blame? I think not. Those of us who send a couple of hundred miles to Manchester or Rochdale would gladly rally round shows nearer home, offering so many advantages—less risk, less expense, a shorter absence of the birds from home, and a chance of seeing them in the exhibition pen, without encountering the difficulties and discomfort, so forcibly suggested by the "WILTSHIRE RECTOR," in the vain attempt to reach some Ultima Thule of the north. Does the blame rest, then, with managers of shows? Have we not men of pluck as well as men of knowledge in the south? Could we not encourage such men as Mr. Houghton to start a show by the promise of a guarantee fund? Must London and Sydenham shows of necessity be failures? Will these places fail to do what every Yorkshire market town—aye, and many a village—succeeds in doing year by year? Will not the Poultry Club give us a metropolitan show worthy of its authors? Such a show would meet with more support in the south, where no rival was at hand, than if held in Yorkshire, with other shows jostling it on every side. One more question I ask: Could not we southern exhibitors form an association after the model of the Pigeon Societies, to guarantee one good annual show either in town, or in some southern city which would receive the association with open arms—that is, with local organisation and a local fund?

As you have another correspondent who has lately been addressing you as "BRAHMA," and it is advisable to preserve our separate identities, I must ask you not to omit the latter half of my wonted signature—BRAHMA POOTRA.

DRAGON PIGEONS.

I HAVE but just seen, in your impression of the 6th inst., a letter headed as above from a correspondent signing himself "A DRAGON-BREEDER," and who states that his attention has been called to a letter, in your paper of December 19th, from Mr. John Percival, of Birmingham, relative to the judging of some of the Pigeon classes at the late Birmingham Show.

Now, in the first place, I beg to inform him that the letter referred to, signed "John Percivall," (through an error of the printer), was from myself, with my address as at foot, although no address appeared in print, so that how your correspondent arrived at the conclusion that the address was Birmingham I am at a loss to understand.

I am pleased to find your correspondent expresses his thanks for the information conveyed in my letter as to what a good Dragon should be. I am quite aware there are more who do not know than there are who do, and I cannot help thinking your correspondent is one of the first-mentioned, or he would at once discard what he terms the very handsome birds with white rumps that he has lately become possessed of, and which he says, but for the expression of my opinion, he should have been unable to obtain. I beg, however, to inform him that such very handsome birds may be bought in any quantity at 1s. 6d. or 2s. each. Perhaps he would not object to a few white feathers in the flight or tail, which, in my opinion, would not be any more objectionable than the white rump. I am glad to find your correspondent state that many fanciers have taken the hint conveyed in my letter, by discarding the white-rumped birds they previously possessed, such birds being comparatively worthless.

I cannot see any reason for explaining the distinctive properties between the Carrier and the Dragon, these birds being so entirely dissimilar as to be well understood by all really competent judges.

Your correspondent goes on to say that white-rumped Blue Dragons are better in most properties than those uniform in colour throughout. This opinion, however, is quite erroneous, as the strain I possess (blue-rumped), are matchless in colour and metallic lustre in the hackle, so striking as to elicit the admiration of all good judges who have seen them.

In answer to the inquiry as to whether I would discard white-rumped Owls, I reply, Most certainly; but as to Runts, Antwerps, and Blue Rocks, they all rank so low in the estimation of the fancier as to make it a matter of indifference whether they be white-rumped or not.

I am pleased to find after all that the pair of Blue Dragons I exhibited at Birmingham, which were highly commended, and which the following month I exhibited at Manchester, where the same two Judges officiated and awarded them the first prize, elicited your correspondent's special admiration at Birmingham, and compelled him to admit they were the best pair in the Show. The pair which took the second prize at Birmingham belonged to my brother Mr. John Percivall, of Harborne, and were entered in his name, so that your correspondent may now know to whom the birds really belonged.

Your correspondent admits that my complaint of not having the first prize awarded to me at Birmingham for Dragons was not without good cause, as he acknowledges they were the best pair in the Show. My complaint, on the contrary, that the first prize for Archangels was awarded to me, in consequence of their being two odd-eyed birds, was intended to show how very badly the prizes were awarded in this as well as in the Dragon class; badly matched for showing the Archangels were, I admit, but having lost one just before the Show, and having but the one pair left, I had no alternative but to send them.—JONES PERCIVALL, *Montpellier Road, Peckham Rye.*

CRYSTAL PALACE BIRD SHOW.

On Saturday week I went to the annual Bird Show at the Crystal Palace, and, by your kind permission, will make a few remarks on what I saw there. I have nothing to say against the judging in the classes for Clear and Buff Norwich Canaries, but if Mr. Welch's birds had been in time for competition Mr. Collinson would have run a good second with his. I likewise pass by the other Norwich classes (3, 4, and 5), and merely remark that they were good; but as to classes 6, 7, 8, 9, and 10, I can find better Belgians at any small public-house show in either Manchester, Oldham, Rochdale, or Stockport, than I saw there that day. The winner in the Crested or any other variety class (10), ought to have been disqualified at the very beginning, for he had a split crest, and all fanciers know that on account of that he ought "not to be admitted as a prize bird." The owner only sent him to sell, and was certainly surprised when he saw the award, as he never expected it. In classes 11 and 12, respectively for London Fancy Jonque and Mealy, there was not a perfect bird certainly, but London Fancies are hard to meet with very good. Class 13, German or

any variety, except Norwich or Belgian, was fair; but 14 and 15, Lizards, were bad, bad, bad. There was hardly a fair bird in either class, and light-coloured legs, feet, and beaks, run caps, white-tipped wings and tails, and washy colours, seemed to be the order of the day. Some of the Silver birds looked as if they had been in a snow-storm, their spangling was all indistinct and blurred. About classes 16 and 17, Jonque Cinnamon and Buff Cinnamon, I have nothing good, bad, or indifferent to say. Classes 18 and 19, Jonque and Mealy Goldfinch Mules, were capital—very good indeed; but now let me ask, What are the rules for judging Mules? One Judge advocates a bird as like the Canary as possible, another man puts an evenly-marked bird first, a bird having the properties of both parents—which is the sort we are to breed? Both these Mule classes were good—very good indeed. Why was the Linnet Mule class struck out this year? Siskin and Greenfinch Mules, &c., ought not to be mixed up with Linnet Mules—they have no chance. Class 21 (six Norwich Canaries in one cage), was capital; 22, (the same number of Belgians), good; 23, (six Golden-spangled Lizards), bad; and 24, (six Goldfinch Mules) first-rate. Now, this Show is an annual treat, but would be better, greater, more successful, if, in my humble opinion, the following ideas, which I respectfully submit to the consideration of the Managers of the Show, were carried out:—

Firstly, let us have an extra Judge for Canaries—three instead of two; let one of these three retire every year by rotation, so that each year there may be one fresh man among the three. Secondly, take away the prizes for Magpies, Tillarks, and Chaffinches, and give the money as a prize for the best collection of Foreign birds in one cage. Thirdly, make separate classes for Clear and Marked Mules, both Jonque and Mealy; and, lastly, do let us have a standard of excellence to breed up to just as the Poultry Club have. I can name lots of men competent to draw one up. Messrs. Moore, Willmore, Goodwin, Barnesby, (of Derby); Carnally and Varley (of Nottingham); Hawkins, &c., including a few well-known amateurs, might be asked to state their views on the subject.—HENRY BEDWELL.

THE BIRMINGHAM COLUMBIAN SOCIETY.

BIRMINGHAM has long been noted for the excellence of its Pigeons, many breeders of high standing residing in the vicinity; but until Wednesday last the midland metropolis never possessed its Columbian Society. A few of the most ardent breeders of Pigeons in that neighbourhood, however, thought it most expedient to form such a Society, at which friendly discussion on the merits of their respective birds might take place at given short intervals, and an occasional exhibition be held to still further test the perfection of the Pigeons belonging to the respective members of the Society. The energy of the promoters of this scheme, and the almost universal support of all who were solicited, resulted in the gathering together of seventy pens of such Pigeons as would form a great acquisition to the best of our long-established Pigeon exhibitions. It must be borne in mind that only a single month has elapsed since the idea was first promulgated, and any one who attended this first meeting must have been quite taken by surprise to find the whole collection so good, that not a single individual pen could be selected from the numerous classes exhibited.

The Show took place in a large club-room at the rear of the Ship Inn, Steelhouse Lane, Birmingham, in an exceedingly well-lighted structure on the ground floor, and of most comfortable temperature. The owners of the very valuable birds executed everything that was required by their own especial handiwork. The show-pens were faultless, the condition of the birds equally so, and the attendance of visitors (entirely by private invitation-cards, for no money was taken at the doors), was remarkably good. The *Carriers* were especially good classes, the sexes forming two different competitions. The rivalry in both *Carriers* and *Dragons* was extreme, causing a great deal of friendly banter to take place among the various competitors during the last month, and, as the sequel proved, the struggle for superiority was so closely contested, that even the unsuccessful birds could have easily taken premiums at the generality of shows. The *Intercept* class was certainly better than has ever yet been witnessed in the locality; and the "Variety class" was an exhibition in itself. Black Swallows, Red Swallows, Spots, Brunswicks, and Satinets being all represented by specimens in condition so completely faultless, as to elicit the warmest expression of approbation among those by whom the "Toy" varieties are especially objects of admiration.

This first meeting was so exceedingly well conducted, that many new names were added to the list of members, and we understand it is now proposed to receive members from any part of the kingdom, the only restriction on future exhibitors being that they must be enrolled members of the Birmingham Columbian Society, and that all specimens of Pigeons must be the absolute property of those who may exhibit them. A show of birds bred exclusively in 1866 will take place in autumn, and it is anticipated such a collection will be brought to-

gether on that occasion as will still further add to the well-won reputation of this, at present, infant Society.

CARRIER (Cocks).—First and Extra Prize, * Messrs. Dawson & Walker. Second, — Allsup. Highly Commended, F. F. Foster. Commended, F. F. Foster. *Hens.*—First, Extra, and Third, Messrs. Dawson & Walker. Second, F. F. Foster.

TUMBLERS (Short-faced).—Prize and Highly Commended, H. Yardley. **TUMBLERS (Long-faced).—**Prize, F. F. Foster. Highly Commended, — Careless.

OWLS, NUNS, TURBITS, AND ARCHANGELS.—First, Extra, and Second, + H. Yardley (Owls and Nuns). Extra Prize, — 3 Mills, (Turbits). Highly Commended, H. Yardley (Archangels); — Mills (Turbits); — Cutler (Owls).

POWTERS.—First and Second, F. F. Foster. **DRAGONS.—**First and Extra Prize, ** — Ludlow. Second, H. Yardley. **THIRD, C. BARNES.** Highly Commended, H. Yardley.

BARBS.—First, Extra, and Second, H. Yardley. **JACOBINES.—**Prize, H. Yardley.

ANTWERPS.—First, H. Yardley. Second, — Ludlow. Highly Commended, H. Yardley. *Cocks.*—First and Third, — Dawson. Second, C. Barnes. Highly Commended, — Ludlow; C. Barnes.

ANY OTHER VARIETY.—First and Second, H. Yardley (Satinettes and Black Swallows). Highly Commended, H. Yardley (Red Swallows, Spots, Brunswicks); M. Noye (Satinettes.)

The Judges were Edward Hewitt, Esq., of Sparkbrook, near Birmingham, and Thomas Hales, Esq., of Handsworth, near Birmingham.

APIARIAN NOTES.

(Continued from page 136.)

Nos. 6 and 8.—Both were supered and worked well, and both threw off prime and second swarms, leaving large supers with combs begun.

No. 9.—A large flat-topped straw hive, from which a nice super of about 35 lbs. was obtained.

No. 10.—A hybridised Ligurian stock, with very prolific queen, used all the summer for recruiting-purposes. Brood and other combs were incessantly removed for the building-up of small artificial swarms into populous stocks; yet the hive is now, after having been submitted to all these drawbacks, a tolerably strong and prosperous stock. These hybrid Ligurian queens do breed immensely, particularly if forced in the manner just quoted.

No. 11.—A large-sized octagon box hive. An octagon super was put on; when partly filled it was deepened by being lifted on a second super having no top or bars. The hive was crammed with bees, which constantly threatened to swarm, royal cells being visible close to the back window. No swarm, however, went off, and a fine box of honey was removed in August.

No. 12.—A large frame hive, which was tenanted by the doubled swarms from Nos. 8 and 14 on May 30th. On June 5th the bees had done so well, and seemed so pressed for want of accommodation, that I gave them a large square bar-box super, having a few combs partially made. An eke being soon required, the super was raised on it on the 21st of June, and removed in August with 25 lbs. of pure honeycomb.

No. 13.—A second swarm hived in a seven-framed box, with a comb or two added. Nine days subsequently the queen was taken away, and a sealed Ligurian royal cell inserted. This, after a few days, was found to be torn open, and other Ligurian cells were substituted. The queen, which in due time was raised, proved to be a very dark one, and the hive was eventually broken up.

No. 14.—This is about the best stock I ever possessed. Originally an artificial swarm in 1862, at the head of which I placed a splendid Ligurian queen, kindly given to me by Mr. Woodbury, it has almost ever since maintained the first position in my apiary. At the end of March, 1863, as I find in my note-book, "No. 14. Bees attacked by dysentery; not populous; a few eggs laid; interior quite dry." I therefore did not expect much from the hive; but, from this date, the extraordinary breeding powers of the queen soon transformed it into one of the most populous of my stocks.

In 1863, honey obtained in one super,	50 lbs.
" 1864,	75 lbs.
" 1865, in two supers,	55 lbs.

180 lbs.

In the three years there was obtained an average of 60 lbs., without a cell of brood or pollen mixed with it. In addition to the 55 lbs. yielded by it last summer, the hive threw off a very fine swarm, having at its head the original Ligurian queen of 1862. The super was then two-thirds completed, and I at first feared that there was no hope of its being filled; but

* The Extra Prize, a Gold Seal and Key, for Cuck Carriers, being won by the donor of it, Mr. Dawson, it was by that gentleman's wish, transferred to the second-prize pen.

** A Gold Seal Pin.

† An electro-plated Sugar Basin.

** An electro-plated Marmalade.

the bees in a week's time appeared as numerous as before, and work progressed so rapidly that one of the supers was completely filled and sealed by the 15th of June. It weighed 35 lbs. nett., and was exhibited at our horticultural exhibition on the 23rd, gaining a first prize. It was subsequently taken down by Messrs. Neighbour to the Royal Agricultural Show at Plymouth, where also it was greatly admired. A second super was removed in August, containing 20 lbs. nett. The swarm which issued from No. 14 united itself, as has already been told, to one from No. 8, therefore I do not know whether the old queen is still to be numbered among the living, as she with her subjects first took up her quarters in a Stewarton hive filled with combs, in which inspection is difficult, and what became of her in the subsequent changes I had no means of ascertaining.

No. 15.—A nucleus, or diminutive artificial swarm, with Ligurian royal cells formed in the summer, gradually built up by the addition of brood-combs into a nice stock in a large frame hive. The queen proves to be hybridised.

No. 16.—Exactly similar to No. 15. Was presented to a clerical friend, and has by him been built up into an enormously strong colony.

No. 17.—Old-established stock in large frame hive. Became very populous. A fine super of more than 30 lbs. weight obtained from it.

No. 18.—My purest Ligurian stock; the bees are beautifully marked Italians. At the early spring inspection this stock, although only a small artificial swarm made late in the previous autumn, contained more brood and eggs than any other inspected. A very large swarm was thrown off on the 29th of May. After this, brood-combs and royal cells were removed to raise several artificial swarms. In addition to, or in spite of, this deprivation, it swarmed again on the 9th of June; but the bees returned. I took out the combs and quickly discovered a poor dark-looking queen at liberty, the other royal cells being fortunately untouched. Hoping that amongst these there might be a prur-looking specimen of a Ligurian, I at once destroyed this princess that had probably led off the swarm. On the 11th the hive again swarmed; this time all royal cells remaining were cut out, and the swarm forcibly returned to the stock. After this no further attempt at swarming took place, the hive being, considering its losses, tolerably well filled with combs and bees.

No. 20.—A prosperous hive in spring, to which were united the bees and brood-combs of an adjoining hive as previously related. A nice super was taken off.

Nos. 21, 22, and 23 have been fine stocks, and have collected a considerable quantity of honey in supers.

No. 24.—Artificial swarm, made June 14th. Afterwards broken up, and brood-combs used for strengthening another swarm.

No. 25.—A small second swarm of Ligurians was kindly sent to me by a friend in the north of England. This I have strengthened by brood-combs and liberal feeding, and it is now a very fair-conditioned stock.

My honey harvest, owing to the disposition manifested by the bees of a great number of the hives to swarm, has not been so good as it would otherwise have been, or as it was in 1864. Altogether, my favourites gave me in supers 230 lbs. of honey-combs. The honey-gathering suddenly dropped off about the 23rd of June, leaving most of the supers uncompleted, having a very large quantity of partially filled and unsealed combs. The supers being allowed to remain on in the hope of a return of the honey weather, the unsealed honey was almost all removed by the bees. I have little doubt that if the profuse secretion of honey in the flowers previously existing had continued but one week longer, more than 400 lbs. of super honey would have fallen to my share.

I do not lay claim to having had a very successful season; but having in bygone years periodically given the details of my apiarian doings, I think it may be useful also to have to record a partial failure in the results which might have been anticipated, considering the number of hives kept and the profuse secretion of honey which, at one period of the summer, prevailed. It will be seen by referring to the first part of this account that, after the union of the diseased stocks, I commenced operations for the summer with fifteen hives. Eight only of these afforded supers, and one super was taken from the doubled swarm. The failure of the remaining stocks in giving supplies of honey was attributable to their throwing off natural swarms, or, in a few cases, to their resources being applied to making or strengthening artificial swarms. Unfortunately, I have to record the loss of more swarms than I have ever before experienced. My hives are now kept in two apiaries,

consequently I have to trust much to the supervision of others. It so happened in several instances, that when the bees chose to swarm, most provokingly no one was at hand; the disaster being discovered only when an evening inspection made the fact but too manifest.

I have, therefore, to acknowledge disappointment on two points. I have usually been most successful in preserving all, or nearly all, my stock hives through the winter, and have recorded that fact in foregoing Numbers of this Journal. This winter several hives succumbed to, or were purposely broken up in consequence of disease. Then again, with regard to unwished-for swarms, I have generally had but little reason to complain of my super-working colonies causing much trouble on that account. If swarms have issued under such circumstances, I have usually accepted them as a boon, though not, perhaps, what would have been desired, removing the partially-filled supers to be completed by other old stocks, or by the swarms. This season, however, I was doomed to misfortune in the loss of many swarms from my best hives, notwithstanding that sufficient super accommodation had been afforded them.—S. BEVAN FOX, *Exeter*.

DRIVING BEES WITHOUT REVERSING THE HIVE.

I SEE that you want the evidence of a third party on the plan of driving bees upwards. Well, I am this third party, so be not afraid, brother Devonshire, although I did not see what was said at the time, as I have only taken in "our Journal" during the last two years. What an age and world we live in! Some jeering, some sympathising, some feeding their bees with mutton chops, others with turkey drumsticks, and I was told while I was in Oxfordshire that they fed them there with treacle rolls—that is, they mix up flour and treacle together. But stop: this is not driving bees upwards. Well, in 1861 I tried to drive an old stock that was in a straw hive, and, as there was only a two-inch hole in the top of the hive, I failed. In 1864 I tried again, and this time all right; I had then a box hive which for some reason I could not turn up; but I wanted the bees out, and I had them out. There was a three-inch hole in the top, so I lifted the hive, and out into the garden I went (no use to be afraid), opened the hole, put on a glass super, and drummed until the super was full; I then shipped a sheet of tin between the box and super, put the latter with the bees on an empty hive, drew the divider, and all was right.—A DUCKS BEE-KEEPER.

[We do not mind the trouble you speak of, but, on the contrary, shall always be glad to hear from you.]

DROPSY IN BEES.

WHEN "A DEVONSHIRE BEE-KEEPER" first hinted that he had experienced a new disease amongst his bees, I must confess I was a little perplexed, thinking and hoping that he was mistaken, and that it would turn out little more than an advanced stage of what has already been termed dysentery. When, however, he explained its nature, it flashed across me that I had had a similar case in the preceding year in a weak colony, and in which all succumbed to the disease save the queen, which I gave to another hive; but a few days afterwards I found her abandoning the hive in a weak state, and much swollen. This case was allowed at the time to pass unobserved, and now I regret to say that another instance came under my observation only a few days since, in which I have to add to my obituary the loss of another queen from dropsy. The hive in which it took place was at the time in good condition in every respect, being quite dry, well ventilated, and well stored, and to all appearance a perfectly healthy stock, although it was the one mentioned some time since as breeding drones and workers successively. I happened to be taking a cursory glance at my hives, when, seeing something unusually large on the alighting-board, I stepped forward, and found it to be the queen in a weak state, and much swollen. I took her in my hand, and tried to reanimate her, but in vain. I next endeavoured by gentle pressure to expel the accumulated water, but she did not survive the operation. In this case the queen and one worker are as yet the only victims. I may now say with certainty that the misfortunes which have befallen the apiary of "A DEVONSHIRE BEE-KEEPER," have made themselves no less conspicuous in that of—A LANARSHIRE-BEE-KEEPER.

OUR LETTER BOX.

DEFICIENCY OF EGGS (M. T. W.).—Your average (one daily from seven-teen hens and pullets), is a bad one, but far better than our own. We have been at a loss to account for between two and three hundred hens producing only from twelve to sixteen eggs daily—sometimes less, never more. We are obliged at last to seek for the reason that makes young, well fed, and healthy fowls temporarily barren; and having exhausted our knowledge and observation, we fall back on that inflexible shield and resource—the weather. Many weeks of endless rains and tempests have altered the surface of the earth, and deprived fowls of some essentials to their health and comfort, and the result has been detrimental to their fertility. Complaints of this nature will speedily disappear when the fine weather sets in. When? We must, however, warn you against one thing—if in the winter you have one out of four fowls laying every day, you must not be dissatisfied. You will never have April laying in January.

POULTRY-YARD (Subscriber).—Your question requires to be more explicit. Our answer would be another question—What breed do you intend to keep? 110 Brahmas, Cochins, or Spanish should have at least an acre and a half; if more, so much the better. The same number of Dorkings should have a farmyard if possible; failing that, one in which stable-dung, &c., is deposited, and they would require at least four acres for a run. We should consider a farmyard in which farm operations were continually carried on, containing an acre, and three acres of grass run, as better for a number of Dorkings than six acres of plain grass. We believe stable-dung to be almost excellent for poultry. Bailly, Mount Street, Grosvenor Square, will send you estimates, on application, for any number or description of fowls. The lighter your houses are the better for their tenants. They should not be less than 10 feet in height. 110 fowls should have 40 feet in length and 25 in breadth. Such a number of fowls should have the space divided in three—it is better for them; and where so many are kept no ceiling is necessary, it is only robbing the birds of a certain amount of air. If the house were divided into three, and if its height were 10 feet, the partitions should not be higher than seven. The incubator will be advertised next week.

DORKINGS' COMBS FALLING OVER (Coloured Dorking).—You are over-feeding. If a number of young Dorking cocks are put up to fatten, all having straight combs, these will, as soon as the food tells upon them, all fall over. Over-feeding spoils all real condition in every point, the feathers soften, the comb drops, and the birds become listless. Begin to alter to-morrow when the fowls are released for the day; or, if they go in and out as they please, when they are fed, give them a scanty meal of whole barley; at mid-day give them ground oats or barley mixed with water, and at night some whole corn. You may give them bread and ale in very cold or unkind weather, kitchen scraps when you please, not as an extraneous, but as a substitute for one of the others; no peas or pean-ut; above all, no hemp-seed, which we believe to be the cause of all the evil. Kock-salt is not necessary, nor are we aware that it is useful to fowls. White comb shows want of condition. Compound sulphur ointment will cure it. We do not know the cause of out-growing spurs, but we would not breed from a cock that had them. Do not be disturbed if your fowls appear restless under this regime. It will be the sign of returning health and strength.

CROSS BETWEEN BRAHMAS AND HAMBURGS (L. T. P.).—We do not like your cross. Both breeds are good layers; no barn can come to the egg from the cross; but the Hamburg does not sit, while the Brahma is a good sitter. You might by the cross make two had sitters in the room of one good one.

POULTRY IN SMALL SPACE (A Beginner).—We recommend you the Brahma Pouter as the hardiest bird and most prolific in confinement. You may in the space you name (25 feet by 16 feet, besides a roosting-house), keep fourteen hens and three cocks. They will lay well and keep in perfect health, with a little painstaking in providing them with large sods of growing grass from time to time, with occasional lettuce, cabbages when nothing else is to be had, a barrowload of road grit, and a bushel of bricklayer's rubbish. Mr. Bailly's address is 113, Mount Street, Grosvenor Square, London, W. Ground oats mean the whole corn entirely ground, and pulverised so fine that it mixes as well as though the bran had been removed from it. It is made principally in Sussex.

MOVABLE HEN-HOUSE (T. Short).—We have not published a drawing of one, but it is briefly described in the "Poultry-keeper's Manual," published at our office. There are several at Linton Park.

GAFES (J. Becker).—Give each chicken a piece of camphor daily the size of a small pea. Put also a lump of camphor into their water-trough. In the "Poultry-keeper's Manual," published at our office, the remedies for all poultry maladies are detailed.

PIE ON CHICKEN'S TONGUE (R. C. B.).—The horny substance you enclosed was nothing more than the usual covering of the point of a chicken's tongue. It is painful to the bird to have it removed, and certainly of no effect as a sanitary measure.

BLUE ANDALUSIANS (G. H.).—They are a large variety of Spanish with slate-colored plumage. They lay as large eggs as any other variety, their eggs weighing from 31 to 37 ozs. You will find them fully described in the "Poultry-keeper's Manual," published at our office.

SPANISH HEN (A. O. C.).—Your hen going on to the nest and not laying, intimates that her egg-organs are deranged. She is probably too fat, and the egg-passage obstructed. Give her a dessert-spoonful of castor oil and a pill containing a grain of calomel and one-twelfth of a grain of tartar emetic every second day for a week. Feed chiefly on boiled potatoes, with very little barley meal and plenty of green food, especially lettuce leaves.

PIGEONS (J. E. B.).—We have published such a volume, "The Pigeon Book," by E. P. Brent. You can have it, free by post, from our office for twenty postage stamps.

PARROTS (J. B. E.).—Brass cages are not injurious to Parrots unless verdigris be allowed to accumulate on the wires. There is no work on their management.

USING STOCKS (W. H. P. Oxford).—If you decide upon uniting your two weak colonies, March will be a good time for performing the operation. With common hives we know no better mode of proceeding than that described in page 39 of the fifth edition of "Bee-keeping for the Many," and as it is possible that one colony may be queenless, we should make no attempt to remove the driven queen, but leave the bees to settle this matter in their own way. There is, of course, a certain or, rather, uncertain degree of risk in all these operations.

RATS (G. H. G.).—The most effectual mode of driving them away is to ferret them, and then to pour gas tar into their holes.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 49.7°; and its night temperature 32.1°. The greatest heat was 67°, on the 10th, 1836; and 12th, 1841; and the lowest cold 7°, on the 10th, 1847. The greatest fall of rain was 0.70 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

A FEW GOOD ANNUALS.

It would seem that annuals, after experiencing several changes of public opinion, are again likely to come into favour. Some of this very extensive class of

plants have always been held in high estimation, others not so much as they deserve, many are of little value for decorative purposes, and every year new ones make their appearance. Thus the lists of the seedsmen are swelled to such a degree that they would become bewildering were it not for the descriptions given of the plants enumerated; but such notices are hardly sufficient, and the amateur finds himself in a difficulty when he undertakes the task of selecting twenty species out of a list of as many hundreds. In endeavouring to do this, although he may recognise some familiar acquaintances among the names presented to him, he not unlikely, and very properly too, wishes to have something which he has not had before, and he wants that to be good. In taking the advice of the catalogue he finds that a far greater number than he wants are mentioned in terms of commendation or high commendation; indeed, there are but few species offered for sale that do not admit of something being said in their praise. This is all very well, for it is no part of the seedsmen's duty to record anything but the bright side of the question, the other side is for the buyer to find out, or, at all events, it is for some one to do so for him. The latter is by no means an easy task, as there exists such a diversity of opinion that no one can curtail a list to any extent without shutting out what, perhaps, his neighbour would regard as deserving of being retained. Nevertheless, it must be admitted that most of our catalogues of flower seeds want a good weeding. One firm, a year or two ago (I believe it was the Messrs. Henderson), did put forth a list of such annuals as they thought might be discarded, and they did not receive the thanks which such a judicious step deserved; but as considerable additions are made every year, a good thinning out must at length be effected. It is not, however, my intention to go into this at present, but to call attention to a few of the most popular annuals which have come under my notice as deserving a place in most collections. At the same time I would invite others to point out those which may be equally deserving, and if some one would undertake the herculean task of telling us how many names in some of the larger seed catalogues ought to have the pen drawn through them he would confer much benefit on the community. Beginning, therefore, with a few annuals that are generally known, the notes on each will be very brief.

ASTERS.—These have been multiplied to a fault; but the

amateur might grow the French varieties, which are broad-petalled, and some are more or less recurved, and the German or Chinese Aster, which is quilled. The varieties of each are endless.

HEXUNIAS.—Though not strictly annuals, yet these flower well in the first season, and generally do much better than plants raised from cuttings. If seed from good purples could be depended on as coming true, they would be invaluable, as they continue flowering till frost.

ZINNIAS.—Good varieties of the single look well, and the double still better; but the latter are not so robust. As a plant there is a sturdiness about the Zinnia deserving attention.

LARKSPURS.—These are most beautiful when they sow themselves and flower where they come up. They transplant badly, and the slugs being very fond of them in a young state, they cannot be depended on when sown where they are to remain, especially if in a continuous row; otherwise their beauty entitles them to a place everywhere. The perennial kinds bear transplanting well enough.

STOCKS.—German and Ten-week exhibit great variety of colour, and a good proportion of double flowers may be generally obtained. Both are favourites.

HELICHRYSUM.—Good varieties of these are not only showy all the latter part of summer and autumn, but they furnish materials for winter bouquets. A row of about 250 feet in length, which we had last summer, was most useful. In good ground they become nearly as tall as Dahlias.

PILOX DRUMMONDI.—On soils suitable to this plant it rivals the Verbena, alike in the variety of colour and freedom of blooming. It requires, however, a rather moist situation, or a soil inclining to peat.

PORTULACAS.—A dry sunny bank is best for them, and there they are not excelled by anything I know for the variety and brilliancy of their colouring. The plant continues a long time in bloom, but it does not succeed well everywhere, and at times there seems to be a sort of capriciousness about it difficult to understand.

CALLIOPSIS.—Atkinsonii and one or two others are very good, but they are late-flowering, still their bloom may be hastened by sowing in autumn. Varieties of a more dwarf habit are wanted.

CLARKIA PITCHELLA and its many varieties have long been favourites, great improvement, however, has taken place of late years. One called integripetala is as good as any.

COLINSIA BICOLOR.—Nothing can be more beautiful than this flower, but, unfortunately, it remains only a very short time in bloom, so that its admission into beds composing a series is of questionable propriety, except for the few days it is out. A similar objection holds good with Nemophila, Schizanthus, and some other showy annuals.

PRINCE'S FEATHER.—This old annual is by no means so much grown as it ought to be, nothing can be more rich than it often is. It is of easy culture, and continues in flower till November.

LOVE-LIES-BLEEDING, like the last, is also a beautiful plant, differing only from it in the racemes being pendulous instead of upright.

SALVIA PATENS, of a fine blue, would be invaluable if its blossoms were more abundant. As it is, it is deserving of a place.

SALVIA ABROTANIFOLIA is a white, woolly-leaved plant, very showy. As an ornamental foliage plant it deserves to be more known.

ISOTOMA SPICIFERA.—A neat blue-flowering plant, deserving attention alike for its continuous flowering and its compact habit, which fit it for beds, and there, in years gone by, it was often met with.

DIANTHUS.—This extensive family presents several that are worthy of a place. *D. Heddewigii* was much admired a few years ago, but has fallen into disrepute as a bedder, though entitled to a place in the mixed border.

G. PINKA.—These plants, allied to *Gnaphala*, are also better adapted to mixed borders than beds. *G. Lindleyana* and its varieties are good.

S. CALYCEATA, &c., they require nothing said in its praise, unless it be to recommend it to the very few who do not happen to know it. It stands near the top of the list of annuals, especially for bedding, for which it is not approached in its way by anything else.

S. PLEUROPLEGANS.—The single-flowering variety of this is more showy than the double. For a bed of flowering plants 2 feet high this is deserving attention.

FRANCO MARIOLA.—Really good, dwarf, double yellow varieties have been common during the last year or two, and we may, consequently, expect these plants to be more sought after for bedding than formerly. They deserve a place everywhere.

AFRICAN MARIOLA.—These have not varied much like the last-named, but good flowers are at all times regarded as an acquisition.

GERMAN MARIOLA.—There is a prospect of a good white variety coming out, but as I have not seen it, I can give no opinion. These of the old class deserve more attention than they often receive.

LOBELIA.—The dwarf blue varieties of *Lobelia erinus* require nothing to be said in their favour, and the white and intermediate varieties are equally well known and approved of. I am not, however, acquainted with the taller annuals of this section, but the perennials are much grown and admired.

TACONIA SIGNATA.—This I consider next to *Saponaria* for general usefulness as a bedder, and superior to it in the duration of its flowering. The plant promises to be a rival to the yellow *Calceolaria*, which it resembles in size and habit, but it is even a more abundant bloomer than that very popular flower.

It makes an excellent edging to larger-growing plants, and for a line in a ribbon border is equally valuable. The individual flowers are small, but they are produced in such abundance as to cover the plant completely over, and this not for a week or two, but for three or four months, ending with severe frost. I can strongly recommend it for all purposes except bonnet-making.

TROPEOLUM.—I hardly know what to say of this family. A dwarf-growing variety, which becomes taller than the other, as it does not run, flowers most abundantly, and shows the flowers better above the foliage, but the trailers would be more easily kept in order if they did not grow too rank. If other plants be plentiful, I would not recommend *Tropeolum* for beds, although, as single plants, or to cover banks, they are invaluable.

HYPERICUM.—These are mostly regarded as perennials, requiring rather a moist soil.

NEMOPHILA INSIGNIS, and others, cannot be exceeded in beauty while they are in bloom, but in dry hot seasons the bloom is so soon over, that it is not advisable to depend too much on them.

SALIZYRUM, like the last-named, is very handsome, but it, too, is too transient beauty to be recommended for general purposes.

TRINERODIA STATA, and others, are climbers, and in hot seasons look better out of doors than in the houses. They ought, however, to have a sheltered situation.

TROCHILIDACTYLUM, though a perennial, will, nevertheless, often flower in the first season. It is pretty, but not very hardy, being apt to be killed in sharp winters.

COXYCUM.—I confess to never being so much in love with these plants as many have been, certainly they look well when full blown, but when the flowers close in they look badly. The plant is robust and sturdy.

ELYSIUM.—The varieties of *Perilla*, *Monum* are an improvement on that species, and look well. This is one of the best of annuals to stand the winter, with the exception, perhaps, of the *Veronica* *Stuck*, which is also good and well adapted for spring bedding.

CLINTONIA PULCHELLA.—I confess never being very successful with this annual, but I have seen it in good order; it seems to require a hot summer, and sunny position.

DEPHNYUM ROMOSUM, being a perennial, is hardly admissible here; but it may be treated as an annual, for mixed borders especially.

GLIANTHUS.—A pretty annual of neat growth, and deserving attention.

GALLIARDIA PICTA, and its varieties, are deserving a place where showy plants are grown, and when placed along with other suitable plants.

LEPTOSIPHON DENSIFLORUS, and others, are neat growers, and showing their bloom well above the foliage, appear to advantage.

LIASANTHUS DOUGLASSII is also, like the last, a compact, manageable plant of some merit, though not to compare with *Saponaria* or *Tagetes signata*.

L. PINES.—There are several species or varieties, but *L. polyphyllus* is as good as any of the tall ones, and deserves a place in the herbaceous border.

Besides the above there are many other annuals of merit, according to the wants of those who patronise them, but as this list has already extended farther than it was intended, it is not advisable to point out more of the flowering class, but there is another section remarkable for their appearance, to which allusion may be made.

PERILLA NANNIENSIS.—Too well known to require comment, its hardness is not the least of its merits.

BICINUS.—Castor-oil plants, remarkable for their handsome, large, palmate foliage. In a favourable season like last year, they will attain the height of 8 feet, and upwards, with but very little attention.

AMARANTHUS MELANCHOLICUS RULER has not become so popular as it was expected to be; it is certainly not so hardy as the *Perilla*, and dies off sooner in the autumn, but when at its best it exceeds the *Perilla* in appearance.

TRIFOLIUM.—This likes a dry, sunny bank, and its use in garnishing is, perhaps, not the least of its merits.

SOLANUMS.—A new era seems to dawn upon these, and we may expect to hear of several species remarkable for their fruit or their manner of growth. *S. marginatum* is about the best of the latter that I am acquainted with.

CANNAS.—These are not truly annuals, but may be raised from seed. Good varieties with a dark bronzy tint on the stems and foliage, and when of good growth and healthy, look well. They require plenty of moisture in summer, with heat as well.

INDIAN CORN.—Not by any means an uninteresting plant, as its appearance is truly tropical. It requires a warm season to perfect its growth.

GRASSES.—These are so numerous that I fear I must give up the task of enumerating them; but good specimens may be found in the genera *Agrostis*, *Briza*, *Pennisetum*, *Arundo*, *Eragrostis*, *Festuca*, *Hordeum*, *Panicum*, *Stipa*, and others, to say nothing of the Pampas Grass, the most graceful of them all. Grasses require special notice, but not being sufficiently well acquainted with them, I cannot enter into their merits fully. It is probable, however, that during the coming season some one will point out to us what it is advisable to grow, and what not, for this class, like the flowering annuals, will soon want weeding. At the same time accessions are acceptable when of merit. I have no doubt that other large-foliaged plants, and those of singular growth, such as the common Teazel, will have their admirers, and contribute their share to grace the back of the shrubbery, while the front is occupied by such plants as those noticed above. Perhaps some other contributor will give their names.—J. ROSSON.

POTATOES AGAIN.

I MAKE no hesitation, in travelling out of my own peculiar line, to say a few words more on the subject of this favourite esculent, and that notwithstanding the broad hint given me by the "man of Ross" that I should "stick to my last," as every cobbler ought to do. I do think it a very unkind cut to tell a man who has been partly brought up in the land of "praties" that he knows nothing at all about them, and then to come down on him with the physiology of the subject. On that point I do profess my ignorance, and beg to thank your correspondent for the enlightenment which he has kindly given me. Refuse, however, adopting his advice, I should like to

say a word or two. I want to know, if his physiology be correct, why it is that the Lapstones were as mealy as any one could desire if the ground was in fault and the power of control in one's hand. I cannot quite understand why they alone of all the kinds I tried should have fulfilled conditions which are only, according to "W., *Ross*," to be obtained by the application of special manures, such as sulphate of soda, nitrate of potash, &c.; and I am sorry to say that east is some consideration to "D." of Deal, but that on a small scale he would like to try these manures. How would "W." advise me to apply, say, the nitrate of potash? and as the Lapstones are mealy, would he recommend me to let well alone in their case? Many thanks, too, to "UPWARDS AND ONWARDS" for his notice of my short notes, and for his promise. I have written to Mr. Daintree for a sample of his new Kidney, and this will complete about a dozen sorts that I have for trial; and I can only say that if it beat the Lapstone it must be a really good one. Whoever recommended that variety I look upon as a good friend, and am at any rate glad that so experienced a grower as your correspondent agrees with me in my estimate of it.

I did not wish my growth of Potatoes to be dignified by the name of an experiment. I intended it far otherwise, and hoped that I had obtained in those I grew a sufficient number to keep me in a succession of good varieties. Had they all proved to be so, as I expected, I should not now be thinking of experiments or trying other sorts. I do not see the use of burdening oneself with a great number of varieties, and think that if we can have three or four good ones that is all we require. It is doubtless true, as "FORWARDS" suggests, that the last season was a peculiarly trying one to Potatoes, and therefore one must not condemn hastily before another trial; but Racehorse and Royal Ashleaf were found wanting before the change of season, which so completely dashed one's hopes of a good crop. As to Paterson's Seedlings, this is now the second season that I have observed them, and I have seen nothing about them to lead me to suppose that they will be different in any other circumstances. There are, as I have observed, numbers of Potato-eaters to whom flavour is a very secondary matter, but I am not one of them; and it is in the hope of clearing away some of the rubbish and obtaining a really good supply that I have ventured to obtrude my little experience.

I see "FORWARDS" unhesitatingly condemns Mona's Pride, while Mr. Myatt, who ought to know something about Potatoes, praises it highly; so does Mr. Wheeler, whose Milky White I have already spoken of as apparently a valuable sort, and certainly very excellent as I tasted it. I quite agree with your correspondent that it is ridiculous to give prizes for uncooked Potatoes. Why not make each exhibitor do as the vendors of Potatoes do in London—boil one or two, and leave them on the top of the dish? A Flake is a handsome Potato, but insipid to a degree. To give prizes as now, is only to be equalled by giving prizes (as I have known to be done during the last season), to Melons without tasting them.

In addition to those I named in my last communication I have some Kidneys from Mr. Webb's, Calcot Gardens, Reading, supplied to me through Messrs. Barr & Sugden, and Early Don, a round sort, highly spoken of by Mr. Turner, of Slough, besides one or two other round sorts; and I feel convinced that if some of your correspondents would kindly make notes of the sorts they grow, the character of the soil in which these are planted, and the manures used, it would be very useful to many who, like myself, are looking out for a good table supply for home consumption, and not for market purposes.—D., *Deal*.

CYCLAMENS.

We received some Cyclamen leaves and blooms, and some relative queries from a correspondent "S." which we forwarded to Mr. Atkins, and he has obliged us by replying as follows:—

"Thanks for the sight of the leaves and bloom from your correspondent 'S.' With the exception of repandum, (which is that of Sibthorp, true), and possibly the one marked on the back, and much more serrated than the other, they are all of the hederifolium type, though some of them belong to the Greek group. Of the latter I am not at present quite satisfied whether there are distinct species or only varieties; but from researches now making I trust this will before long be satisfactorily determined. I believe I have all of them, with, perhaps,

the exception of the serrated one alluded to: of this I cannot be certain without seeing the bloom. The leaf is much like that of the europæum I have collected in one district.

"One means of determining this, as well as distinguishing some of the others, would be to ascertain whether the leaves rise with, before, or after blooming, and, also, the presence or not of a coronet, or tooth-like protuberances, at the base of the petals—and are any fragrant?—some of the Greek ones are delightfully so.

"I hope before long to see the species satisfactorily reduced to some eight or ten at the utmost. Of upwards of fifty so-called species which I have received since I have been a collector, I am satisfied they will not exceed, if they even amount to that number.—JAMES ATKINS."

PEAR SCIONS EMITTING ROOTS — PARADISE STOCKS.

I AM much obliged by your having inserted my defence against the Paradise stock, and I was not surprised that you had no proofs to offer against its hardness. And I cannot but think that you prejudged the case, and thereby did me an unintentional injury. I think that the editorial "We think you are right" was uncalled for, it would have been best merely to have given space to Mr. Pearson's little spurt, and left the public to decide between him and me, as it is you have made yourselves parties in the matter at issue, and I think *partial parties*.

You have not been able to show any proofs against the hardness of the Paradise stock, and I am inclined to think that you have not much root to sustain you in the other case—*i. e.*, the protrusion of roots by the Pear from above its junction with the Quince.

I was engaged yesterday taking up a large number of Pears worked upon the Quince, and I examined many of them minutely, but found no appearance of the little phenomenon you and Mr. Pearson speak of as sure to take place. It struck me that it would be well for me to send you some of my trees, that had been planted an inch or two over the junction of Pear and Quince, that you might see upon what good reason I advise Pears worked upon Quince stocks to be planted an inch or two over the junction. You, I think, will do me the justice to see that in neither of the three trees sent are there any indications of Pear-roots being pushed out. The trees sent have been planted four years, and I think you will allow that they are not destitute of Quince-roots, if they have none from the Pear above. Any one who knows anything about Quince and Pear-roots cannot be deceived. I could have sent you trees that have been planted ten years, in the same way, but deemed them rather bulky.

I now challenge you and Mr. Pearson, and the other fellow, behind the scenes, who draws the strings for Mr. Pearson, to send me a Pear tree that has rooted from above the junction of scion and stock. If you, or any of you, will do this, I will pay £1 to the fund of the "Gardener's Benevolent Institution." But should you fail to do this, you will each of you pay £1 to the same fund. I claim, as a matter of fairness, to have this letter printed *verbatim*, as I consider it a little out of the way for parties to take up a trade catalogue and try to make themselves appear sapient by their hypercritical remarks on subjects they are *obviously* not acquainted with. We all know that trade lists are not, as a class, very correct; I know mine are not, so much so, as I could wish them to be, although I think that they will bear comparison with most of my contemporaries.—JOHN SCOTT.

[We insert the above without any omission or mitigation—though it would have been more merciful to Mr. Scott to have left out much, and to have softened more. Controversy does not require improper motives to be assigned to those who differ from us, and Mr. Scott, if he reflects for a moment, will feel that he was no more justified in charging us with partiality, than we should be in charging him with being prompted by self-interest. There *is* such a motive as the desire to establish truth, and we claim that as our motive in all which we insert in these columns—and certainly the present discussion is no exception—we have no interest to serve whichever opinion prevails.

Mr. Scott had acted more discreetly if he had allowed the Pommier de Paradis stock question to remain without further agitation, but since he intimates that we refrained from the

subject because we were not "able to show any proofs against its hardness," we will adduce Mr. Rivers as an evidence.

"The Pomme de Paradis seems identical with the Dwarf Apple of Armenia," referred to in the *Journal of the Horticultural Society*, Part 2, Vol. 3, page 115. It is exceedingly dwarf in its habits, and too tender for this climate, unless in very warm and dry soils. Out of 2000 imported in 1845, more than half died the first season, and two thirds of the remainder the following. They were planted in fine fertile loam, favourable to the growth of Apples, and on which the Doucin, planted the same season, grew with the greatest vigour. The same result attended an importation of 2000 in 1816."—(*Rivers's "Miniature Fruit Garden,"* p. 53.)

Passing on to the question whether the Pear scion emits roots when worked upon a Quince stock. We received from Mr. Scott three Pears so worked, and apparently four years old; the junction of the scion with the stock had been about an inch below the surface. But these afford no evidence that the scion will not emit roots. When the trees are eight or ten years old, and the diameter of the scion then more exceeds the diameter of the stock, then, if the junction has been buried from 3 to 6 inches below the soil's surface, the scion often will emit roots, and as we have seen the roots so emitted, no assertions to the contrary can prevail with us. We do not ask Mr. Scott to admit our testimony; but to show our readers that we are not without corroborative evidence, we add the following quotations:—

"In the planting, should the ground be moist and rich, I plant the trees at the same depth as they were previously planted and had grown in the quarter; but if, on the other hand, it is rather dry, I plant a little deeper, as I find they do better by being so planted, and roots often proceed from the Pear wood as well as from the Quince.—C. B. SAUNDERS, *Cosarean Nursery, Jersey.*"—(*Cottage Gardener*, xi., p. 286.)

The late Mr. Errington, one of the most experienced fruit-growers, remarking on that statement said—"Mr. Saunders heads rather low on the stock in order to plant low; and others call into action the fibres from the graft or bud, as well as the roots of the Quince; for, as he justly observes, such a course will cause fibres to protrude."—*Ibid.*, p. 417-8.)

These are unexceptionable witnesses, but we have inquired of Mr. Fish, Mr. Abbey, and Mr. Rivers, and the following are their replies:—

"PEAR TREES ON QUINCE STOCKS.—I have several times examined trees and found roots protruded at the swelled protuberance, where stock and scion meet, but not at all so uniformly as to make the rooting a general rule. I regret now that I did not take that interest in the subject, as to ascertain what kinds of Pear are most apt to root, when the grafted part is covered with earth to the depth of 2 or 3 inches. Apples will also root from the grafted part in similar circumstances.—R. FISH, *Putteridgebury.*"

"Apples on the Crab and Paradise stocks emit surface roots freely, particularly on light gravelly soils. We have some trees on both stocks that have rooted above the surface, and they root as freely above as below the junction of the scion and stock, as also do Plums. Pears on the same soil also emit surface roots abundantly, and nothing will prevent them doing so providing a bud or eye starts from the part covered with soil, and if a cut be made through the bark down to the alburnum roots come plentifully from the cut.

"Mr. Scott, however, obtained no surface roots from planting so deeply as to cover the junction of graft and stock, and we are left to conclude that the part of the stock buried will emit roots, but the part of the graft covered will not do so. This is not consonant with my experience.

"In 1859, I had under my care some Pear trees on the Quince in pots, and these had a swelling above the junction of the graft and stock, similar to that which is found in most fruit trees when the stock does not thicken correspondingly with the graft. They had been worked from 3 to 6 inches above the surface of the soil. From the unsightliness of the excrescence, and to obtain roots from the part of the stock not covered, it was decided to plant them out in a border so deeply as to cover the junction of the graft with the stock. This was done, and the union covered about 3 inches. The consequence was, that some did root from the lower part of the graft at its junction with the stock, and one peculiarity of these trees was, they did not emit roots from the part of the stock buried. The others rooted neither above on the Pear, nor below on the Quince on the parts newly covered with soil. They were examined annually, and some were found to have rooted both

from the Pear and the Quince parts of the stem buried, but it was not until the year 1862, that they all had rooted from the Pear part of the stem buried, with the exception of one, and that was Beurré d'Arenberg, and that had not rooted in 1863, on either the stock or graft part buried.—G. ABBEY, *Stanley Hall.*"

Since the foregoing was in type, we have been favoured by Mr. Rivers with a communication relative to the rooting of the Pear scion when grafted on the Quince stock, and he says that we are "perfectly correct." We shall publish his communication next week. It is replete with sound valuable information, not only on Quince but Paradise stocks.

Such an amount of testimony needs no comment, and we now leave the subject; but, for the sake of the Charity, hope Mr. Scott will pay over his wretched sovereignty to the Gardeners' Royal Benevolent Institution.—Eds. J. or H.]

THOMSON'S STYPTIC TO PREVENT BLEEDING OF THE VINE AND IN VINE GRAFTING.

In the year 1826 I was put in possession of three rather large vinerias. I was then very young. Since that date I have been more or less a cultivator and, I may say, devotee of the Vine, and during these years I have been a careful observer and experimenter. Few works were then out, and gardeners then, as a rule, would sooner mislead an interloper into their profession than afford him any reliable information, so that I was left to my own resources; but my motto was, and is—"Nil desperandum." I must apologise for this egotism; but I have merely stated it to show that it is not the fancy sketch of yesterday.

Bleeding of the Vine with me is an exception, not a rule, and may be easily avoided, with few exceptions—such as having to prune just before the sap rises, on account of late-hanging Grapes, or in consequence of unripe wood and some minor causes; but as there is now a certain antidote to bleeding, I will at once state my humble opinion as to how it is to be avoided. First, prune as early as possible; secondly, let pruning be done when the atmosphere of the house is perfectly dry, or light a fire to make it so, and then keep the atmosphere dry for a few days at least; but the longer the better. Avoid pruning in damp, muggy weather. I have found the best time for either early or late pruning is when the atmosphere outside is dry, and the readings of the barometer are high. In the first instance, if you examine the cuts, in a month or two you will find the wounds cauterised, if I may use the term, and you may in many instances cut the ends off with a sharp knife, and for the sixteenth or an eighth of an inch find the wood and pith perfectly dry, or healed; whereas in the case of a damp pruning time, and much damp in the house afterwards, you will find the cuts almost green, or, if not green, no particle of dead wood, or contraction of the sap vessels will be seen. Such is my experience in Vines in good health and vigour, and with well-ripened wood. With Vines, the wood of which is not well ripened, it is of double importance, as well as with long-hanging Grapes.

Now, I believe in the old saying—"There is no poison without its antidote;" and in the bleeding of the Vine the antidote or preventive lies in "Thomson's Styptic," advertised in your *Journal*, &c. A friend knowing I was fond of trying anything new, sent me a bottle as a present. I am happy to say that I did not require any for that purpose; but, considering the reputation of its inventor, I determined to give it a faithful trial. Having some Vines to graft, the sap of which was on the move, I reprimed the whole length of one rod, some twenty spurs, and applied the "Styptic" as it is called, choosing a dry sunny day, and in no case have I lost a drop of sap; this was about the 20th of January. I have since treated several Vines in the same manner, and with equally satisfactory results. Upon two or three spurs, it is true, I observed a kind of capsule at the end of the cut spur, I opened one, and by doing so a few drops of sap were lost; I waited till next day about noon, when the sap appears less active, made a fresh cut, and applied the "Styptic" again with the desired effect. The result to me is, that Vines pruned about the proper time and dressed with that composition, will be much benefited as far as a certainty of not bleeding with the rise of the sap is concerned, and that Vines may be pruned even a few days before the buds swell, if carefully dressed with that composition, with perfect satisfaction and success.

Grafting Vines is now occupying a good deal of attention.

My attention was directed to it more than thirty years ago, and on the whole my practice was attended with very marked success, and I hope before the end of the year to be able to introduce a simple and efficacious mode of grafting the Vine, by which a year or more may be saved.

Being desirous of working some new sorts upon established Vines and some young canes, I determined to try "Thomson's Styptic" *versus* my grafting-wax. I received some cuttings or grafts about the 20th of January, at which time the sap of some of the Vines had risen, and the buds were swelling. For graft the first I prepared the scion, the sap of which was rather up, and cut the spur in which it was to be inserted; then drop, drop, drop, away went the sap. I inserted the scion as speedily as possible, but before I could apply the wax the sap was dropping out of the end of the scion. I then put on the hot wax, but it soon sent the sap up in bubbles, and drop, drop, again, but "Nil desperandum," so I took the scion out, dried the end, dipped it into "Thomson's Styptic," and placed it in the sun to dry quickly, then took a piece of strong copper wire, and with a pair of pliers twisted it round the spur close to the main stem until it ceased bleeding. By this time the "Styptic" was dry on the end of the scion. I inserted the latter again, tied it, and applied the "Styptic." As soon as this was thoroughly dry I gave it another dressing, and in two or three hours took off the wire, and it and No. 2, four weeks after being grafted, have shot out nearly equal to the parent stem.

Graft No. 2 was equally forward; but I took the precautions of dipping the end and putting on the wire ligature, and in cutting the spur lost a drop or two of sap owing to its pressure. I inserted the scion, tied it, and applied the "Styptic" twice, with complete success, judging by the vigorous shoot.

No. 3 not being so forward, I did not take the precaution of dipping the end of the scion, but inserted it in the same way as the others. Next morning I found it bleeding from the end; but by a little perseverance with the "Styptic" the bleeding stopped, and the graft is now doing well. I also found some small bubbles at the junction of the grafts, burst one, and a little bleeding resulted; but by taking advantage of a dry atmosphere and the sun, I gave another coating, and all was right. I should have mentioned that only one coating was given at first.

The other grafts, numbering more than thirty, for use and experiment, were made when vegetation was not so forward, and they have all done well so far, except in a few cases where the scions were not appropriate in size, but I think every one will grow.—YORK.

TABLE AND VASE PLANTS.

I now fulfil my promise to enumerate other plants that Mr. Burns uses with good effect at Lougherew.

He uses at the dinner table different kinds of *Centradenia*, for instance *C. floribunda* and *C. grandiflora*; also *Isora javanica aurantia* and *I. coccinea*, which, when full of flower, look really beautiful, and with care last in bloom a very long time. *Vinca alba* and *V. rosea* look well; but the flowers soon drop. *Pentas carnea rosea* is a very useful plant for table; *Gardenia citriodora*, when nicely grown and full of flower, is most useful for either table or vase; *Euphorbia jacquiniiflora*, nicely trained on small wires, has a very pretty appearance. Of fine-foliaged plants *Adelaster albivenis*, *Pandanus javanicus variegatus*, and the *Marantas* mentioned at page 143, form the principal; but the *Pandanus* is the king.

Fine-foliaged plants for the breakfast table are *Pothos argyrea*, *Sonerila margaritacea*, the *Eranthemum*, and others mentioned before; also *Selaginella Martensii*, *S. stolonifera*, and *S. dichrons*; but *S. plumosa* is, for table purposes, the best used there.

For vase plants in the rooms are used different varieties of *Begonia*, small plants of *Cyanophyllum magnificum*, *Rivina humilis* when full of berries, and *Croton discolor*, *C. longifolia*, *C. picta*, *C. variegata* (I may just mention, in speaking of *Crotons*, that Mr. Burns has a sport, which, if it remain true, and it is likely to do so, will prove a most valuable addition to the *Croton* family), *Cyrtanthera magnifica*, *Eschynanthus splendens*, and different varieties of *Francisceas*, *Gardenias*, *Abceasias*, and *Caladiums*, besides all those mentioned for table decoration.

Before concluding I may state that Mr. Naper no doubt possesses the best, or one of the best collections of stove plants

to be found in the provinces in Ireland. His *Caladiums* are grown to an immense size, more like *Rhubarb* than anything else to which I can compare them, although by the skilful management of Mr. Burns they retain that great beauty of foliage for which they are so justly noted. Mr. Naper has a plant of *Sphaerogyna latifolia* upwards of 6 feet high, and furnished to the pot with its immense leaves. In bedding and ribbon work the place is not surpassed in Ireland, as nearly forty thousand plants are bedded-out every season. I have often wondered that "D." of Deal, has never visited that pretty part of Ireland. I have no doubt that if he called Mr. Burns would make him very welcome, and perhaps give him one or two of his secrets, that I can testify are worth knowing.—R. M.

RAPHANUS CAUDATUS, OR LONG-TAILED RADISH.

Will you allow me to call the attention of your numerous readers to this new and valuable vegetable, the seeds of which, I see, are now being sent out by Mr. Ball, of Chelsea?

It is a native of Java, and is much used in some parts of India in salads, and being perfectly hardy here, it is likely, I think, to prove very useful. It appears to be one of the Radish tribe, but unlike that esculent the seed pods, not the root, are eaten; these are very curious, attaining an immense size in a wonderfully short space of time, sometimes growing 5 or 6 inches in twenty-four hours. The pods are usually from 2 to 3 feet long when full grown, some being straight, others curled into the most fantastic shapes; they are of a most agreeable flavour, and when half grown can be eaten in the same way as a Radish, which root they greatly resemble in taste, though their flavour is more delicate. It is, however, when the long pods are boiled that they are most delicious, tasting then much like Asparagus, with a slight green-Pea flavour. They should be served on toast, and will form a most agreeable addition and novelty for the table.

The plant is easily cultivated. The seed should be sown in slight heat about the middle of May, and the young plants, when fairly up, planted out in the open air in good rich soil. No further attention is needed except to keep the soil well watered in dry weather, and to keep the ground clear of weeds. In two months from the time of sowing the plants will begin to produce most freely their long pods, which must be gathered young—i. e., half grown, if required for eating raw or for salad. For boiling and picking they should be suffered to attain their natural size.—J. H.

[It is called *Mougr* in Java, and the specific name "tailed," refers to an appendage of the pods.—Eds.]

RAINFALL AT THWAITE, SUFFOLK, IN 1864 AND 1865.

I AM indebted to Mr. Orlando Whittlecraft, meteorologist, Thwaite, in this county, for the accurate statement of the rainfall in 1864 and 1865, showing the remarkable disparity of the two years. The mean annual rainfall in Suffolk is 22½ inches.

	1864.	1865.
January.....	0.76	1.98
February.....	1.04	1.72
March.....	2.62	2.07
April.....	0.61	0.53
May.....	2.25	1.85
June.....	2.49	2.02
July.....	0.87	5.40
August.....	1.66	5.67
September.....	2.36	0.00
October.....	1.50	8.30
November.....	2.80	2.12
December.....	0.75	1.15
Total.....	19.71	32.81

Mr. O. Whittlecraft has watched very closely from boyhood the various phenomena of the atmosphere, and is the author of the "Climate of England," "Rural Gleanings," "The Weather Almanack," &c. The latter has gained for him a world-wide reputation, the correctness of his predictions surprises even the most incredulous. Out of fifty predictions in one year, only four errors occurred, and in 1859 scarcely one decided failure. If a man, by close observation, can arrive at such just conclusions, his predictions are worthy of the attention of all those who are in any way interested in the weather. Both the farmer

and the gardener, and even the pedestrian, may consult the almanack with great advantage ere they commence operations. — JOHN PENNISS, *Thornham Gardens, Suffolk.*

LANGTON.

THE SEAT OF JOHN JAMES FARQUHARSON, ESQ.

AMONG the pleasant reminiscences of my horticultural visit to Dorsetshire last summer, the pleasure I experienced in inspecting the gardens at Langton, is still fresh, notwithstanding that some months have since elapsed. Gratifying as it is to see horticulture practised with skill, and carried on in a spirit worthy of the art, and I may also add the word science, for it must be acknowledged to be both, it becomes almost a duty to record instances that come under notice, where the teachings of science are applied in aid of practical experience. It was through the interest of my kind friend, Mr. Radclyffe, that I was enabled to visit, and to be introduced to Mr. Knox, the gardener at Langton, and to him I have to tender not only acknowledgments for the opportunity of seeing the place, but also a sincere apology for the delay in forwarding my notes to the Editors, knowing that it was expected that I should do so. I was fully aware for some time that the space in "our Journal" would be required for important matter, and it happened, too, that many circumstances at the time combined to prevent putting my notes into a form suitable for publication.

The drive from Rushton to Langton, though not exceeding three miles, is both beautiful and interesting; the undulation of the country rendering it beautiful by the variety of scenery presented at every successive turn of the road, interesting especially in summer, by the fine appearance of the crops on the arable land, and the luxuriance of the herbage in the meadows and pasture fields, testifying to the high character of the agriculture for which the county of Dorset is famous. This is particularly the case along the valley of the Stour, the slopes on both sides of the stream vividly calling to mind the lines of the enthusiastic poet in his eulogy of England—

"Warm with culture, the thick clustering fields
Proliferous team."

This is no ideal picture, it is an actual result obtained by the intelligence and perseverance of the occupiers of the land, several of whom I have had the pleasure of meeting in company, and whom I have found to be thorough-going, kind-hearted Englishmen. Their good tillage is, doubtless, favoured by considerate and equitable landowners, and supported by a sturdy and hard-working peasantry. These remarks are intentionally introduced from the fact that the condition of the Dorsetshire labourers has recently been brought prominently before the public in an unfavourable light. However true may be the particular instance that has been the cause of so much comment in the London and other newspapers, it is evidently illogical to apply the case of an individual to a whole class. Hence honourable and worthy gentlemen, their employers, have been brought into disrepute (indirectly, it is true) for causes from which they are as free from censure as those who have been so ready to invoke it. I have more than once seen many of the Dorsetshire labourers at their daily work, and assembled together on the Sabbath in the House of God, clean and neat in their attire and person, attentive to the duties that led them there in company with their employers, and others above them, independent but respectful and cheerful in demeanour. I have also visited some of them in their cottages, clean and comfortable homes, inspected their productive and well-managed garden plots, admired their ingenuity and thrift in the care of their bees and pigs, and have witnessed the honest pride with which they have related with many words how they won a prize for honey, another for Potatoes, and so forth at the neighbouring local shows.

Langton is situated one mile from the town of Blandford. It is the seat of John James Farquharson, Esq., a gentleman much beloved and respected by all classes, and an old and valued friend of Mr. Radclyffe's family. The residence is palatial, and of costly construction. It was designed by the distinguished architect, Cotterell, and was the last built under his direction before his death. It took five years in construction, and cost, it is said, £100,000. The internal arrangements of the mansion are most complete, and the stables, with the other necessary offices of a first-class establishment, are on a corresponding scale of excellence, the whole construction being that of a master mind, and the materials the best that wealth and art could put together. Mr. Farquharson, or as he is generally

denominated, "the good old squire," is an octogenarian, and is, it is to be hoped, in good sound health. Long may he be preserved to the county of Dorset, and neighbourhood of Blandford. Besides for his hospitality, the county owes him a debt of gratitude for hunting the whole county at his own cost, with his celebrated fox hounds. One can tell pretty well the character of a gentleman by the conduct of his servants. From them I received the most polite attention, especially from Mr. Knox, formerly with the Duke of Northumberland, at Alwick Castle, and now Mr. Farquharson's head gardener, and truly it is no idle compliment to speak highly of an intelligent, industrious, and hard-working man, who seems to have nothing so much at heart as his employer's interest. Mr. Knox fully shares in the distinction gained by his countrymen, our northern brethren, in their successful fruit culture, the vineries and Pine-houses being a marked feature in the horticulture of Langton. A circumstance of which I was afterwards informed is deserving of note. So careful and anxious is Mr. Knox, that the plants under his care, particularly the fine specimens to be presently noticed, are strictly attended to, that he does all the potting and re-potting with his own hands, notwithstanding that he has sufficient help at his command.

Under such efficient guidance, I now note what the various houses contained. The first is occupied chiefly by tropical and sub-tropical Ferns; specimen plants of the following were conspicuous, both for size and healthy appearance—*Woodwardia radicans*, *Adiantum formosum*, *Asplenium nidus*, *Adiantum trapeziforme*, *Blechnum australe*, and some of the *Lycopods*.

The second house, a vinery, was occupied by Black Hamburghs, and Vines in pots for dessert and dinner-table decoration, and the third by fine-foliaged plants. Among them the following well-known species were remarkable—*Pracema ferrea*, *D. terminalis*, *Caladium argyrifolium*, *C. Chantini*, *C. Belleyerii*, *C. bicolor splendens*, *C. pictum*, *Dicliandra picta*, *Croton variegata*, *Tradescantia discolor lineata*, with some of the most distinct *Begonias*. The fourth house was devoted to Melons, the kinds in cultivation were Meredith's Cashmere, Scarlet Gem, and a seedling of Mr. Knox's (green). The sixth was a Pine stove for succession; the seventh a forcing stove for various subjects; the eighth was for Pines then being out. The fruit in this stove was one of the most interesting features of the place, on account of the size, weight, and flavour obtained. Many of the Pines when measured were found to be 12 and 13 inches in height, thus attesting the perfection of the cultivation.

One may devote particular attention to the cultivation of one kind of flower or fruit, or to a class of plants, or to the introduction of ornamental species, that would give a novel and improved appearance to the garden (and, indeed, striking and even great results have been obtained by the concentration of the energies of distinguished men upon the subject to which they have devoted their special care—instances of this are evident in the case of the Rose, *Gladiolus*, Strawberry, Orchids, Ferns, and Conifers); but if I were asked, "In what department of horticultural art have the most useful, and the greatest general services been rendered?" I should without hesitation reply, "In the kitchen and fruit garden." When, therefore, these departments show the highest development, so far as the present state of gardening admits, a corresponding feeling of satisfaction predominates. Such was my impression while looking over the kitchen garden at Langton, at a time when the greater portion of the principal crops were approaching maturity. The fine climate of Dorsetshire is assuredly favourable to these departments, and last season particularly so; and not at Langton only, but in other places which I had the pleasure of seeing, the remark holds equally true. Among them I may mention Bryanstone, the seat of Lord Portman, where the superb condition of the wall fruit, and the productivity of the crops were, to me, matters of astonishment. To single one case out of many: several roots of different kinds of Potatoes were dug up at random in my presence in different parts of the garden, and the yield was in every instance not less than twenty-five good-sized tubers, in many thirty; and as many as forty, and even forty-five, were counted on one root. Had his lordship's courteous permission to take notes of what I saw during my inspection been received in time, I should have felt bound to have forwarded you those notes. I can now only offer my best thanks to Mr. Leach, the head gardener, for his kindness, and the great trouble he took in showing me over the splendid gardens and grounds at Bryanstone.

The Strawberry crop at Langton last summer was light, owing, no doubt, to causes that have already been sufficiently

discussed in former Numbers of the Journal. The kinds found to be most generally serviceable, are—Rivers' Eliza, Eugénie, Prince of Wales, and two or three other esteemed and well-known varieties. For forcing, Alice Maud, and Keens' Seedling, are chiefly used.

The flower garden is on the south-east side of the mansion. The arrangement is simple but elegant, consisting of beds for summer decoration, with borders for the best perennial plants, with clumps of shrubs planted here and there. As description without a plan is not intelligible or even possible, it will be sufficient to state the kinds of bedding plants used. The display was brilliant without being gaudy, and the harmony of the colours all that could be desired. The plants employed were: Geraniums—Trentham Rose, Christine, Tom Thumb, Beauty of Brinton, a variety with large trusses, very good, Zonate kinds; Cerise Unique, Compacta, Variegated Alma, Bijou, Flower of the Day, and Mrs. Mangies. Verbenas—Firefly, Ariosto, Purple King, Lord Raglan, Mrs. Holford, Desdemona, Perfume, Madeline, White Perfection, and a seedling pink of Mr. Knox's raising, a very useful and effective colour, distinct and free blooming. Mr. Knox does not think this seedling of sufficient merit to send out; but I thought at the time that there was room for a different opinion of it. It is invidious to set up one flower to distinction against another, as the bedding Geranium has sometimes been against the Verbena, much to the disfavour of the latter, and I share in the regret which some florists have expressed, that Verbenas generally, excepting Purple King, have been greatly discarded without sufficient reason, and often replaced by other subjects by no means surpassing them. Though one season may prove unfavourable to the Verbena, and favourable to the Geranium, the conditions as regards these two flowers may be just the reverse in another year. Last season showed that where good kinds of Verbenas were bedded out, in nearly every instance a satisfactory continuous bloom resulted. I hope that we shall see more of them than we have of late; the beds at Langton were excellent. Besides Geraniums and Verbenas, the following plants were used, either for edging or otherwise—*Cerastium tomentosum*, *Koniga maritima*, *Perilla nankinensis*, *Centaurea argentea*, *Cineraria maritima*, *Mentha rotundifolia variegata*, *Tropaeolum Lobbianum*, and *Calceolaria Aurea floribunda*.

The parks in which the mansions of the principal landowners of the county of Dorset are situated, are surpassed by few in the fine appearance of the deciduous trees with which they are adorned. This is especially the case at Langton, Critchill, and Bryanstone. At the last-mentioned the appearance in summer is very manifestly improved by the intermixture of exotic species, that have now attained considerable size. Among them I noticed *Acer eriocarpon*, *A. platanoides*, and some of the American *Crataegus*. I mention this to remind your readers that the planting of exotic deciduous trees, which would so materially add to the beauty of our park and woodland scenery, is still deplorably and unaccountably neglected, excepting in the public parks, and a few other places. Conifers are not extensively planted in Dorsetshire—*i.e.*, in the places I visited, it being found that the soil is not very favourable to their growth.

As it has been announced that the worthy rector of Rushton will shortly retire from his clerical duties, permit me in conclusion to join cordially in the wish so aptly expressed by your correspondent, "*D., Deal*," that he may long enjoy his *otium cum dignitate*, a wish which I am sure will be heartily concurred in by all who have the happiness of knowing him.—ADOLPHUS H. KENT.

BURYING THE STEMS OF ROSE TREES.

I HAVE always thought that to bury the stem of any tree more than 1 or 2 inches is contrary to nature, but mention being made by "*T. T.*," at page 142, of some trees, the stems of which had been buried 4 feet, I was reminded of some Rose trees which the head-keeper planted at his cottage here. They were planted 4 feet deep, the only object in doing so being to have them dwarf. Well, such wood and such blooms I have never seen before nor since, scarcely a sucker makes its appearance, and the watering-pot is never required.

I have made it a practice for several years to put clay on the branches of Peach, Nectarine, and Apricot trees, when the sun has in any way ruffled or cracked the bark, and I always found at the end of the season that some nice new bark had been made. Some years ago we cleared the stems of several Oak and other trees which had been buried several feet, but I never saw that the branches were injured at all; the only case that I

remember was a Lime tree which had been earthed up several feet, and the tree will never recover.

With respect to Grape Vines, I am in favour of keeping the stems above ground, the bark being more tender than that of most other trees, and, consequently, more likely to decay.

Perhaps "*T. T.*" will kindly give us the names of the trees which have done so well on the "landing-up system."—JOHN PERKINS, *Thornham Gardens, Suffolk*.

ROYAL HORTICULTURAL SOCIETY.

WE are authorised to state that the Council of the Royal Horticultural Society, having received an application from Mr. William Earley, Digswell, that the Journal of the Society should be supplied to gardeners at a cheaper rate than to the public, have determined that any *bona fide* gardener sending to the Assistant Secretary, Royal Horticultural Society, South Kensington, the sum of 4s. 4d. in postage stamps, being one-half the charge to the public, will be supplied with the Journal quarterly for twelve months.

THROUGH the continuance of the severe frost that commenced in the middle of last week, the Meeting on Saturday last was not well supplied with exhibition subjects. Messrs. Cutbush & Son were almost the only exhibitors, and they filled one of the large tables entirely themselves with a large collection of forced flowers and a very fine exhibition of forced bulbs, to both of which first prizes were awarded. Messrs. Cutbush also exhibited some well-bloomed plants of forced Lily of the Valley, which received an extra prize. Mr. Young, gardener to Mrs. Barclay, of Highgate, sent a large and handsome specimen of *Oncidium sphacelatum majus*, full of bloom, and which elicited much praise in favour of Mr. Young's successful cultivation. It was awarded an extra first prize. Messrs. Lucking, Brothers, sent a fine collection of forced flowers, which received a first-class certificate.

VERBENA CUTTINGS FAILING.

CAN there really be a disease amongst Verbenas? I thought the only reason they have done so badly this season, is, as stated in the Journal of February 6th, being covered with thrips.

A friend of mine, and generally a very successful grower of the Verbena, has the following plan.

Early in July he takes a few cuttings of each kind and dibbles them in the alleys between his Asparagus-beds. After well watering they require no further attention, except a sprinkling with the syringe to keep them from drooping, as the Asparagus stems give a nice shade.

When grown a couple of inches high the tops are pinched off. By the end of August they are taken up, three or four plants put into a 48-pot, kept out of doors free from worms, and the branches stopped as required. By the usual time to take into the greenhouse they are strong and bushy. This season he finds, is no exception. I should scarcely like to say how many dozens of cuttings could be taken from each pot at the present time.—W. C.

WINTER TREATMENT OF POT VINES.

THE fruiting of Vines in pots often leads many young beginners into difficulties, and in some cases they lose their situations through buying from the nurseries, for fruiting in pots, Vines which have been growing in bottom heat all the summer, in many cases up to the end of August or September, when they are ready for sale. They will then have filled a 10-inch pot with good, well-ripened roots and masses of fibres; and the canes will be 6 feet long, short-jointed, in fact everything that can be desired. A gardener obtaining the permission of his employer to buy some pot Vines for starting early, say in January, would most probably order them in October. The employer would then inquire if the Vines had come, and the gardener would answer in the affirmative, and say they were in excellent condition and sure to produce a good crop of Grapes. Such a result would not be unlikely if they were treated properly from October to January. Now, where are the pot Vines put when the gardener receives them? Any place will do for them till they are wanted, he often says—out of doors exposed to all weather, cold rains, frost, and hot sun. It is very certain that the canes will look all right throughout; but how is it with the good roots and masses of fibres, without which we cannot have fruit? They are too often dead by the time they are wanted, in consequence of exposure to too much wet and cold, or from drying in a shed.

The consequence is, the Vines will break very well, but very seldom show fruit, and the gardener is very much disappointed, the master becomes discouraged, and, perhaps, the evil does not end there.

I will now endeavour to show the beginner and those who have not had much experience in fruiting pot Vines, how to save the small fibrous roots and so make sure of plenty of fruit. If you buy your Vines, do that as soon after September as possible, take them to the potting-bench, and with a hammer gently break out the bottom of the pot, taking great care not to injure the roots. If the Vine is in a 10-inch pot, place it in an 18-inch pot; if received in one of greater or less size, use a larger or smaller pot accordingly. For soil employ good maiden loam enriched with manure, and let it be far enough below the rim of the pot to allow of good summer surfacings. I find a good rough loam well mixed with well dried sheep manure, such as one would find at the bottom of the manure-tank, a first-rate mulching. If the Vines want pruning, let this be done at once, as they will be sure to bleed if cut a month before starting. After potting place them in the greenhouse, or in any structure from which the frost and rain are just excluded, giving them a little water two or three times, just enough to keep them from becoming too dry, and if proper care be taken of them after starting, few gardeners will have cause to complain of their pot Vines not fruiting.—H. COMBLEY, Gardener, Hendre.

JOINTS OF CUCUMBER AND MELON-FRAMES.

WHEN out of use the difficulty of storing these frames renders their needless exposure to the weather almost a necessity; and

when required for use, they are so cumbersome, when large, as to require an amount of labour that is rendered needless if the joints are so constructed as to admit of their being readily taken to pieces. We have seen the ends of the sides so cut as to admit of this, but, then, what with the swelling of the wood when wetted, and the hammering consequently required, joints thus constructed were soon broken, and the plan condemned. In America they acquire the convenience, and avoid the evil, by having the joints made of iron, as represented in the annexed drawings, which we copy from the *Canada Farmer*.

UPRIGHT TUBULAR BOILERS.

In accordance with Mr. Cooper's request, I have much pleasure in giving my opinion and experience of Clarke's water-jacket boilers. I have had them at work for nearly three years, and they seem to act now as well as they did at first. I consider that they are the best boiler constructed, that they will not be readily surpassed by any subsequent invention, and that they possess all the qualities which your correspondents consider desirable.

Previous to having Clarke's boiler, I used the saddle, but I find as much difference between the two as there is between a locomotive and the old stage coach. Mine are two £25 double tubular boilers, they are 4 feet 6 inches high, and 3 feet in diameter. If any of your correspondents is doubtful about the working and advantages of these boilers, he had better come and look at the two I have, and which heat eight houses. The lengths of these houses are, one of 55 yards, one of 30 yards, two of 26 yards, two of 17 yards, and two of 11 yards. Two boilers of the same size may also be seen at the proprietor's residence, Vinery House, Allerton, near Liverpool, and they have more to do than mine. I think he told me that they had to heat about 6000 feet of piping. The visitor would there see, I believe, four of the finest vineries in England.—AMBROS WHITEHEAD, Park House, Presto t.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE ground during the past month has been generally drenched with rain, so that gardening operations could not be prosecuted with vigour, but the frosts and biting winds that we are now enduring, though unfavourable to vegetation, have afforded a very seasonable opportunity for forking over ridges, wheeling manure, and trenching up pieces of ground as they became vacant. The soil will be in fine condition, and committing seed to the earth must be vigorously followed up on all suitable occasions. Continue the general sowing of main crops according to the state of the soil and the locality. *Brussels Sprouts*, make a small sowing of this, as also *Borecole* and *Green Savoys*. To secure heavy crops of *Borecole*, a deep rich soil is essential, and the ground should be trenched 2 feet deep and liberally supplied with manure. *Carrots*, sow the main crop; a light deep sandy loam is most suitable, and, as manure induces forked and ill-shaped roots, ground which has been manured freely in the previous season should be selected. The soil should be trenched deeply. *Cauliflowers*, attend to the pricking-out of these, also of *Lettuces* and *Cabbages*. *Leeks*, sow full crops of the London Flag. The ground for this crop should be heavily dressed with well-rotted manure, and trenched 2 feet deep. Some growers dig out narrow trenches, and fill in with manure, as is done for *Celery*, but, except on very poor soil, this is unnecessary. *Onions*, continue the main sowings. A rather strong, deep, and rich leamy soil is most suitable for this crop. Where very large bulbs are desired, soil of this nature is required, and it is observed that Onions grown on a strong soil are less liable to be attacked by the maggot than in light sandy soils. *Peas* and *Beans*, in sowing these, if there is any fear of their being attacked by the wire-worm, it is a good plan, after they are sown in the drills, and previously to covering them in, to water them with spirits of tar, diluted with water in the proportion of one pint to six gallons of water, and mice do not take to them so readily when they are thus treated. Advancing crops of *Peas* and *Beans* should have more earth drawn to them, and some branches of *Spruce Fir* or other protecting material stuck in on the windward side of the *Peas*. *Parsnips*, sow the main crop; they succeed best in deep free soil, and, as the application of manure tends to the production of forked or badly-formed roots, the ground to be trenched 2 feet deep and manure applied at the bottom. *Potatoes*, attend to putting in this crop. *Salsafy*, sow full crops of this, as also of *Scorzoner*. *Herbs*, dress *Mint* and *Tarragon* beds with light decomposed manure. Look over *Herb*-beds, prick them up, and add fresh soil where necessary; now is a good time to divide the roots, and make fresh plantations. *Sea-kale*, make fresh plantations of this and *Rhubarb*. They delight in a deep rich soil; it should be trenched 2 or 3 feet deep where it can be done, working in a good quantity of rich manure during the operation. These multifarious directions betoken a busy season; they must be systematically followed up with attention to neatness; whatever is commenced should be completed, and left as neat as possible.

FRUIT GARDEN.

We must look out for the opening blossoms, and be ready on the first emergency to afford protection. Woollen net, stout straw ropes stretched upon poles, or light frames covered with oiled calico, are among the available materials for the purpose. If not already done, finish the pruning and nailing of fruit trees. Should any of them be subject to the caterpillar, dust them well with newly-slaked lime or soot immediately after a shower of rain, or dash water amongst the branches; this should be done immediately, before the buds are too far advanced. For the destruction of the Gooseberry caterpillar, now is a good time to rake away the earth from the stems of Gooseberry and Currant trees, and to dress them with soot and wood-ashes, returning the earth as soon as it is performed; prevention is better than cure, and this will save much hand-picking by-and-by.

FLOWER GARDEN.

Prepare a scheme for filling the beds in the flower garden, and estimate the number of plants required in order to propagate a sufficient stock without delay. Dress, when bulbs are coming through, with care, and plant out autumn-sown annuals. Those who plant old roots of *Pahlias*, which, by-the-by, are superior to young cuttings for general display if properly staked out, may put them in short, soiling them over 4 inches deep for fear of frost. Plant *Lily of the Valley* when requisite.

Plant out Pansies, Carnations, &c. Sow Wind Anemones for autumn flowering, and attend carefully to the sowing of hardy annuals, placing inverted pots over them where shy or liable to be devoured. Do not forget Mignonette and Sweet Peas. Have soil and pots in readiness for potting Carnations, for which purpose mix up three parts turfy loam, two parts well-rotted cowdung, and one part rough sand and charcoal together, and remove this compost into the potting-shed.

GREENHOUSE AND CONSERVATORY.

The usual campaign of potting must forthwith commence, and continue, where complete cultivation is aimed at, with scarcely any intermission until next October. Formerly it was the custom to top-dress all greenhouse plants in February; but now, however, there is much less of this top-dressing, and plants are shifted by good cultivators according to their habits and the purposes for which they are intended. The erroneous practices consist in overpotting, or potting in too rich a compost, plants which naturally run too much to leaf. It is obvious that such plants as the Veronica Andersoni will not bear the application of such stimulating composts as the *Thunbergia alata*, neither should they be so suddenly indulged with liberal pot-room. For plants of gross habit, plain, simple, loamy soils will in general be found quite rich enough without the addition of stimulating manures. The Camellias intended for flowering late in the autumn should now be forced into wood under a temperature of from 60° to 65°, shade is necessary while making their young wood. Those exhausted with flowering should be cut back and removed to a cool greenhouse for three weeks, giving them a little liquid manure. The same practice will do for the Indian Azaleas. See to regularly shifting the *Cinerarias*, *Palargoniums*, *Calceolarias*, *Fuchsias*, &c. Heaths may now be shifted. Use abundance of drainage and sandy heath soil full of fibres; thrust it in lumps round the ball, now and then forcing down pieces of stone or lumps of charcoal; and finally coat over the surface with some of the finer portions of the soil, which should contain a liberal amount of sand. The ball must be thoroughly moist before shifting, for if completely dry no after-watering can bring it right. Pot Cape and other bulbs as soon as the foliage is becoming strong. Use chiefly loam, leaf soil, and silver sand.

PITS AND FRAMES.

Maintain a kindly heat in the cutting-frame, top those cuttings that have taken root and are beginning to grow. Divide and pot singly into three-inch pots the old stools of herbaceous *Lobelias*. Fill a box with roots of *Verhena venosa*, and place them in heat. Mixed in a bed with Golden Chain Geranium these were very effective at Shrubland Park. Continue to put in cuttings as previously recommended. Remove the autumn-struck cuttings which were potted off last month, into a cold frame or pit. One of these cold pits should be filled up with ashes for the reception of the thinnings of the greenhouse. Many of the hardwooded tribes may be moved here and matted at night. This will make way for the increasing size and number of the *Fuchsias*, *Verbenas*, *Cinerarias*, *Calceolarias*, &c.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

MERELY attended to vegetables, &c., under protection and glass. Placed some hay and litter over Broccoli that was forward, protected Cauliflowers, wheeled when the ground was hard, and dug and trenched when soft and dry enough.

Snow.—There being a fall of from 3 to 4 inches of snow on Monday night and Tuesday morning, attended with a temperature not below freezing point, a number of men were sent to roll the snow into huge lumps, and then wheel it at once into the ice-well. Where the snow can be collected near the ice-well this is a better plan than using carts lumbering about. Almost every schoolboy knows how to roll a huge snowball. A good lump is collected and patted with the hands, and then turned over and over, taking up the snow as it goes. This was done so regularly that we quite cleared a piece of the park, the want of frost before the snow came causing the snow to come up clean from the grass. In loading, the barrow was placed on its side, the huge lump rolled into it, and then the barrow raised to the level, and wheeled to its destination. The road to the ice-well became very sloppy towards the afternoon, still with more men any quantity of snow might thus have been collected. When well thumped together by heavy beaters, it

is almost as good for keeping as ice. Our general practice is to do nothing with ice or snow before the men have a warm breakfast; but on this occasion, as other work had to be done in the morning, the preparatory work for the snow was done before breakfast, and we were alarmed by a very healthy man taking a fainting fit as soon as his hands touched the snow. He was all right next day, but we mention it as a warning, that no such work at any time should be engaged in before the men have breakfasted.

In general, the younger the lads are, the better they will roll the snow. Anything like gloves is generally unnecessary. After the first handling there will be little of the sensation of cold in the hands, quite the reverse. We have seen shovelling resorted to instead of rolling, but that is a tedious process, and does not compress the snow as rolling does. When carts have to be used, the huge lumps can be divided and pitched in with shovels. Such snow thus stored we have found more prized than ice by some butlers and housekeepers, more especially if a good thickness of ice was placed over the snow, thus compressing it still more effectually. It packs better round vessels than ice would do, unless crushed by the process advocated by Mr. Perkins. We hope to have the pleasure of placing ice above the snow to-morrow (Friday) morning. On Wednesday morning there was a sharp frost, but no ice, except where sheltered from the wind, the wind keeping the surface of the water in motion. On this (Thursday) morning, the coldest of the season, ice is formed, and there is every appearance that it will be thick enough to bear the ice hooks to-morrow. We shall have to be satisfied with breaking it sufficiently, so that there shall be enough of small ice to pack among the larger pieces.

FRUIT GARDEN.

Went on with pruning out of doors in favourable weather. Syringed the trees in the orchard-house with the sulphur-and-lime water, wetting every twig the pots exposed, and allowing it to run down the wall. This is done merely as a matter of precaution. We scarcely had an insect of any kind in these houses last season. If the frost is likely to be sharp to-night, will shut up these houses, as we did last night, having previously left all the air on that we could to be safe from wind, so as to keep the buds back. As these buds are swelling now we should not like them to have too much frost. A little will not only help to retard them, but will help to destroy any eggs of insects that must have been coming forward in the mild weather. With the buds in the present state, only a very few beginning to show colour, we should consider the trees quite safe in the still somewhat-dry atmosphere of the house if the temperature out of doors did not fall much below 20° from the freezing-point. We would hardly consider the buds of Apricots and Peaches out of doors safe if the thermometer indicated merely from 8° to 12° above zero, if no protection were given to them. On Thursday morning, having nothing better at hand, shook out some long litter from the stables, and stuck handfuls of it all over the Apricot trees, and some Laurel branches over the Peach and Fig trees out of doors. This litter can very soon be removed, and if the frost continue severe it will tend to keep all safe. We recollect of one March when the frost blackened the buds of Apricots to the core, and they were not more forward than they are now. We have forgotten to say, when adverting to the orchard-house above, that the frost has just crusted the surface of the ground and the surface soil in pots. We do not want the frost to do more for the pots, and, therefore, have placed a little litter over and round those not previously protected. Expecting frost on Wednesday night, the Strawberry-pots removed to the orchard-house had a sprinkling of rough hay shaken all over them to keep the soil and roots from being hard frozen.

Peach Trees under Glass.—Thinned-out shoots in the Peach-house, and stopped a good many, so as not to arrest root-action by taking away too much growth at once, looking out for a new shoot at the base of the one now showing fruit. As some of the young fruit did not seem to part with the calyx freely, drew the fingers over them, which was better than much syringing in the dull cloudy weather. As yet no insect of any kind has appeared. A few pans on the pipes are now kept supplied with soot and sulphur water. When the pipes are rather cool they have been several times damped with tea made from pouring hot water over the bruised young shoots. When used clear, weak, and fresh it makes a nice wash for syringing, the little prussic acid peculiarly suiting the Peach, and, unlike many another wash that leaves less or more of nastiness behind it, this leaves the nice aroma of confectionary custards. It must be used fresh, weak, and clear, or it will be apt to leave a

stain on the fruit. We once had the charge of a Peach wall that, after a most trying spring, became a moving mass in May, every shoot having its full colony of insects. The trees were freely disbudged, or rather dis-shooted, the fingers being drawn through the shoots left, to crush the insects. All the shoots removed were collected in apronfuls, and then were malleted or bruised, and thrown into a barrel, and about a dozen gallons of water, near the boiling-point, poured over them. There would be fully a couple of bushels of the shoots when roughly bruised. After standing covered up with sacks and mats for a couple of hours the liquor was poured off, and water added to make forty gallons, which were used to thoroughly engine the wall and trees about four o'clock in the afternoon. The liquid was used at a temperature of 120°. Next morning the trees were washed with clean water. In the afternoon the tea-process was repeated, and another washing of clear water next morning, and scarcely an insect afterwards appeared during the season. We have never found the wash so thoroughly efficacious as that one time, though we have often found it useful. This is only one of the many singularities about all insects. What will destroy them to all appearance at one time will scarcely injure them at another. We mention this circumstance because we frequently omit to use what we have close beside us, and which in many cases might be as effectual for our purpose as the tobacco and washes which must be purchased.

Two matters we deem of importance in Peach-houses and vineries, figeries, &c., where trees are in a growing state in this very changeable weather. The first is, to keep the temperature as low as to be safe when the weather is very dull, or when the frost is very severe. This rule may hold good unless when Vines are in bloom, but even then 5° lower will be better than a scorching heat in the pipes or flue. For instance, if the general temperature of a Peach-house was 55° at night, we would sooner see the thermometer down to 50°, or even 45°, than up to 60°, on such a night as that of Wednesday. This will save alike exhausting the energies of the plant, and making too great a demand on the coal heap. In dull days the rise in temperature should take place chiefly during the day, when there is most light, as was recently alluded to. Hence the importance of a little covering on the glass where it can be applied, or double roofs of clear glass with confined air between them, as then the heating medium requires to be less hot in severe weather, and it is always an advantage to be able to keep up the requisite temperature without greatly increasing the heat in pipes or flues.

Having had a great deal to do with pipes badly placed, and with a great deficiency of piping surface, we uniformly advise all who consult us on heating houses, not to be too economical in the quantity of piping, as that is only one outlay, whilst if there is a deficiency of piping there will be a constant extra outlay for fuel, so much of the heat going up the chimney, and the heat from the few pipes so very hot, is always unhealthy for plants, and just in proportion to their tenderness. We have seen the leaves of Ferns shrivelled up in a temperature of from 60 to 65° in winter, whilst in a similar temperature, and with merely a glass division between them, the same kinds of Ferns were as healthy as could be. There was no difference except this, in one division there were two pipes, in the other four. About five years ago a gentleman had two low houses, each separately heated, in which he wished to maintain an average temperature of 60° in winter. Five four-inch pipes were recommended for each. In a fit of economy, three pipes were placed in one house, and he wrote lately to say that the extra expense for fuel would have paid for the additional piping twenty times over, and he would have had a milder and more healthy heat.

The second point very apt to be overlooked, especially by beginners, is to guard against a strong heat in the heating medium and a powerful bright sun ever meeting together, and especially in frosty weather. As alluded to above, a fire may be put on in a dull morning, whether frosty or not, to raise the temperature in unison with the greater though dull light; but if the morning is frosty and promises to be bright, then the fires should be banked up or allowed to go out, as provided a little air at the top is given early, it will be safer to allow the house to rise 10° or 20° with sun heat, instead of giving much cold air, which one would be obliged to do, or shade the house if there was a strong heat in pipe or flue, and a bright sun telling on the atmosphere of the house at the same time.

Syringing.—Thanks to Mr. Weld (page 163) for so far corroborating what is said (page 149), of insect- being carried from

place to place on the clothes of workmen, and especially for the home thrusts at the constant use of the syringe. The pipes are so placed in our Peach-house that without the syringe we could not keep the trees clean, and perhaps the same remark would apply to Peaches under glass, and even out of doors they are refreshed by means of a good washing after a warm day. We used, in the case of Vines, to think that in early forcing a sprinkling frequently with the syringe was necessary to soften the buds. We question very much if a damp atmosphere would not do this better. For some time we have syringed late Vines little or none at any time, and never after they were fairly broken, except sometimes to give one good washing with clear water just after the fruit was set, to clear away all the remains of the bloom. The leaves never looked as if a syringing would do them much good. One reason, besides the saving of labour, in our case, was the next to impossibility of obtaining water clear enough for the purpose. Sprinkling the paths and floors seemed to give quite enough of atmospheric moisture, especially to late vineries. All these matters are worth discussing. Then there is no reason why a man should not hold his own opinions, and yet be large-minded enough to believe that another man may have what seem to him as good reasons for holding opinions quite different. There may be many roads to the same place, and every man may use that which he likes best, without finding fault with his neighbour. The world would be better every way if there were less of the infallible amongst us.

Stokeholes.—A number of inquiries have come to us, as to keeping water out of stokeholes, or getting rid of it when there, no doubt owing to the great quantity of rain. Where a stokehole must be rather deep, and unprotected by a shed, and the water rises nearly to the surface in general seasons, the bottoms and walls of the stokehole will have to be laid as carefully in cement, to keep water out, as if the intention had been to keep water in. Much, also, may be done by taking the surface water that falls a good way from the neighbourhood of the stokehole. We used to be very much annoyed by one stokehole in a pit-and-frame ground. A deep dumb well had been made to keep the place dry, but though 40 or more feet in depth, it soon became filled after a heavy rain, at least to the height of the bottom of the stokehole, and then there was a vast amount of work in emptying the well in order to drain the stokehole dry. We took all the surface water past the well into cesspools, and thence by pipes to a pond at a distance, made to receive it. This winter we have been troubled with water in a stokehole with a flap over it, not far from the front of a vinery-border, the drainage of which also goes into a dumb well. We could hardly think that the well could be full; we suspected surface water, and so arranged the fall of the ground that all the surface water would tend to a point the farthest possible from the stokehole. Still, after a heavy rain, we would have a foot or two of water in the stokehole. We think we have now found out the cause. A few yards from the stokehole there is a small cemented cesspool covered with a slate and then with gravel, in which meet the pipes that convey the water from several roofs before it is taken away by another pipe to a large outside tank. When that tank is nearly full of water, the water stands within a little of the top of the pipes in the cesspool. Two or three small cracks were found in the cesspool, and from these the water had slowly oozed until it found its way to the stokehole. Since the cesspool has been fresh cemented we have had no more water to speak of. Now, these may give hints to those troubled with water, and even rising above the furnace-bars. The best security against such moisture is having a drain from the bottom of the stokehole; but where that would be very expensive or next to impracticable, much may be done by taking away the surface water and cementing the walls of the stokehole. In ground where water will not stand there need be little difficulty.

ORNAMENTAL DEPARTMENT.

Cleared the centre of the walks from snow, and lightened some of the shrubs rather heavily loaded. The last snow-fall, though lasting but a short time, did a good deal of injury in this respect. In mild weather planting shrubs and Roses might be proceeded with. Dug up some beds and borders for flowering bedding plants, loosening the soil well at bottom, and mixing a little of it with surface soil, leaving it in ridges, and when frosty scattering some rotten hotbed manure over the ridges to become well sweetened, as the object is the reverse of raising a heavy Tainp crop, in which case the sooner the manure is buried out of sight the better.

Placed dry burnt earth and rubbish round Hollyhock stools

to keep frost and damp from injuring them. Dahlias wanted early should now be placed in heat. The best plan for those without frames is to let them bud in their winter cool quarters, and then divide with a good tuber, or piece of tuber to each bud or shoot. Then no better plan for them can be adopted than to fix on a piece of ground with a hard surface; place on that 2 or 3 inches of leaf mould or a little rotten dung and nice soil; on that place the divided tubers, from 4 to 6 inches apart, and then cover with from 3 to 4 inches of nice open stuff, rotten dung forming a part. In this the tubers will root freely, and about the end of May you will be able to take up the plants, with a large ball of rich earth, and transfer them to suitable holes in the flower garden. This is a far better plan than dividing the tubers at planting time, or even planting the tubers whole. The stems might want a little protection from frost in the beginning of May. From the middle to the end of March would be time enough to divide the tubers. Kinds wanted to be increased by cuttings should be placed in heat directly.

In cold pits, all such plants as Auriculas, Polyanthus, Wall-flowers, Stocks, Carnations, &c., should be kept dry, be protected from severe frost, but have air at all other times by tilting the sashes. If the frost continue for a week, or even less, mice must be looked after. We have known sad destruction effected in one night.

Calceolarias for bedding will sustain no injury from the damp if kept cool and air be given in suitable weather; we have not uncovered for two days, but we know the bed is cool. In addition to the little straw tied along the walls, hung a little more over from the wall-plate, or rather some litter, as not infrequently after carefully protecting the glass the frost enters through the walls.

In forcing-pits, propagating-pits, &c., kept up a nice mild heat, and as Hyacinths, Peonias, double Primus, Pinks, shrubs, &c., came into bloom, removed them to a cooler place, to prepare for the greenhouse or mansion.

Cinerarias do very well in rooms where there is not an excess of dry heat. Where near to fires, the leaves must be often damped to keep them healthy. Sudden transitions from cold to heat, or from a moist to a dry atmosphere, and *vice versa*, are to be avoided. For all plants in rooms where large fires are used, a sponging or damping the foliage will be the best mode of keeping them in health.

In greenhouses and conservatories, as well as in cold pits, too much care cannot be taken in avoiding spilling water when watering what is absolutely dry. In these frosty days it is desirable to confine the fresh air chiefly to the apex of the roof, and if there is much sun, to use little artificial heat until the afternoon, when the force of the sun is gone. In dull, muggy weather on the other hand, a brisk fire would be useful during the day, if little or none were required when the house was shut up at night. Were we close to a coal pit we would use more fuel in dull weather, and more air than we now do. Gardening differs from all mere mechanical undertakings in this, that constant watchfulness and observation are as essential to success as great abilities or great intelligence.

In such weather, see what was lately said of the position of Boronias, Leschenaultias, Pimeleas, Gompholobiums, Oxylobiums, &c., so that they may not stand in a draught of cold air, though fresh air shall be accessible. Florists' Pelargoniums will never do better than when standing on dry board shelves. Standing on earth, sand, ashes, gravel, or anything of that kind, moisture accumulates around them, and is apt to be condensed on them and form spot. Cinerarias in bloom, and Calceolarias coming forward, on the other hand, rejoice in a moist standing-ground. We have kept Cinerarias without an insect for the season, simply by standing them on damp moss.

Took the opportunity of the unsettled weather to put in a good many cuttings of Petunias, Verbenas, Lobelias, and Ageratums, and placed them in a bed prepared for them. The modes resorted to have often been described, and we dare hardly venture on details here, unless there were a number of beginners needing such information. We have at present lots of plants, &c., wanting hotbeds, but we cannot form the beds as yet. Next week we hope to describe a model amateur's pit for Cucumbers, Melons, plant-propagating, and general purposes.—R. F.

TRADE CATALOGUES RECEIVED.

Drummond Brothers, 52, George Street, Edinburgh.—Catalogue of Vegetable, and Flower Seeds, &c.

George Smith, Tollington Nursery, Hornsey Road, London, N.—Descriptive Catalogue of Florist's Flowers.

Archibald Henderson, Sion Nursery, Thornton Heath, Surrey, S.—Priced Seed Catalogue.

W. Hooper, St. John's Hill, Wandsworth, London, S.W.—Descriptive Catalogue of Vegetable, Flower, and Agricultural Seeds.

Francis Allum, Lady Bank, Tamworth.—Descriptive Catalogue of Dahlias, Chrysanthemums, and Bedding Plants.

COVENT GARDEN MARKET.—MARCH 3.

We have experienced a considerable falling off in our supplies this week, both home-grown and continental, in consequence of the altered state of the weather. Hot-house Grapes are much more scarce, Lady Downe's being over, and the samples of Barbarossa not equal to what they were. Apples and Pears consist of the varieties named last week. Of Asparagus there is a somewhat better supply.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

NORTH AMERICAN PLANTS (H. N. E.).—We do not know any North American nurseryman to whom we could refer you.

TOBACCO FOR PUNGICATING (A Constant Subscriber).—The Nicotiana tabacum is the best species to grow; but any of the other species will be effective. Any seedsmen can procure the seed if he has none in stock.

ESPERONE GRAPE (York).—Write to Mr. Fern, Rectory, Woodstock, Oxon, and ask for a graft. We shall be glad to hear from you on the subjects you mention.

FLOWER-POTS (S. Purelove).—Our correspondent wishes to know where he can obtain a quantity. Surely the makers would find it pay to advertise their wares.

LOBELIA SNOWFLAKE.—Have any of the readers of this paper grown Lobelia Snowflake from seed this year? I purchased a packet, and sowed three-fourths of it three weeks since, and not a vestige of a plant yet to be seen! Two acquaintances who also purchased 2s. 6d. packets, which have been sown a month, have not obtained a plant. One of these acquaintances is a nurseryman, and the other gardener to a nobleman. —NEMO!

IMPERFECT GREENHOUSE (A Regular Subscriber).—As the roof leaks, and the rain comes in round the door, it cannot be properly constructed. It is quite wrong to expect that the roof cannot be made waterproof. Call in some competent builder of such structures, and if he says the greenhouse is not built in a workmanlike manner, you will have a full justification for not paying until it is done better. We cannot give an opinion upon the legal points. By beginning to putty the laps the builders admitted that the glazing was imperfect.

SEED DRILL (A Subscriber).—Very simple, ingenious, and useful. It should be made of iron, and the handle arched like that of a plough to render stooping unnecessary.

TAN AND DUNG AS SOURCES OF HEAT (M. S.).—We have brought tan home fresh from the yard, and at once transferred it to the pit it was intended to heat; but we like better to bring it home and throw it in a heap in an open shed, and, if the weather is cold, to cover it over with litter, or anything else, until it begins to heat freely—then it may be used at once; but if time and labour can be spared, it would be better for tender plants if it were turned over again, the sides to the middle and top to the middle, &c. Then, in a few days, if the weather is such as to promote fermentation, it may be taken and slightly and equally trodden or beaten in its place; and provided extra heat be guarded against, the heat will be so sweet as generally to suit anything that likes a high temperature. Dung, nicely worked and sweetened, will do as well as tan for filling the inside of a pit for Cucumbers and Melons. We have not touched tan for a number of years; but one of the best combinations for such purposes, and also Pines, and for bringing on tender plants, is making the main part of the bed of sweet fermenting dung, and then covering with a depth of from 12 inches with sweet tan. Even the fumes from fresh tan are seldom injurious; but they are not so nice even to the smell as those from tan thrown in a heap to sweeten. When linares are required to add to or keep up the heat, it matters not whether tan or dung be used; only tan will be the safer, unless the walls are secure and care is taken of ventilation, for otherwise dung in the crude state might send its gases among the plants and injure them.

ICE-PLANT (Idem).—We have seldom found the birds meddle with the Ice-plant. Very likely it was the moisture in its stems that enticed them. The plant will stand hardly any frost. To keep it fresh and green all the winter it should have a dryish atmosphere, and a temperature of from 45 to 50. A few boxes may be grown in the usual way, and be moved under glass in October. For this purpose, if you sow in May it will be time enough. For summer use sow in March on a hotbed, and plant out in the beginning of June. It will require very little water in winter, but the soil must not be dust dry.

SHUTTERS FOR SHELTER (Idem).—"R. F." has not used wooden shutters for a long time. They are best made of three-quarter-inch seasoned deal, according to size framed beneath with narrow cross-pieces 2 inches wide, and 1 inch deep. If a strip 1 inch deep goes all round the outside the cover is perfect, as that will rest on the sides and top of the sash and enclose a body of air. The mode of making straw mats was given not long ago, and also the mode of making straw covers. The latter may be so long repeated. Take three pieces of wood the length of the sash to be covered, each 3 inches wide and from three-quarters to 1 inch thick. Place these so as to be of the width of the sash, one in the middle and one on each side. Then have cross pieces of wood of that width, say from 2 to 4 feet in length, according to the width of the sash, and each 2 inches wide and half an inch thick. Nail one of these to the three long pieces top and bottom, others in the intermediate space at about a foot apart. This makes the frame for the cover, and is intended to go next the glass. Reverse it after thus nailing it, and fill it neatly with straw. Fasten down one of these cross pieces at each end, and secure the straw by tarred string just above all the intermediary cross pieces. Five tacks for each string will enable this to be done expeditiously—one at each side piece, one in the middle, and one in the interval between the middle and side long piece. Without being made thus secure the straw would drop out in dry weather. Any straw will do, but wheat straw, drawn before it is threshed and the heads cut off, lasts by far the longest, and a cover thus made will be as serviceable in severe weather as three or four ordinary mats. Good deal would be the best to use; but "R. F." never had it, but worked up any old stuff that came in the way, and he has even cut up elm on purpose, that cost little more than the sawing, as otherwise it would have done only for firewood. Asphalt covers are very good when supported on frames.

MICE EATING CABBAGE PLANTS (Idem).—They and rats have cleared us out of our strong Cauliflower plants for the first crop in spring and summer. For rats, when everything else failed to entice them, we have found a number done for by mixing barley meal and arsenic with a little water, putting it where no domestic animal could reach it. We mixed it up with a stick, and put down the lumps with a stick. If the hand touches it the rat is too cunning to taste it, however hungry he may be. If water or milk is placed near the bait the sufferings of the rat will be short.

PIT FOR A VINERY (H. Vaughan).—Further than that you contemplate having an unheated orchard-house, 50 feet long, against a south wall, you give us no data whatever to guide us in giving you advice as to the making of a pit in such a house. If you tell us what is the height of the back wall, the height of the front of the house, and the width of the house, then we shall be able to advise you as to a pit, and whether a pit in ordinary circumstances would be desirable. For a mere unheated house in which you propose growing Peaches, Nectarines, Vines, and other fruits, we do not see what good you could do with fermenting dung in your pit. The simplest arrangement of such a house would be 12 feet in height at back, from 2 to 3 feet in front, and 12 feet in width, planting Peaches and Nectarines against the back wall, Vines up the roof at 5 or 6 feet apart, and Peaches on a low trellis in front, and a walk along the back. You would have more variety by planting out Vines, and Peaches and Nectarines, against the back wall, and either planting out the trees in front as dwarf bushes or growing them in pots. If your house were 12 to 14 feet in width, then you might have a walk all round, and a low pit in the middle, furnished with good soil, either for planting out or growing trees in pots. If you give us more data we shall be glad to oblige you.

BEDDING-OUT (A Lady Subscriber).—We think that your arrangement of beds of shrubs, and bedding plants will look very well. If we suggested a change, it would be to put a band of dwarf scarlet Geraniums, or the Centaurea candidissima round the centre bed of Aucuba; and then, instead of piecing the four beds 13, 14, 15, 16, we would ribbon or band them thus—13, 16, Heliotrope, Aucuba floribunda Calceolaria, and then Bijon Geranium; and 14, 15, Crystal Palace Scarlet Geranium for centre, Aucuba floribunda round it, and then Lobelia Paxtoniana. Your mixed Asters will scarcely be good enough for 17 and 18; better have mixed Verbenas, or ribbon and line them in contrast with 15, 12, and 16.

CONSUMING SMOKE (J. Mackenzie).—We know of no cheap system of consuming smoke. If the coal is only put on at the front of the fire, close to the furnace-door, the black or carbonaceous particles are chiefly cut rid of as the smoke passes over the brightly burning portion of the fire behind.

HANUM SEED.—Gentlemen wishing to try to cultivate this Palestine plant may have a few seeds, by enclosing a stamped envelope, with their address, to W. Wanklyn, Esq., Bury, Lancashire.

GEOOTHERMAL BED (Suburban).—In our No. 143, New Series, you will find a description of the geothermal bed at Welton Place, near Daventry. You can have the Number if you enclose four postage stamps with your direction.

DILYTRIA SPECTABILIS FORCING (Country Curate).—The causes of the failure are insufficient top heat, and the plants not having been previously established in pots and prepared for forcing. Keep the plants in the greenhouse until after they have flowered, giving them a light and airy situation; and when frosts are over remove them to a warm open situation out of doors; plunge the pots until July, and then remove them to a south aspect, and give no water except to prevent the foliage flagging. The plants will go to rest in good time, and from the time of the foliage decaying they must be allowed at least six weeks' rest. To make them flower at Christmas, which is very early, they should be plunged in a hotbed of 60 or 65 in October, and be gradually withdrawn from it by the end of the month. This will make the roots active. The plants should then be placed in a house having a temperature of 50 from fire heat, and in a fortnight increase the heat to 55 at night, allowing a rise of 5 on dull days, 10 on those which are cloudy with clear intervals, and from 15 to 20 on clear days. In these temperatures, with a moist atmosphere, gentle bedewing overhead, sufficient but not excessive waterings at the root, plenty of light, and abundance of air on favourable opportunities, your plants will flower by or soon after Christmas, but the bloom will not be nearly so good as on plants started at a later period. If the plants are in small pots and require potting, do it immediately after flowering, using a compost of turfy loam two-thirds, leaf mould one-third, and a free admixture of sand. Provide good drainage.

FORCING RHEUBARB (Idem).—We are at a loss to account for your failure in this, for you seem to have gone the right way to work. We find that by taking the plants up and placing the roots in soil, usually in a Mushroom-house, we can have very fine stalks in a month or six weeks. The temperature is from 55 to 60, and uniform, of course, from the position. We have also potted the roots, covered them with an inverted pot, and placed the pots in a temperature of from 55 to 60 at night, and we have thus had stalks for use in six weeks. We think your failure due to an insufficient amount of heat.

VINE-GROWING FOR WINE-MAKING (Vitis).—The price at which foreign wine is now to be obtained in this country renders the cultivation of Vines under glass for the purpose of making wine unnecessary and unprofitable. The varieties are too numerous for us to specify them, unless you want to know the sorts that produce some particular kind of wine.

ORCHIDS FOR A CUCUMBER-HOUSE (J. L. Stockhouse).—The following three are recommended for your Cucumber-house, which you say is at work all the year:—*Arides odoratum majus*, *Calanthe vestita*, *Phalænopsis grandiflora*. *Dendrobium nobile* may also be grown in the Cucumber-house, and removed to the conservatory when in flower. The house (70 to 75 without sun, and higher with) is too hot for *Odontoglossum*.

VARIEGATED DIANTHUS (W. D.).—We have never seen this plant in a variegated form before, and should much doubt whether, from the nature and habit of the Dianthus, the variegation would remain permanent. To judge of its merits the plant must be seen.

FUNGUS ABOUT VINE ROOTS (A Constant Reader).—The white mould is the mycelium of some minute fungus. The other specimen is not a fungus, but the fibrous root of some plant. They are not injurious to the Vine.

VINE CULTURE (R. & W.).—As you have "everything to learn," we recommend you to buy "The Vine Manual," which you can have free by post from our office if you enclose thirty-two postage stamps with your address. After reading the directions it contains for growing the Vine in a greenhouse, if you need any question answered we shall reply freely.

ROCK PLANTS FOR NORTH ASPECT (M. E. H.).—Alpines rejoice in sunshine and dislike shaded, damp, close places. Your situation would answer admirably for Ferns. You may also plant *Ambrosia deltoidea*, and its variety *grandiflora*; *Arabis aloda* and *alpina*, *Cerastium tomentosum*, *Saxifragas juniperina*, *granulata*, *cotyledon*, *arctioides*, *nizoon*, *azoides*, *cyndularia*, *hypnoides*, *umbrosa*, *palmata*, and *Rhodi*; *Statice alpina* and *sinuata*, *Silene alpestris*, *Trientalis europæa*, *Vinca minor*, and its variety *plena*; *Vinca major*, and its variety *elegantissima*, and *Vinca herbacea*, *Sedum acre*, *kamtschaticum*, and *spurium*, *Pulmonaria angustifolia*, *officinalis*, and *grandiflora*, for the base only. *Pinguicula vulgaris*, *Lotus corniculatus flore pleno*, *Linaria cyndularis* and its variegated variety, *L. origanifolia*, *Hepaticas*, and the varieties of *Primula acutifolia*, for the lower parts. These would be likely to do moderately well.

CAMELLIA PLANTING OUT-DOORS (Idem).—A white Camellia would not, we think, do well out of doors, either as a standard or trained against a north wall in a cold valley in Sussex.

PLANTS FOR TOWN GARDEN (M. A. E.).—The best of all to flower in May and June are herbaceous *Pionias* and *Paeonia montana*, *Dianthus cruentus*, deltoides, and fraxans; *Dilytra spectabilis*, and its white variety; *Pulmonaria officinalis*, *Trollius europæus*, *Tulips* in great variety, *Convallaria majalis*, and the gold-striped, pink, and double varieties; *Polygonatum vulgare*, *Cerastium tomentosum*, *Campanula aggregata*, *carpatia*, *marialis*, *pusilla*, and its white variety; *Bellis perennis aeneoblobia*, *Dodecatheon elegans* and *media*, *Doronicum caucasicum*, *Iberis saxatilis* and *I. sempervirens*, *Lythrum roseum superbum*, *Narcissus poeticus plenus*, *Polythrums* in variety; *Saxifraga aizoides*, *umbrosa*, and *Andrewsii*; *Silene Schaffa*, *S. alpestris*, *Polygonatum cornutum*, and the variegated variety; *Phlox frondosa*, *Nelson*, and *verna*; *Orobis vernis*, *Antirrhinum* varieties, *Columbine*, and *Ajuga alpina*.

HERBACEOUS PLANTS (Idem).—You will find just such a list as you request us to give at page 72 of the Number for January 2nd.

SELECT POMPON DAHLIAS (Nemo).—The following are very good free-flowering varieties:—*Crimson Beauty*, *Multiflora*, *Rosette*, *snow Rose*, *Goldfinch*, *Little Wonder*, *Little Janty*, *Little Darling*, *Little Arthur*, *Dr. Webb*, *Gold Pheasant*, *Little Mistress*.

FLOWER SEEDS (A. B. Wycombe).—It is impossible to answer so wide a question. All flowers probably might be improved by judicious crossing. We cannot ask for cuttings.

NAMES OF FRUITS (*Lemon-Toothing*).—Verulam Pear. (*E. H.*).—Uvedale's St. Germain Pear.
 NAMES OF PLANTS (*C. S. G.*).—*Solanum marginatum*, or White-edged Nightshade. It is a native of Palestine. (*A. A.*).—2, *Asplenium bulbiferum*; 3, *Nephrolepis*; 4, *Asplenium flaccidum*; 5, *Ferns japonica*

6, *Dentzia gracilis*; 7, *Asplenium marinum*; 10, *Pteris cretica albo-lineata*; 12, *Nipholobolus lingua*. (*A. W. Willd.*).—*Scilla peruviana*. (*Calcearia*).—You must send better specimens if you wish to have your Ferns correctly named.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

A DAY AT LINTON PARK, KENT.

THE SEAT OF THE VISCOUNT HOLMESDALE, M.P.

FOR some years I have had always a stereotyped reply to the question: "Have you been in many of the counties of England?" It was this—"I have been in all of them except Kent and Cornwall." Poultry has now led me into Kent, and, therefore, only Cornwall remains as yet utterly unseen and unknown. Ever since I saw the prize birds of the Viscountess Holmesdale at the Bath and West of England Show, held at Clifton, in 1864, I had felt a great wish to see her ladyship's stock in its entirety. That wish has recently been gratified; for a letter having reached me in which Lady Holmesdale informed me that "it would give her great pleasure to show me her poultry," and I being desired to take an early opportunity of going into Kent, as the family were about to remove to London for the season, I proceeded to Linton Park forthwith.

It has not been a very good season for birds, owing to the great fall of rain; in many poultry yards and walks the fowls almost needed stilts in addition to legs to keep them out of the water. (N.B.—Were I a fowl I would be a Malay—*i.e.*, if it were always such weather as we have had this winter.)

I start for London the day the Queen opens Parliament, for of course it will be fine (it was). As I passed through Berkshire I pitied the poor folk there, and registered this verdict concerning their county—"Found drowned." In London I met with a well-known and well-knowing poultry fancier and judge, who told me, after I had informed him whither I was going, "You will see poultry to perfection at Linton Park." With expectations still higher raised I get up next morning very early to proceed into Kent, as it is Lady Holmesdale's wish that I should see her fowls in the forenoon.

The first train, then, finds me at Charing Cross Station, and I look upon that very gorgeous Station and feel thankful that I own no shares in that line. Ah! what have we here? A restored Queen Eleanor's Cross in a station-yard. Poor King Edward was unlucky in his site; at any rate he did not foresee what an unquiet place it would prove in after ages. But no, it is not a restored cross, but a bran-new cross in front of a spick-and-span gaudy station. Bad taste surely, besides a waste of money. I feel no reverence as I look upon this entirely new cross, erected on, perhaps, the spot where Queen Eleanor's body rested for the last time before interment, just 575 years ago. Had it been a re-storation I should have felt reverential; and all new, not placed, as surely it might have been, in some quiet nook, but where every vulgar 'bus and cab rattles by and draws up close to it, just on the spot where, in front of an inn the horse-block was commonly to be found—"my gorge rises at it." And yet how one respects King Edward, that good husband, who, not in the first heat of a bridegroom's passion, showed such love to his spouse; but he, an old husband, went to such cost and care for his old wife, the mother of fifteen children. 'Tis the newness of the cross and its position jars upon the sense. How different it is when the new and old are brought side by side, as in the case of the railway that runs close by Furness Abbey; there, there is food for much reflection. There, on one side, is the crumbling ruin, the evidence and token of

the highest civilisation of its day; and the flashing railway train type of the civilisation of the present day. There in the Abbey were gathered together the few books and few readers of a whole district. There were the men who could plan the rich tracery, erect the pillars, and bid the arch span the space between. Surely the dark ages were blind in many respects; but they certainly were not stone blind. And in the Abbey, now so old, were the men who cultivated flowers and herbs with thought and care, and, mayhap, were proud and careful of their breeds of fowls when others were indifferent. And there close by is the nineteenth century railway station and electric telegraph. But I am growing desultory.

Off for Marden, for two hours or more of travelling. I like, in going from London, to watch how gradually, very gradually, on this Kentish side, town melts into the country. First after actual streets come, to use the happy phrase of Cowper—

"The villas with which London stands begirt,
 Like a swarth Indian with his belt of beads."

I love to think of the retired citizen, or the man of business, who scarcely more than sleeps in the country air, enjoying when able his rural home and his garden, perhaps his live pets. Then after villas come the patches of building ground and the one-half-finished house, the very last link to the town, till a few miles further and it is actual country—real farm-houses, unmistakable labourer's cottages, and yes, surely, that is an old country mansion. How bright green is the grass, and why, the stations have creepers growing up their iron supports; all looks rural; not the blackened look of a Lancashire, but the pure look of a thoroughly agricultural county. But surely those must be hop poles piled like a number of giant's pikes in tent-like patches all over the fields on both sides of me. Oh! had I been a teetotaller, how my heart would have ached. By the way, as teetotallers are the greatest consumers of animal food in the country, for he that drinks nothing but water eats much more than other men, ought not the Chancellor of the Exchequer in these cattle plague days to tax every teetotaller extra? I think so, and wonder the thought of such a tax has not come into the fertile brain of Mr. Gladstone.

Verily Kent is a beautiful county, how emerald green its grass; how well cultivated and garden-like its fields; and that ridge of pleasantly-swelling hills to the left of me, running on and on, how agreeable to the eye. I do not wonder that "the men of Kent" are proud of their county. It is such an old-inhabited part of England. It was for ages the key to the kingdom: it had the post of honour because it had the post of danger. Shakespeare says of it—

"Kent, in the Commentaries" Cæsar writ,
 Is term'd the civil'st place in all this isle:
 Sweet is the country, because full of riches;
 The people liberal, valiant, active, wealthy."

Then, too, the antiquity of its families is noticed by Lord Macaulay, who says of the signal fire telling that the Spanish Armada had been sighted in the Channel—

"And eastward straight, o'er wild Blackheath, the warlike errand went,
 And roused in many an ancient hall, the gallant squires of Kent."

How, too, a common danger must have bound together the people of Kent. They could see, while other folks of other countries could only hear of, the old enemy's country, France. Should there have been an invasion, in days preceding steam, the French would most likely have landed in Kent. Hence,

Wordsworth's address to the men of Kent, in a sonnet dated 1803—

"Vanguard of liberty, ye men of Kent,
Ye children of a soil that doth advance
Her haughty brows against the soil of France,
Now is the time to prove your hardiment."

Then, too, the situation of Kent in other respects is a proud one. Above it the Thames, along whose waters has for ages been borne the wealth of the world; the Straits of Dover beneath it, up which how many a great personage has come to land in Kent. Well may you be proud of your county: what thoughts are conjured up by even the words, Thanet, Dover, Canterbury. Kent is, indeed, a grand historic county.

With my mind full of these thoughts, and enjoying myself to the full, I reach Marden Station, a little place where few trains stop. I soon found my way to the village inn, and in the snugest and cleanest of inn parlours sat a crust of home-made bread and cheese, on what Frank Walton would have called, "a fair white linen cloth," and I drank a glass of most excellent beer, so good, perhaps, because brewed in the land of hops. I drank it to the health of all the good people of Kent. Linton Park is, I am told, four miles distant, and eschewing that stuffy thing on a fine day, I mean a fly. I mount a dog-cart and am driven by "mine host" himself. I admire the horse, and am told it was in the Crimea. Lucky horse to get back safe and sound! Probably your rider did not.

"That is Linton Park I imagine," said I, pointing to a long white mansion showing plainly on the brow of the opposite hill. A fine position and a fine frontage, a centre with wings far-reaching. Part of the park hangs on the slope below, while evidently the ground rises sharply at the back, or the timber is very fine, as the tops of the trees, of apparently an avenue, overtop the highest part of the house. I am right, it is Linton. On we go, the Crimean horse has some go in him. What a pleasure there is in a drive in an entirely new country, the air so fresh to the lungs, and everything, every feature of the country, fresh to the eye.

But I am nearing Linton Park. To the left of the park fence is a model village formed of substantial cottages, built in pairs with good gardens. This is to me a very pleasant sight. Landowners often say, "You cannot build good cottages that will pay even a decent interest for the money so spent." Granted, but I hold that such building is yet a good investment for money in certain localities, and under certain restrictions, and that, indirectly, such cottages will pay. Thus, if a farmer can offer a good house, making that dearest thing to an English man, and still more to the Englishwoman of every grade, a comfortable home, he will secure from emigration a respectable labourer; and if on the estate there be good cottages, a good class of poor will be permanently established, and this will be a gain to the owner. I have usually found the doubtful character, who poaches a bit and pilfers a bit more, living in a poor wretched cottage. But while I am moralising, there is the church—happy vicar of Linton with such a respectable-looking village, and a fine church too—and here we are at the park lodge. A pull, a stiff pull, a gate opened, and passing by a newly laid-out garden with a broad straight walk leading from the house to the church, in a minute or more we stop at the chief entrance of the mansion. A few seconds alone in a drawing-room admiring the view from the window—the terraced garden, the park, the lake, and far-stretching view of the Weald of Kent, and then Lady Holmesdale is with me, and ready to show me her fowls.

First to the poultry-yard properly so called, to the right of the house. Here I find solid buildings with spacious yards in front enclosed with wire netting. First came Dark Brahmas, but cared for at Linton chiefly for their sitting virtues. While looking at them, Martin, Lady Holmesdale's well-known poultryman, devoted to and thoroughly understanding his business, made his appearance. Wee to the fancier whose poultryman, woman, girl, or boy, is not so devoted. A poultryman, like a poet, is not made but born to it—i. e., born with a strong love of live things. Next Dorkings, then Golden Hamburgs, and living with them an odd Turbit Pigeon, a pet of Martin's. Yes, pet love meets one everywhere. Years ago I found the owner of a bird shop keeping a Linnet as a pet, as if he had not birds enough and noise enough in the way of business; but so it is, doctors have their pet patients, often, God bless them for it, the poorest, and pet cases usually the worst; but I never heard of a lawyer having a pet client, perhaps the touch of parchment chills the blood and freezes the heart. "One touch of parchment makes all lawyers kin." But to pro-

ceed. Martin, with voice and scattering food, invites some wanderers near, among them a rose-combed Dorking cock fresh from his triumphs at Rochdale, and a truly magnificent bird he is.

It may be well to state that Lady Holmesdale, though possessing many other varieties of fowls of first-rate quality, chiefly values her Dorkings, and her taste runs for the rose-combed, as rarer and handsomer. Those who have never seen her ladyship's Dorking cocks can scarcely imagine their great size. A Dorking cock at Linton Park is quite a different bird from even a rize Dorking at small shows. His size approaches the majestic, and that and his fine points quite raise him above the run of "they varner's fowls," as I once heard Dorkings called. A peep at other birds enclose I near, all of merit—some Spanish, also just come home from Rochdale, and then we retrace our steps to the south front of Linton, and are off, joined by a gallant general, to look at the poultry kept in different parts of the park. One glance in passing, but only one, at the beautiful garden; that and Lord Holmesdale's head gardener, our Mr. Robson, I am to see after luncheon. We verge towards Linton church, and on a high bank among some low shrubs find another Dorking cock, a young one, and pullets. It is the effort at Linton to breed the fowls of as dark a colour as possible, and although I have a lingering prejudice for the Silver-Grey, yet I must own that such dark birds as seen here are very beautiful, and are said to weigh heavier than any Silver-Greys that can be bred. Wherever I found poultry in the park, there was near each group a moveable wooden house, like a tiny cottage without a chimney. I did not look into one, being told there was no particular arrangement inside; they are painted of a dark colour, and are on low wheels, so that they can be easily moved. If a run becomes tainted or is too damp, away go fowls and house.

Chatting pleasantly we proceed up the avenue leading to Maidstone. I was all the while a beguiling poultry recruiting-sergeant to the General, being determined to enlist him in the valiant army of fanciers. Away we stroll, talking politics and—poultry, enthusiastic on the subjects of Governor Eyre and—cocks and hens. Having proceeded some distance, walking beneath those lofty trees, which had caught my eye on my way from Marden Station, we find more Dorkings and their wooden home. Theirs a kind of Australian life compared with the denizens of the wire-fenced and trim poultry-yard; the inhabitants of the latter wealthy stay-at-homes, while the others are younger and poorer relatives who emigrate to make their fortune. I preferred this cockerel to the one before seen, his points were better and his hackle clearer, for even in Dorkings I do not like a black-tipped hackle any more than in Duckwing Game cocks.—WILSHIRE REXTON.

(To be continued.)

EXPENSES AND RETURNS OF POULTRY KEEPING.

THESE is, I am sorry to say, a mistake in my account, though not the one your correspondent believes. I find I have understated my expenses. I ought to have put down the food at 221 12s. 4d., or about 8s. 3d. weekly, instead of the amount stated. This I believe to be the only mistake. I had not at any time, as I think your correspondent understands, 489 individual birds. The actual number of fowls I possessed I set down each week, and added them at the end of the month, and thus obtained my grand total for the year, which I divided by 52, giving me my weekly average of 113. Take, for instance, the month of June:—

Week ending	Cochins.	Fowls.	Ducks.	Chickens.	Aviary Birds.
June 3rd,	7	33	4	70	10
" 10th,	7	36	7	70	20
" 17th,	7	40	7	70	20
" 24th,	7	33	7	70	20
July 1st,	7	32	7	80	20
	35	177	35	350	100

Thus the actual number of individuals in the last week was 116; some weeks I had fewer birds, and, as I stated originally, my average number of mouths fed was 113 per week.

With regard to the other questions, the 48 7s. 6d. is entirely for stock bought in 1865. I have not entered the value of the stock I had at the beginning of the year. I should put it at about 48 more. With regard to the cost of labour, I fully expected that if that were taken into consideration the balance would be on the wrong side; but I think 1s. per day is too much to charge, as I do so much myself. I think poultry alone are very profitable; but in my case it must be remembered

that aviary expenses are included (I cannot at present separate them), and though I have sold aviary birds well, their profits are uncertain. In your first answer to my questions, you ask what extra or accidental food the fowls obtained. They mostly have free range of the shrubberies and grass fields, and some have access to the stable, pig, and cow-yards. There are no grain stacks. They share with the pigs and dogs what scraps there may be from the house. The only extra not entered is a little hempseed, which I gave as an occasional luxury.—C. E.

GAME BANTAMS.

THE "WILTSHIRE RECTOR" tells us that his plan in life is never to enter into any controversy, but openly to state his opinion honestly formed on any subject that lies in his way. This is all very well in private matters, although there it will not bear examination; but when an opinion is given in public, and affects the interests of others, a man is clearly bound to defend his opinion, or to hold his tongue. It is not my intention to involve the Rector in a controversy. It so happens that I do not agree with him, and so far as he is concerned I am content to use his own words, "Doctors differ, that is all."

It is another matter, however, with Mr. J. Crossland's letter, quoted by the "WILTSHIRE RECTOR," because it comes from a practical and experienced man. He says, "From a single yard in Yorkshire there have been sold upwards of £180 worth of Game Bantams in twelve months. The breeder has also taken himself, I see from this Journal, from December 1864 to December 1865, four silver cups, cup and second at Darlington 1864, cup at Thorne for two years, 1864 and 1865, cup and second at Darlington 1865, cup at Birmingham, given by subscribers, in 1865. . . . I have only crossed once in ten years, and I gave £5 5s. for the bird—first at Birmingham, first at Plymouth, and first at Liverpool." Surely Mr. Crossland knew without the help of THE JOURNAL OF HORTICULTURE how many prizes the breeder he alluded to had taken.

At an average of £7 a-pen—no bad price for birds so easily bred—it would require about twenty-six pens, or seventy-eight birds, to make up the £180. Game Bantams must be easy indeed to breed, their powers of production must indeed be marvellous, if, between January, 1864, and this time seventy-eight birds could be bred from one stock which would realise such prices! Will Mr. Crossland venture to say that all these birds were in a *bonâ fide* manner bred by the breeder and exhibitor in question? Was nothing added or purchased from other stocks? Was he never at a loss for birds to make up a pen, and glad to fall back upon the assistance of others? If not, then he is indeed a prince of breeders, and fortunate must Mr. Crossland be in his confidence. If it be so easy to breed birds of this kind, how does it happen that the greatest part of this breeder's birds were "sold to our well-known exhibitors in the Game Bantam classes?" Surely they could not have wanted to buy.—A CHESHIRE PILE.

BEING a constant reader of your Journal, I have noticed all the correspondence which has resulted from the "WILTSHIRE RECTOR'S" "First Impressions of Bingley Hall." If you will allow me a little space I will endeavour to give you a specimen of my experience in the breeding of Game Bantams, which has extended over a period of five years. At the commencement I claimed three pens at different shows, and put them out on separate walks, and bred from them, fully expecting they would produce some first-class birds. However, I was doomed to disappointment, not one first-class bird came from the whole lot. I tried another year, with the same result.

A short time afterwards I was present at a show, and admired very much the pen which had taken the first prize, and on referring to the catalogue to ascertain if the price was one I could afford to give, I found I knew the exhibitor well. The remarks of the fanciers present were, that he must have some good birds, from the fact of his name appearing so often in the prize-lists. However, as I fully intended buying the pen if possible, I took an early opportunity of calling upon him, and requested to see his Bantams, and he at once complied, remarking, however, that his best were from home. The day being fine we walked down to his runs, and I there saw birds which threw my own at home completely in the shade, and I at once determined to clear my own stock off, which I did, and, as in the drapers' advertisements, at an immense sacrifice. After viewing the whole of his stock, I concluded a bargain with him, and bought a cockerel and four pullets on the express condition that I sold him all the chickens I had to spare

from them at a guinea each; so you may judge that the price I gave him was not a very small one. However, he gave me his word that they would breed as true to feather as the partridge in the stubble.

When they commenced laying I collected all the eggs, and set four Game hens with seventeen each, from which I obtained forty-nine chickens, and reared forty-two—thirty-one pullets and eleven cockerels. On their being ready I advised the person of whom I bought the fowls to come over and inspect them, and not wanting many myself, and also having others coming on, I agreed to sell him, as per agreement, thirty-seven of the birds, and had the satisfaction of receiving £38. On meeting with him some time afterwards, he informed me that out of the lot he had made in sale and prize-money the handsome sum of £80! which, of itself, I submit, is a sufficient guarantee of their worth.

If breeders would only be careful in selecting their stock, and not purchase from so many yards, but breed from some well-known strain, mark the eggs from each hen, and send their chickens to separate walks, they would at once find which were the best hens to breed cockerels and pullets from. I am of opinion that a great many breeders do not take notice of that. I should be glad to see a few remarks from some of our oldest breeders and exhibitors on this subject; but I hold the opinion of the "WILTSHIRE RECTOR," that Game Bantams are easy to breed good if proper care and judgment be exercised.—A WEST YORKSHIREMAN.

ARTIFICIAL INCUBATION IN CHINA.

M. DAERY, French Consul at Han Keoo, in China, has just published an interesting paper in the "Bulletin de la Société d'Acclimatation" on the process employed by the Chinese in hatching eggs artificially. The places where this trade is practised are called Pao-jang; each consists of a mud hut, 3 yards in height, exclusive of the roof, made of tiles; the inside of the hut measures 8 by 4, and its entrance is situated due west; the north-east wind is provided against by a layer of straw applied to the wall; the door is made of planks, and measures 1 yard by 2. Light is admitted through four apertures in the roof. Within, there are eighteen brick stoves, 2½ feet high, along the wall, and close to each other. Each of these stoves supports a large earthenware dish, sunk into the brickwork and just above the fireplace; and inside this dish there is a basket of nearly the same shape, resting on a layer of ashes about 2½ inches deep. It is in this basket the eggs are to be hatched; 1200 in number are arranged in three layers, and the whole covered with a cane lid half an inch thick. Nine of the stoves are lighted at a time, but only eight have eggs, the ninth being intended to regulate the temperature of the room, which must be maintained the same throughout. The combustible employed is charcoal, and the temperature in the basket never exceeds 38° centigrade (100.4° Fabr.) The eggs are shifted five times during the twenty-four hours—viz., four times during the day and once during the night, the upper layer going to the bottom, and the bottom becoming the middle one.

On the fifth day a small hole is pierced through the door, and by the pencil of light penetrating through it each egg is examined, in order to ascertain which of them are in course of incubation. On the twelfth day the eggs are taken out of the baskets and arranged on shelves above the stoves, provided with layers of straw, 2 inches thick, and mats over them. Upon these the eggs are laid, with a cotton quilt nearly 3 inches thick between each layer, and another quilt just above, the whole being well secured by means of a thick straw rope to prevent the air from getting to the eggs, which are regularly shifted as before, five times a-day. As soon as the eggs are taken out from the baskets, the fires are put out in the stoves which have been used; the nine other stoves are lighted, and the process re-commences with a new batch of eggs. On the 21st the former lot is hatched, yielding about 700 chicks for every 1000 eggs. Every egg costs 6 sapeks, and each chicken obtained is sold for 14; the sapek being the 150th part of a franc.

HIVES.

IN your Number of the 20th ult. Mr. C. F. George describes a plan for making the square straw hives, and he says that my "native hives" seem "exactly like" his. Now, as my hives can be purchased (see advertisement in your Number of the 20th ult.) I ought, perhaps, not to notice Mr. George's communication, but, as our object is doubtless the same, the en-

encouraging the bar and frame system by rendering the hives obtainable at a lower price, I will describe the mode of manufacture according to my plan.

The accompanying sketch is that of the frame I use; it is made of half-inch deal, the sides 3 inches deep, the cross pieces only 2 inches deep, and set in the sides 2 inches from their ends. This frame is 14 inches square from external corners to external corners. I have other frames made on the same plan for nucleus, hexagon, or for any number of bars as required.

The sewing the straw (and my man never uses a ring), is conducted from end to end, not along the side pieces, and when the end of the side is arrived at, the frame is lifted out, turned one-quarter round, and replaced, for the sewing to be carried along the next side, the cross pieces being set back for that purpose. This moving of the frame keeps the inside dimensions perfect; the side pieces, with a little beating of the straw, give a flattened surface to the inside. When finished the hive retains its shape admirably, is perfectly uniform in diameter, and I have never noticed any bulging or conical form whatever with this frame. The maker can turn it in his lap; there are no inconveniencing wires or laths; and any degree of tightness can be exercised that is desired, a point upon which in reality the goodness of the hive depends. My man now uses nothing but cane. I would recommend Mr. C. F. George to purchase one, from which, if he can obtain any hint, I am sure he is heartily welcome.—J. H. BLOUNT, M.D., *Bayshot, Surrey.*

When taking steps for raising queens from the brood of my pure Italian mother, upon the 20th of May, I introduced her with a considerable number of her subjects into a frame hive furnished with several frames of empty brood comb, selecting for the centre three combs consisting in a great measure of drone cells, as I wished, if possible, to rear and preserve a number of drones for the fertilisation of queens late in the season. Towards the end of June these combs were well filled with drone brood, and as the honey season began to break up early in July, I was apprehensive lest the workers should begin to cast out the immature drones. By Mr. Woodbury's advice I removed the queen, placing her again at the head of a new colony.

LIGURIAN BEES.

The bees in the parent hive at once constructed royal cells; but these having been all excised before they came to maturity, the bees were unable to take any further steps for supplying themselves with a new monarch. They continued, nevertheless, to work pretty nearly as well as usual, but were rather more irritable than their neighbours; still, had I not been acquainted with their internal history, I should not have supposed that they were both destitute of queens and young brood.

On the 4th of August I supplied the hive with a frame of bees and brood from the young colony founded upon the 6th of July, and governed by the pure Italian queen, which was now a populous and flourishing family. Many royal cells were at once founded upon this comb, but, owing to the unsettled wet weather then prevalent, I did not inspect the proceedings of the bees very closely.

On the 15th of August (the eleventh day from the time when the bees were supplied with the brood), I found one cell open, from which a queen had evidently emerged. "The shades of night were falling fast," and I was unable to do anything further that evening; but as no time was to be lost, early next morning the hive was again inspected, and I found five royal cells were already torn open, the work, as I then supposed, of the senior princess. I soon detected a queen with her head and nearly the whole of her body in one of the worker cells; having carefully excised the piece of comb, I gently broke open the cell into which the queen had retired, and having ascertained that she was very beautifully marked and perfect in all respects, though rather below the average size, I at once removed the comb containing the royal cells (seven of which were still intact), and returned the queen to her native abode.

On Saturday, August 19th, I found this queen lying in front of the hive almost dead, and feared that the hive was then queenless. In the afternoon, to my surprise, I found another queen, of rather a dark colour, lying in front of the hive, and still able to move a little, proving that she too had only recently received the mortal wound. On opening the hive I soon detected a third queen perambulating the combs. It is evident that in this instance at least three queens at liberty co-existed in one hive for three days. The victorious queen was duly fertilised, but did not begin to lay before the middle of September.

I have upon several occasions introduced strange queens (both virgins and matrons), into my nucibomb hive when it contained a queen regnant, and in every instance the stranger was gradually surrounded and imprisoned by the workers; but the legitimate queen has never been in any way molested or interfered with. Supernumerary queens are, I know from actual observation, frequently disposed of by the workers; but the queens are in all probability often allowed to engage in single combat for the supremacy, and this was doubtless the way in which the matter was settled in the hive alluded to, as neither of the dead queens presented the usual disfigurement observable in those which have perished from encasement.—J. E. B.

OUR LETTER BOX.

JUDGES AND JUDGING IN SCOTLAND (*Scotchman*).—The remarks were general, and do not require a defence of the Paisley Show. Such general remarks direct attention to the subject, and if they are not well-grounded are best allowed to pass unnoticed.

COCHIN CROSSED WITH DORKING (S.).—Now that the hen has sat and brought off a brood, the taint will most probably cease. It prevails, as in the Turkey, for many more than one egg.

VICTIOUS GANDER (W. R.).—Your parting with him will not prevent the Goose continuing to sit. Perhaps you are not aware that a gander very usually shows a violent temper whilst the Goose is incubating. It is his mode of showing his anxiety to defend her during her own defenceless state. The violent temper ceases when the goslings attain a large growth.

WIRE FENCING (*Carolina Duck*).—Any wirework manufacturer advertising in our columns will give you the information you need.

TUMOURS ON TURKEY'S HEAD (J. F. S.).—Open the tumour with a pair of very sharp scissors. Remove the matter, and wash the cavity thoroughly with warm water. Then draw the edges of the skin together very loosely with two or three stitches by means of a needle and thread. No ointment is needed. Perform the operation in mild weather. Give a tablespoonful of castor oil, and on no account give stimulants, such as "Cayenne pepper and chopped onions." The food, rather, should be cooling—mashed potatoes and a little barley meal, and plenty of green food. If you send to this office five postage stamps with your address, and order "Bee-keeping for the Many," you will have it sent to you free by post. Peafowl lay in spring; usually beneath some bush near the tree where they perch. The "Poultry-keeper's Manual," with coloured plates, price 7s. 6d., gives full directions for keeping all kinds of poultry, treatment of diseases, &c. You can have it from our office.

SATINETTE PIGEONS.—Mr. Noye informs us that he did not exhibit Satinets at the Birmingham Columbarian Society's Show. Mr. Noye's name appears, however, as having done so in the printed catalogue.

FOOD FOR BIRDS (BENJAMIN PARROQUET (M. S.)).—To keep the bird in health give it canary and hemp seed, about one-third of the latter to two-thirds of the former; bread soaked with water, squeezed dry, and given cold, fresh every morning; occasionally one or two chillies as a stimulant; and for a change give it a little scalded rice sparingly, also a small quantity of water to drink in a small tin pan to hold about two tablespoonfuls—not sufficient to wash in. The bird is very fond of fruit in season, such as apples, pears, &c. By no means give it meat or fat to eat, or bones to pick.

HONEY HARVEST FOR 1905.—Mr. S. BEVAN FOX informs us that the amount of his last year's honey harvest in the concluding article on "Apian Notes," at page 175, was understated. It should have been 330 lbs., instead of 230 lbs., as there given.

OPENING A WOODBURY-HIVE—SPRING FEEDING (A. R.).—I have already examined all my stocks and seen either the queen or young brood in each, but can scarcely be said to have commenced spring feeding, although I have everything ready for it as soon as the weather becomes favourable. Birmingham being so much colder than Exeter, I think you had better defer all these operations a few weeks longer.—A DEVONSHIRE BEE-KEEPER.

THE DYSENTERY (B. S.—D. C. A.).—There can be little doubt that when dysentery exists among bees the insects themselves are in a morbid condition, which may arise from various causes. Dysentery is profuse in quantity, of a dark colour, and emits a very offensive smell. Dr. Duholth, a distinguished German apianist, gives the following description of his analysis of the excreta of healthy bees, in which he found three ingredients. "1. *Remains of Pollen*.—I boiled the excrement in caustic potash lye slightly diluted. After filtering, I washed the residuum in hot dilute muriatic acid. What was left after again filtering could, from its insolubility, be only the remains of pollen. It appeared under the microscope like an indistinctly granular mass. 2. *Uric Acid*.—I immersed the excrement in concentrated sulphuric acid, in which uric acid remains undecomposed. After carefully decanting the liquid from the remaining carbonaceous mass, I added water, and then washed the precipitated matter in water. I now added one drop of liquor ammoniac and one drop of muriatic acid. On heating, the mass assumed a purplish hue, the characteristic reaction of uric acid. 3. *Hippuric Acid*.—I boiled some excrement in caustic potash lye. After filtering, I added dilute muriatic acid, and obtained a precipitate which proved to be composed of uric and hippuric acid. According to an approximate estimate the excreta of bees consist of about one-third uric and hippuric acid, and the residue of indigestible pollen."

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 51.0°; and its night temperature 34.0°. The greatest heat was 67°, on the 15th, 1838; and the lowest cold 17°, on the 17th, 1846. The greatest fall of rain was 0.70 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

THE ROOTING OF PEARS ON QUINCE STOCKS —PARADISE STOCKS.

HAVE read your remarks on the rooting of Pears on Quince stocks from the junction of the graft with the stock when it is buried, and am able, after many years of observation of such

subjects, to assert that you are perfectly correct.

It is now about twenty-four years since I formed a plantation of two thousand Louise Bonne Pears budded on the Quince. They grew and bore well; but as some of them were planted before the ground was trenched, when that was done the earth was raised above the junction of the buds with their stocks. This did not seem to affect the growth of the trees for some few seasons; but after a time, from five to seven years, I observed a marked difference in some of the trees. They made shoots of great vigour, and ceased to bear such fine fruit as the others. The few fruit produced were green, small, deformed, and much spotted with large black spots. This induced me to have the earth removed from the bases of the trees, and I then discovered that the vigorous-growing trees had made large roots from the graft, and that the Quince roots were rotten and perfectly elete. The following season I observed that these vigorous-growing trees were more or less affected with canker, and the shoots dead or dying from their tips to half way down their length. My curiosity was excited as to why this should take place, and I had some of these Pear roots followed with the spade. They were found to have run through the staple—a sandy loam 20 inches deep, and to have penetrated the clay to a depth of upwards of 6 feet: they had numerous ramifications, but were destitute of fibres, seeming as if they had hard work to do—i. e., a long way to go to pick up indifferent food. On examining trees of the same kind, standing in the same row, with the junction of the graft with the stock just clear of the surface of the soil, the Quince roots were found close to the surface and very fibrous. I should mention that they were bearing fine crops of very handsome clear-skinned fruit, were in a very healthy state, and so different from the Pear-rooted trees as to appear a different variety; yet they were all Louise Bonne Pears. I immediately had the earth carefully removed from the bases of all the trees, taking up and replanting some that were buried too deeply, and have had no trouble since.

I must confess that this experience of the ill effects of the deep rooting of fruit trees made me a more strenuous root-pruner and remover than ever, and I have never forgotten the lesson.

In closely observing for some years the Pear trees I

have alluded to, I was much struck with a curious fact. In spite of all my care, my labourers in digging the ground would, through carelessness, cover the junction of the grafts with earth. In looking over the trees in summer, I was soon made aware of this by seeing some of the trees making shoots of great vigour, and on examination the Pear roots were found thrusting themselves into the earth with great determination. The curious fact was, I could never find any fringe of fibres on the graft, or any small roots. There were in all cases but one or two (the former the more frequent), large bare roots, the commencement of which I never could see. As far as I remember, I found some of these Pear roots not so far advanced as to have killed the Quince roots: I then had them cut off with a saw, the tree staked, and it was restored to its fertile state.

Some large trees of the Vicar of Winkfield Pear, now twenty-five years old, and in a healthy state, have rooted from the graft. They have not suffered in health as did the Louise Bonne, but they are very large and unmanageable.

Ever since the experience gained as I have related, I have been very careful to keep the junction of the Pear graft with the Quince stock just clear of the surface of the soil, and have told my friends to do the same. Your correspondent Mr. Scott is, I presume, a young cultivator, and has some experience to gain.

I must not omit to state what so strongly impressed me at the time—the power of what we should call in animal life instinct: let us call it “vegetable instinct”—the term is not inappropriate. The trees while deriving their support from the Quince roots were confined in their growth; yet they patiently awaited their opportunity, and as soon as “mother earth” by contact tempted them with a more abundant supply of food, they gladly put forth their natural feeding powers—their own roots, and took advantage of it. The subject was full of interest. Again and again I turned to my half-reasoning trees, and felt more than ever the wondrous incomprehensible power of Nature. There is something trite and not by any means new in what I have written as to the power of the instincts of plants. The observing cultivator may have them under his eye daily; but I never remember to have been more forcibly impressed with what to me seemed vegetable reasoning than the rooting of my Pears from the graft: they “bided their time” so cleverly.

With regard to the Pommier de Paradis, not “Pomme Paradis,” Mr. Pearson is right, and Mr. Scott, well—decidedly wrong. There are many trees and shrubs that brave the severity of a continental winter only because they grow under a powerful sun, and have well-ripened tissue. This is the case in France with the Pommier de Paradis, which Mr. Scott should have seen. There is some confusion in the terms used to designate the Apple stocks called Paradise stocks. I have hitherto in all that I have written called the Pommier de Paradis the “French Paradise,” and have warned cultivators against employing it except for pot culture. The English Paradise, still grown by the stock-growers in Surrey, is a very distinct

sort, but of the same relative vigour as the Doucin of the French cultivators: consequently I have tried to make them bear one name, and have called this stock the English Paradise or Doucin, hoping that we should settle down to two names, both distinctive—viz., the French Paradise (Pommier de Paradis), of but little value here, and the English Paradise, comprehending all the vigorous-growing varieties of the Doucin.

There are in France probably eight or ten sorts of dwarfing Apple stocks called Doucins, some of them with small leaves and a dwarf habit, approaching in character to the French Paradise, but harder—one of these may be the "Pomme Paradis" of Mr. Scott—others more or less vigorous. As far as I have experienced, almost every department in France has its Doucin stock. The best of them is that sort which approaches nearest to our English Paradise stock. Our climate requires a vigorous, hardy, surface-rooting stock—surface-rooting is the alpha and omega of fruit-tree culture in England.

The slowness with which a thorough knowledge of fruit-tree culture is acquired can be known only to those who have passed their lives in carrying it out. The knowledge of fruit-tree stocks, so slightly appreciated in England, is a life study. The changes brought on by grafting, the stocks to be employed, the experiments in grafting that may be tried, and which as described in your columns amuse me by the zest with which they are told—Pears on Thorns, and Figs on Thistles—the Apple on the Pear, and the Pear on the Apple. By the way, an American friend told me the other day that the finest Pears he ever saw were from grafts on an Apple tree. The tree, as usual, did not live many years.

To return to Apple stocks. One feels half vexed that the name "Paradise" has been applied to them; it is so absurd, but, like other ancient things, it cannot now be changed. The Pommier de Paradis is evidently from the east, is identical with the Dwarf Apple of Armenia, and may there, by some eastern tradition, have been pointed out as the Paradise Apple, and thus have travelled to the west with its imposing name. It must, however, be acknowledged that the fruit of the Apple tree bearing this name would scarce tempt a very hungry boy living in Clare Market.

Among these surface-rooting Apple stocks the Burr Knot has a high character. Its habit is stout, healthy, and robust, so that when grafted it gives to the graft a healthy prolific character. It may be propagated from cuttings made of shoots two years old, but it is slow in rooting. The English Codlin will also strike from cuttings and become a surface-rooting stock, but it does not form a healthy tree.

The great desideratum in garden Apple-tree culture is to employ a robust-growing but surface-rooting stock. The English Paradise and some of the robust-growing kinds of Doucin are of this nature; but the nearest approach to the Burr Knot, and consequently to perfection, is No. 1, a stock raised here from seed forty years since, it is presumed from the Nonesuch Apple, as its shoots are full of spurs and knots like that sort; yet, much like the Burr Knot, it makes stout shoots as thick as one's finger in one season, is most robust in its habit, and yet roots very freely at the surface, and by doing so promotes a most healthy vigour in the graft. Of this very remarkable stock, which French pomologists are in raptures with, it is intended to propagate here 100,000 a-year, and its name is the Nonesuch Paradise.

No. 2, another seedling raised at the same time, has the same tendency to make roots at the surface, is almost equally vigorous, but is quite distinct. Its shoots are smooth and dark in colour, like some of the best varieties of Doucin; but its leaves are broader, and it is more vigorous than any kind of Doucin. This will be distinguished by the name of Rivers's Paradise.

No. 3 is another seedling Paradise stock, raised in the same year as those above described. This is a hardy healthy-growing stock, more humble in its growth than the French Paradise, and calculated to make trees of very diminutive growth.

No. 4, also a seedling raised at the same time, is the most dwarf of all fruit stocks, and is a perfect miniature Apple tree, forming itself into a bush only a few inches in height. As compared to the French Paradise it is as an ant to a bluebottle fly. It is, of course, only a curiosity. I have mentioned it merely to show the illimitable variations of trees when domesticated—i. e., under cultivation for a long series of years; and it reminds me of the curious Pear which I am employing as a dwarfing stock—the Nain Vert, which when grafted on a vigorous stock never makes an annual growth of more than 2 inches.

The history of my seedling Paradise stocks illustrates what

I have advanced as to the length of time required to obtain a thorough knowledge of fruit-tree culture. Twenty years ago the English Paradise was well known, but it was rarely planted and but little understood. It is forty years since I raised my seedlings. I kept them because I was interested by their tendency to root at the surface of the soil. It is only within the last twenty years that I have been impressed with the value of Nos. 1 and 2, the impression slowly but steadily increasing, receiving an occasional filip from clever French cultivators, till, at the present time, I believe they will supersede all other Apple stocks for garden trees, giving a healthy, robust, yet prolific character to the varieties grafted on them.

Miller seems to have been well acquainted with the French Paradise (Pommier de Paradis); and I commend the following extract from his folio dictionary, 1759, to the notice of Mr. Scott, whom I have not the pleasure of knowing—it may make him a wiser man. "The Paradise Apple hath of late years greatly obtained for stocks to graft or bud upon; but these are of not long duration, nor will the trees grafted upon them ever grow to any size, unless they are planted so low as that the Cyon may strike root into the Ground, when it will be equal to no Stock, for the graft will draw its Nourishment from the Ground, so that it is only by Way of Curiosity [I quote capitals as printed], or for very small Gardens that these Stocks are proper, since there can never be expected any considerable Quantity of Fruit from such Trees. These Trees have been much more esteemed in France, where they were frequently brought to the Table in the Pots growing with their Fruit upon them; but this being only a Curiosity, it never obtained much in England, so that the Gardeners do not propagate many of them here at present."

Miller alludes to our English Paradise as follows:—"There is another Apple, which is called the Dutch Paradise, much cultivated in the Nurseries for grafting Apples upon in order to make them Dwarfs, and these will not decay or enker as the other, nor do they stint the Grafts half so much; so are generally preferred for planting Espaliers or Dwarfs, being easily kept within the Compass usually allotted to these Trees."

I hope I have in this rather lengthy article thrown some light on Apple stocks. There is almost as much to be said on Quince stocks, of which there are several varieties, some of them very unfavourable to the Pear graft, and making the trees short-lived. It must be thirty years since I received from M. Leroy, of the "Grand Jardin," Angers, one plant each of all the sorts of Quince he possessed. In the course of a few years I discovered that the Angers Quince, "Cognassier d'Angers," was the most easy to propagate and the most favourable to the growth of the Pear. I made this known in that part of France, and it soon became the most popular of all. It deserves to be so. There are still too many other kinds of Quince employed in France and Belgium for stocks, some of which are most unfavourable to the growth of the Pear graft.

In conclusion, I must recommend your numerous readers, when they plant Apples on the Paradise stock, to avoid the French Paradise, which, as Mr. Pearson justly says, will not do well in our climate; and this seems to have been well known upwards of a century ago, thanks to our good old friend Miller. Those who assert that the French Paradise—the Pommier de Paradis, or "Pomme Paradis" of Mr. Scott—has done and does well in Scotland and other places with cool moist climates, have not planted the true sort, and probably do not know it.—THOS. RIVERS.

Allow me to say a few words with regard to Pears grafted on the Quince. In 1858 or 1859, I forget which, I had three small Pear trees, grafted on the Quince, planted deep enough to cover the graft. This was not done for any particular purpose, but more by accident than anything else. Last year, when leaving my old place, on taking them up I found one had rooted strongly above the graft, both the others slightly. I have also seen Pears root in this way several times, and I am surprised that Mr. Scott should think it necessary to use such very strong language in denying what many gardeners must know to be true. As to the Paradise stock, it may be as hardy as Mr. Scott says, on this point I say nothing; but I know from experience that the trees are easily injured by frost here, and very liable to be attacked by insects (aphis) in summer. Out of ten trees, five were killed by frost, and two by

* I need scarcely to point out how this illustrates all that I have said about Pear trees rooting from the graft.

insects and the summer heat; but I am bound in justice to say that the others have made very good stocks, and the Apples grafted on them have done well.—J. H.

THE COILING OF VINES.

It was not till I had waited some time after the appearance of Mr. Rivers's illustrated communication on this question that I took it up. I wished, and waited to see, others offer their experience, as I was well aware that many could state important facts very similar to those I related at page 83, and with which Mr. Rivers deals in his usually acute way.

Passing over the opinion of Mr. Rivers's venerable French friend, upon whose experience, as it seems to me, and not on his own, Mr. Rivers recommends so confidently the layering or coiling of Vine stems, I will shortly refer to the remarks which Mr. Rivers makes on the facts which I stated in my former communication; and this I do, not for the sake of inaugurating a controversy with Mr. Rivers or any one else, but still further to assist in bringing out what may be regarded as the soundest practice on this not unimportant point of horticulture. I will still leave the circumstances connected with the experiments I have already related to be compared with Mr. Rivers's theory.

He states that I "confound the coiling of the shoot of a Vine lightly covered with soil with the layering of a Vine deeply;" but my comparison was not between the layering of a shoot deeply, and another that had been or was to be lightly covered. It was between those that I had layered 8 inches deep and the directions given by Mr. Rivers's misprint to cover them 10 inches deep, so that on that particular point I was reasoning from premises furnished by what I supposed to be his and my own figures; and from what I am about to state it will appear that the correction of the misprint does not alter the deductions or the correctness of the opinion formed in the course of my own experience.

Mr. Rivers asserts that to bury the stem of a Vine 8 inches deep is to place it too deep to receive any benefit from those grand sources of life—light and heat, consequently it puts forth no roots. I will not here controvert the idea that light is more favourable than darkness to the formation of roots, any further than to say that I agree with our great physiologist in believing that darkness is more favourable than light to the formation of roots. Heat has, beyond all question, much influence in producing roots, and in the case of the experiments I detailed this only tends to strengthen the deductions that I made—namely, that it is unnatural and injurious to layer the stems of Vines in the soil.

The Vines which I layered across the border from the back to the front wall, and those I planted, and the stems of which were layered from the centre of the inside border, where their roots were fixed, to the front wall, were all layered in below the hot-water apparatus, which runs 2 feet from the front wall. Close to the surface of the 8 inches of soil which covered the Vine stems rested the pipes. I need scarcely say that at the point below the pipes the stems had by far the most warmth, much more than where the whorl of roots was produced, close to the cold front wall, yet this did not cause the stems to emit roots where there was most heat, but where I conceive it to be most natural—near the union of the Vine with the border. Now, I have always found that Vines planted in the usual way send their roots into the soil heated by the proximity of pipes or flues, and in these cases at least Mr. Rivers's theory as to the Vines being buried away from the influence of heat being the cause why they did not emit roots on "every inch of stem" does not hold good in my experience, for the roots were produced close to the front wall where the soil was coldest and shaded from the rays of the sun. As to the greater amount of light and heat which a Vine covered 2 inches deep with fine soil receives over one covered 8 inches in the inside of a warm vinery, I could not really determine; nor does this seem to be any more than a theory with Mr. Rivers.

In reference to the other case of which Mr. Rivers says "that the stems of the Vines were most probably too deeply covered, and shaded from the direct rays of the sun by the front wall: under such circumstances they could not put forth roots," facts are very different from surmises or guesses, for it was just in the shade of the front wall that the strong whorl of roots was produced, exactly below where the stems entered the soil. My experiment with the pot Vines may be accepted as a "great mistake" in the same sense that many other experiments may be so termed; at the same time I cannot, with my

experience of the depth at which Vine roots will act, and act vigorously, accept Mr. Rivers's theory in this case either. He says that the results I stated arose from the roots being buried to the depth of 15 inches, and the Vines were ruined by their roots being placed out of the influence of light and heat. Surely Mr. Rivers is not in earnest when he affects to tell Vine-growers that the roots of Vines will not act at a depth of 15 inches, because they are out of the influence of light and heat! I would simply ask if ever he ripened Grapes in April from Vines having their roots entirely in an outside border without bottom heat, and thatched over with a layer of dry leaves and straw? and if he has, whether he thinks under such circumstances their roots were under the influence of light? But this is not all, the border in which I plunged the pot Vines in question was more than usually open, and heated from beneath with air-drains.

As to roots not acting at a greater depth than 15 inches I will leave that question to all those who have either put an addition to the front of a Vine-border or lifted the roots of Vines that have been planted for any length of time. Have they not found them down 4 or 5 feet deep, where light and heat from above could not have any influence on them? The reason of these Vines not doing well was not the wants of which Mr. Rivers speaks; and their not doing well cannot, from anything that has come within the range of my experience, or that Mr. Rivers has advanced, be attributed to the want of light and heat at their roots. I feel perfectly confident that had they been buried much deeper, but not having soil in contact with their stems, they would have done as well as their contemporaries. If roots of Vines are so fond of light why do they not root up to it? as they do when covered over deeply with manure or leaves, still more coiling them from light, although they will not do so when the border is not mulched.

I am inclined to look upon the coiling as a delusion in more respects than this. It is practised with the view of increasing the roots of Vines; but is not root-vigour more dependant on the amount of healthy foliage that the Vine is allowed to make than on burying in the ground what Nature designed should climb into the air, and induce the emission of roots at fresh points? I feel convinced that if a fresh set of roots are thus produced the old roots will be deserted in the long run; and if so, what has been gained? Not anything; but the result will be injury to the Vine, to say the least of it, for the time being. In the order of Nature the Vine will come to depend on the roots formed at the junction of the Vine with the border, thus proving the correctness of the theory that the descending sap is interfered with by placing the liber of the stem where only roots were intended.

If I might suggest to Mr. Rivers that he leave a portion of the Vines he proposes coiling as they are, for comparison with those coiled, his experiment would then be much more satisfactory, and if spared till the International, "may I be there to see." This quotation prompts the thought that this hobby may prove as unruly as John Gilpin's horse.

With these remarks I leave this question in the hands of others who may feel inclined to favour us with any experience they have had, and leave future experiments to be related when carried out to their results, as I purpose to do in the case of some I am now making.—D. THOMSON.

MEARNS'S SYSTEM OF COILING VINE SHOOTS.

If I may judge from a short article in the "Florist and Pomologist" for this month, the coiling of a Vine shoot *without a root*, after the system of Mearns, which was much written about some years ago, has been confounded with the coiling of a rooted Vine.—T. R.

[A drawing and description of Mr. Mearns's "coiling system" are in the "Vine Manual," published at our office.]

NOMENCLATURE OF GARDEN PLANTS.

SHALL I be taken for a Goth if I plead the cause of the ladies, the country gentleman, and the general public, in favour of a natural English system of nomenclature for all the vegetable kingdom, instead of the present hybrid classical system?

Very few know the meaning of the names used, and I am sure that equally appropriate scientific names could be devised in our own tongue, while for all ordinary purposes the common popular English names are sufficient. The puzzle caused to most people by a seed or plant catalogue is immense; and I see

no reason why seeds should be catalogued as *Ipomœa*, *Bellis*, *Yugates*, *Mathiola*, &c., when they are well known as *Convolvulus*, *Daisy*, *Marigold*, *Stock*, &c. Cannot we have an English nomenclature established which shall be intelligible to all? —D. S.

HUNTROYDE PARK.

(Continued from page 478.)

For the last two months the weather has been very unfavourable for the alterations which have been commenced, nevertheless, much has been done; a great portion of the draining has been completed, and a large belt of trees that constantly enveloped the kitchen gardens, shutting out from these the sun and air, has been grubbed up. Owing to these trees the produce of the gardens had for many years past been of a very inferior kind. The ground the trees occupied is now being trenched and will be taken into the kitchen garden, the outer walls of which will be removed on the south side to a distance of 50 yards. Here a sunk fence has been commenced which will extend about 600 feet along the south front of the kitchen garden. A little below this there is a public footway which is at times thronged with people, especially on Sundays; and as the family cannot at present enter the kitchen garden without crossing this path, my object in making the sunk fence is to hide the gardens as much as possible from public view. The fence will be 6 feet deep, 16 feet wide at top, and 10 feet wide at bottom, and a walk 8 feet wide will be made at the bottom of the sunk fence. The soil excavated will be all thrown out on the south side; this will form a bank which will completely block out the view from the public road. To increase the height of the back of the bank all the large tree roots have been dragged down and placed parallel with the sunk fence; they will also form a good drainage for the bank, which will be made very ornamental on the south side, and as the road above mentioned is one of the principal approaches to the Hall, my intention is to plant an avenue of *Cedrus deodara* on each side of it about the centre of the fence. A tunnel will also be made by which access may be gained to the walk at the back of the sunk fence. This tunnel will be about 50 yards long, and will be commenced in the pleasure ground on the south side of the carriage road, and by this means the family will be enabled to pass from the pleasure grounds or the Hall without being overlooked by the public.

In the pleasure grounds extensive alterations will be made. These, however, will not be commenced for some little time yet, my object being to concentrate the most of my attention on the kitchen and fruit gardens for the first year, so that they may be progressing while my attention shall be engrossed with the alterations in the pleasure grounds.

I may here state, in order to more fully illustrate the operations now in progress, that the present flower garden, which is at a considerable distance from the spot where the mouth of the tunnel on the south side will be situated, is to be converted into a pinetum. This will be divided into eight quarters by eight 12-foot walks, all converging to a raised mound in the centre. Here eight magnificent perspective views will be obtained by cutting through the wood in each direction. I propose clearing a space of about 30 yards for each walk, levelling the sides, and planting them with choice specimens of such coniferous trees as will be likely to thrive in this cold, wet, and smoky climate. Three of the walks will cross a trout stream which can be made very beautiful without much trouble. A large reservoir will be made at some distance above this point, and a series of cascades and waterfalls will be constructed down the brook. These are intended to form an important feature in the beauties of Huntroyde after it has undergone the various alterations in contemplation, and which are necessary for giving prominence to its natural advantages.

One of the three walks mentioned above as intended to cross the brook in another direction, will bring us out exactly opposite to the mouth of the tunnel. At the north end will be a flight of steps leading from the walk at the bottom of the sunk fence. Here a field about three acres in extent is being drained, preparatory to its being converted into a fruit garden. Through the centre of this field, in a straight line from the tunnel, will be the principal approach to the kitchen garden. A main walk about 15 feet wide will be made, and on each side of this walk will be a grass plot 20 feet wide, in which will be cut out beds for Roses, bedding plants, fine-foliaged plants, &c. At the back of these, on each side will be formed a bank about 5 feet high, and on the centre of the bank will be planted an

evergreen hedge of some kind, probably Holly. Then there will be a 15-foot slope on each side of the hedge. The slopes towards the broad central walk will be for ribbon-borders. Here I intend to use five shades of colour, which will give 3 feet of each shade. The number of plants required for these borders will be about 30,000.

Another walk, 10 feet wide, running parallel with the sunk fence from east to west, will intersect the walk leading from the tunnel. This walk will be about 300 yards long, commencing at the east end in what is now the old kitchen garden. On the right hand is a range of good houses which have been used for a variety of purposes, they are in good condition and only want modernising. They are about 90 feet long. In one of them I have a fine lot of Pines, and some excellent pot Vines, supplied by Mr. Meredith; the other two contain a miscellaneous collection of Pines, stove plants, &c. During the spring these houses are to be altered, and they will thenceforth be used as vicinies.

At the end of this range, and parallel with the walk, a site is set apart for a fine range of three-quarter span-roofed houses. The range will be 164 feet long by 20 wide. This brings us across the present kitchen garden, where we enter the field before mentioned. In the front of these houses will be a sort of terrace-wall, on which will be placed ornamental vases for plants. On the opposite side of the walk, in front of the houses, will be a border for mixed flowers, such as Roses, Dahlias, herbaceous plants, &c.

After passing through the kitchen garden we enter the field, or what will be the fruit garden. Here the mixed border will be continued on each side of the walk, after passing the houses, till we come to and pass across the main central walk. The rest of the walk westward I purpose covering with wire trellises in the form of an arch. This will be for training Apples, Pears, &c., on, and at the end of this walk will be a summer-house. The effect when looking from this point I think will be very pleasing. At the back of the borders on each side will be planted a row of fruit trees to be trained as pyramids. The four quarters, divided by the walks above described, will be laid out in beds of about 30 feet each. These will be thrown considerably above the general level of the ground. In the centre of each bed will be planted a row of pyramidal-trained trees, on each side of these a row of bush-trained trees, finishing off the edges on each side with a row of cordon-trained trees. The whole of these raised fruit-tree borders will be made parallel with the walks, and the sloping banks at the back of the ribbon-borders will be planted with Strawberries, that facing the east will be planted with the latest-fruited kinds, and that facing the west with the earliest, and the sloping bank on the garden side of the sunk fence will be set apart for Alpine Strawberries.

I will now go back again to the kitchen garden for the purpose of describing a range of forcing-houses built in a very creditable and workmanlike manner by the Messrs. J. & L. Birtwhistle, of Padham, near Burnley. Although the range was only begun about the last week in November, we shall in another fortnight have it completed, and the weather during the greater portion of the time has been very unfavourable. The range is a three-quarter span, 141 feet long and 16 wide, inside measure, and divided into five compartments. Two of these will be devoted to the growth of Pines; one to Cucumbers; the fourth to Melons; and the fifth will be used as a propagating-house. In this house I have had constructed what I shall call Will's model propagating apparatus. Living near a manufacturing town where almost anything can be formed out of iron, I have been able to surmount a difficulty which has always tried me sorely. I may now truly say I live in an iron age. Well, the difficulty I have hitherto had to contend with has been how to construct a tank suitable for propagating-purposes—I mean a tank that a hot-water pipe shall pass through immersed in water. I have had several constructed in this way; they have been built on firm and solid walls, the bricks laid in cement, the bottom and sides covered with Portland cement and tiles, and on these, again, another coat of Portland cement with a proper quantity of good sand in it; yet after all had been finished, as soon as the pipe that passes through the ends of the tank became heated by the hot water circulating through it, it expanded, and then the cement cracked, away went the water, and instead of a nice moist heat I have been obliged to do with a dry heat, which is not at all favourable for propagating-purposes. A tank of this description I had built at Woodlands, near Stanmore, some years ago, when I had a controversy with my old friend

the late Mr. Beaton, when he was so strongly advocating the sand-and-water system of propagating, and it was the most successful I ever saw before or since. Now living, however, near a town where castings of any description can be had, I made a sketch of what I wanted, gave it to Mr. Birtwhistle, and he quickly made a pattern which was sent to the foundry, and in a short time, not more than a fortnight from the time the idea suggested itself, he came my propagating-pans. They are 2 feet wide at the top, and about 13 inches wide at the bottom, 8 inches deep, and 10 feet long. Very shortly I will give an open section of the end of the house, showing the position of the propagating-pans when fixed, the method of working them, &c. I have also had a lot of iron slabs cast for covering fine tops; these answer remarkably well, they will throw off a large amount of heat with one-fifth of the firing that it takes to heat a flue covered with ordinary tiles, and I am not sure whether they will not supersede hot-water pipes in many cases.—J. WILLS.

(To be continued.)

ROYAL HORTICULTURAL SOCIETY.

MARCH 6TH.

FLORAL COMMITTEE.—The unfavourable state of the weather had its effect at this meeting, both in respect to the number of visitors and that of the plants sent for exhibition. The exceedingly cold atmosphere made exhibitors very cautious in sending their plants, but, notwithstanding, there were many good things to be seen. Major Trevor Clarke sent a specimen of *Coburgia miniata*, an old plant, not often seen in bloom, producing a head of handsome, tubular, red flowers, 3 inches long, the segments of the mouth of the tube marked with dark green; a special certificate was awarded it. Mr. Daniels, Swyncombe House, Henley-on-Thames, contributed cut specimens of a new *Bougainvillea*, named *splendens*, brighter and more intense in colour than *speciosa* and *glabra*, and an earlier-flowering variety. From a note sent with it, it appears that with this and the other *Bougainvillea* was a succession of blooms of these decorative plants may be had throughout the year. A first-class certificate was awarded.

Messrs. Lee, Hammersmith, exhibited eight fine plants of *Ancuba japonica variegata*, bearing clusters of handsome scarlet berries. A special certificate was awarded them. J. Bateman, Esq., sent cut specimens of Orchids for distribution, and for these a special certificate was also awarded. Rev. G. Cheere, Papworth Hall, sent two large pots of *Anna Boleyn Pink* in full flower, for which a special certificate was awarded on account of meritorious culture. Mr. Young, gardener to Mrs. Barclay, Highgate, sent a large specimen of *Oncidium sphacelatum*; and Mr. Veitch a new *Lycaste* from Guatemala, supposed to be a good variety of *L. Deppoi*; also *Illicium religiosum*, an old plant producing pale yellow flowers. From Messrs. Garaway came cut specimens of *Amaryllis*—viz., *Ariel*, a pale variety with broad white bands, and *Miranda*, a deep red.

Messrs. E. G. Henderson, Wellington Road, exhibited a large collection of *Cyclamens* containing many varieties, some of them producing semi-double flowers; among them *C. com.* and *Atkinsii* in bloom and album; these dwarf specimens covered the surface of the pots with their sweet miniature flowers. A special certificate was awarded them. From the same firm came *Pelargonium Pink Stella*, very promising, but not in a condition nor at a season for its merits being decided on. It was requested that it should be sent again. Mr. Brown, Elmton Hall, was awarded a first-class certificate for a cut specimen of *Rhododendron Aucklandii*, a large handsome white flower.

From Mr. Elliot, Lillieshall, came a cut specimen of seedling *Rhododendron Duchess of Sutherland*; and from Mr. Allis, Gunton Park, Norwich, a cut specimen of a *Rhododendron* with very handsome white bell-shaped flowers, with deep red markings at the base. This beautiful specimen arrived too late to be noticed. It was subsequently determined to be *R. argenteum*. W. Wentworth Buller, Esq., sent cut specimens of hybrid *Rhododendrons* and *Rhododendron Jenkinsii*, also a plant of *Lælia furfuracea*, an Orchid seldom seen in flower. A special certificate was awarded for these interesting specimens. Mr. Pilcher, gardener to S. Rucker, Esq., Wandsworth, brought twelve cut flowers of *Camellias*, all of them first-rate flowers of great beauty; among them were a superb specimen of the double *Camellia reticulata*, *Cup of Beauty*, *Reine des Fleurs*, *Lavinia Maggi*, *Valtearedo*, *Countess of Orkney*, *Princess Sophia*, *Mathotiana*, *Eximia*, and *Elegans*. A special certificate was awarded them—a distinction which they well merited. Mr. Pilcher brought also cut specimens of two beautiful *Lycastes*. Several plants came from the Society's gardens, among them were *Cattleya Trianaei* var., collected by Mr. Weir; a well-grown specimen of *Dendrobium speciosum*, to which a special certificate was awarded; and another variety of *Odontoglossum* collected by Mr. Weir. It is to be hoped that at the next meeting Mr. Pilcher's example may be followed, and that an opportunity will be given the Fellows to note down the best varieties of *Camellias* in cultivation. It is not difficult to bring cut specimens of this beautiful flower, and it is very desirable to make it more popular.

FRUIT COMMITTEE.—The subjects exhibited on this occasion were

few, as might be expected at this period of this season. From the Rev. M. J. Berkeley's garden in Northamptonshire, came an Apple supposed to be Northern Greening, but more highly coloured than that sort usually is, even when long kept; and from Mr. Fleming, Cliveden, Scarlet Nonpareil in excellent preservation, and some very good Apple jelly. Mr. Christie, Avington House, near Winchester, sent two seedling Apples, one of which, somewhat resembling Court of Wick, was of very good quality, and it was requested that a greater number of specimens should be sent for tasting on a future occasion. Mr. H. Turberville, Pilton, Barnstaple, exhibited a seedling Grape, said to hang exceedingly well, but of which the Committee could form no opinion from the small portion sent, and the bad condition in which the berries were.

SCIENTIFIC MEETING.—W. Wilson Saunders, Esq., F.R.S., in the chair. After the awards of the Floral Committee had been announced by the Rev. Joshua Dix, and some brief comments had been made by Mr. Wilson, the Chairman of the Fruit Committee, on the subjects brought before that body, the Rev. M. J. Berkeley proceeded with his remarks. Those who were at the last Tuesday meeting, he said, would recollect that attention was drawn to a species of *Peperomia* exhibited by Mr. Wilson Saunders, and which was supposed to be a new species. He (Mr. Berkeley) had the good fortune to meet at Kew, the other day, M. Casimir De Candolle, who had particularly studied the genus *Peperomia*, and he recognised the plant in question as being *Peperomia nummulariaefolia*. *Coburgia miniata*, from Major Trevor Clarke, was next noticed as a remarkably handsome but shy-flowering bulb. Its habit, Major Clarke observed in a note accompanying the specimen shown, is to produce a profusion of offsets, and the plan which he adopts to flower it is to grow it in small pots, to shift every spring, and, in order to remove the offsets as they appear, to keep the bulb three-parts out of the soil. If, on the contrary, increase is wanted, the bulbs are shifted into larger pots. The treatment in all other respects is the same as that of the *Hippeastrums*, to which the *Coburgias* are related. Mr. Berkeley then directed attention to *Lælia furfuracea*, from W. Wentworth Buller, Esq., a plant rarely seen in flower in this country, and perfectly distinct from *L. autumnalis*, with which it had been compared. Among cut flowers was an *Odontoglossum* from New Grenada, sent home by Mr. Weir, and which was considered to be new; there was likewise a spike of *Rhododendron Aucklandii*, and it was stated that the plant from which it was cut was 4 feet high, and was bearing fifteen of its magnificent spikes of white flowers. A hybrid *Rhododendron* from W. W. Buller, Esq., then came under notice. It was stated to have been obtained from *R. javanicum* and *R. jasmiflorum*, and to be almost if not quite the same as one that had been exhibited some time ago by Mr. Veitch (*Princess Helena*). It was a curious instance of a pink flower proceeding from an orange and a white. Of *Illicium religiosum* it was remarked that it would probably be hardy and produce its fragrant flowers on the south coast, like *Pittosporum tobira*, another Japanese plant, which at Margate formed large bushes, but in colder parts of the country required the protection of a greenhouse. *Bougainvillea splendens*, a distinct kind, more lively in colour than *spectabilis*, was the next subject to which attention was directed, and a letter was read from Mr. Daniels, stating that *Bougainvilleas* could now be had in bloom all the year round; for the flowering of *B. splendens* commenced, with the year and continued he knew not how long, that of *B. spectabilis* was prolonged from April to July, and *B. glabra* then commenced, and continued till the end of the year. *Nuttallia cerasiformis*, of which some flowering shoots came from the Society's garden, was then noticed; and Mr. Berkeley observed, that though not very attractive as seen at the meeting, yet when he saw it a fortnight ago at Chiswick, the bush had a very good appearance, and having the habit of the Ribes, and flowering abundantly at the present season, it deserved attention. After describing the structure of the flowers and fruit, Mr. Berkeley said that orders had been given to propagate the plant with the view to its distribution among the Fellows of the Society. Reference was next made to a cut spike of the beautiful *Rhododendron argenteum* which had been sent by Mr. Allis, of Gunton Park, near Norwich. Mr. Berkeley then exhibited a highly magnified drawing of the fungus which produces the formidable disease, called the muscadine, which preys on the silkworm; and as instances of other fungi existing in animal tissue, he cited the caterpillar fungus of New Zealand, which is sometimes brought to this country as a curiosity, and the fish moulds attacking living fish and rendering it very difficult to preserve them in health at the Zoological Gardens and other places. There were also fungi causing cutaneous disorders in man. His object in drawing attention to this subject was to make some remarks on the supposed connection between fungi and the rinderpest. Dr. Beale had, in a letter which appeared in the *Medical Times*, stated that in all cases of rinderpest entozoids were found to exist in the voluntary muscles, and in the involuntary muscles of the heart. Dr. Cobbold, however, determined that these bodies were not animal, but thought they were of the nature of Alge; but these are not known to exist in animals, though fungi are. In the same publication "A Provincial Physician" called attention to the fact that the fields were covered last autumn with an orange-coloured rust, but though he had examined the animals and found in them the spores, he did not meet with a single instance in which these had germinated. Mr. Berkeley expressed his opinion that it was perfectly possible that the bodies

discovered by Dr. Brale might be a form of some fungus, seeing that fungi were known to develop themselves in living animals; but as they were found not merely in animals which had died of the rinderpest, but in those which were healthy as well, he was not inclined to look upon them as the cause of the disease, though they might be a consequence.

Mr. Wilson Saunders remarked that these moulds seem to have little effect when the vitality of the animal is strong, but in cases of weakness and disease they might have a greater influence. With regard to *Coburgia minima*, he allowed the plant a little more pot room than Major Clarke, and, as a consequence, instead of one spike of flowers the bulb sent up two or three. He allowed more pot room, a season of rest, and then pushed the plant on when just beginning to move. As many of these bulbs form large, succulent, permanent roots, the earth in the pots should never be allowed to dry up so as to desiccate such roots; but, on the contrary, they ought to be preserved in a proper condition as regards moisture. In the case of bulbs with annual roots, as *Hyacinthus*, *Tulips*, &c., this did not much matter. The plan which he pursued with the *Coburgia* was to put it in a common greenhouse, there let it rest, and then push it on rapidly in a forcing-house. He would mention, that in Japan *Illicium religiosum* was planted near the temples, and there was, apparently, in that country a feeling for it similar to that which once existed for the Yew in our own. *Illicium religiosum* was the best species of the genus; its yellow flowers had a delicious perfume; and though it had been long known in this country it was not so much appreciated as it deserved.

Thirteen new Fellows were elected.

The exhibition last Saturday was much more extensive and varied than it was the week previously, and, notwithstanding the continued ungenial state of the weather, the contributions were of a gay and meritorious character. Several exhibitors made their appearance who have not been found at these meetings previously, and contested spiritedly, and in some cases successfully, the honours with those who have hitherto had it all to themselves. The schedule for the day consisted of prizes for the best collection of six miscellaneous plants in flower, and the first was taken by Mr. Beasley, gardener to Mrs. Wood, Acton, with six nicely bloomed plants, consisting chiefly of *Azaleas*, and a very nice specimen of *Chorozema Lawrenceanum* trained in the form of a balloon and full of bloom. Mr. Young, gardener to Mrs. Barelay, of Highgate, was second, with a very nice collection also; and Mr. Bartlett, of Hammer-smith, received a first-class certificate. In the class for collections of fruit there were very few exhibitors, the only award being made to a Queen Pine exhibited by Mr. George Ward, gardener to T. N. Miller, Esq., Bishop Stortford. There was a dish of Uvedale's St. Germain, from the west of England, sent as Chamonnet!

Besides the subjects exhibited for the prizes offered in the schedule, there were various others which required special attention, and first-class certificates were severally awarded to Mr. Young for collections of eleven *Polyanthus Narcissus*, sixteen *Hyacinths*, sixteen *Tulips*, twelve *Crocus*, and eight pots of *Lily of the Valley*. Mr. Bartlett was also awarded certificates for *Prunus sinensis alba plena*, cut flowers, and two specimen *Ferns*. Messrs. Cutbush, of Highgate, received extra prizes for a collection of forced flowers in bloom, and for forced bulbs. Messrs. Lucking, Brothers, also received a first-class certificate for their collection.

INTERNATIONAL HORTICULTURAL EXHIBITION AND BOTANICAL CONGRESS.

Among the many agencies which are being rapidly called into existence in furtherance of the interests of this great and important undertaking, a most valuable and successful one is that of local effort in the provinces, under the form of local committees or local secretaries. In the case of the former, a number of gentlemen have banded themselves together to work a given district; and in the latter case a gentleman has undertaken to do this individually. Up to the present time local committees have been formed, and are in active operation, at Sleaford, for Lincolnshire; Hon. Sec., Mr. D. Lumsden, the Gardens, Bloxholm Hall; Bristol, Hon. Sec., Mr. James Garaway, Durham Down Nursery; Oxford, Hon. Sec., Mr. W. H. Baxter, Curator of the Botanic Gardens; Warrington, Hon. Sec., Mr. W. Bishop, the Gardens, Dewsey Hall; Nottingham, Hon. Sec., Mr. E. J. Lowe, F.L.S., Highfield House; Derby, Hon. Sec., Mr. E. Coeling, Mile Ash Nurseries; Leamington, Hon. Sec., Mr. J. H. Hawley, Brunswick School; Hereford, Hon. Sec., Mr. N. Wynn, Midland Bank; Hertford, Hon. Sec., Mr. E. R. Francis, the Nurseries; and Doncaster, Hon. Sec., Mr. James Tindall, the Gardens, Spottborough Hall.

In Scotland these local committees are in active operation—viz., Glasgow and the West of Scotland, Hon. Sec., Mr. James Anderson, Meadow Bank, Uddingstone; Elgin and the North of Scotland, Hon. Sec., Mr. H. Rose, the Gardens, Floors Castle; and Kelso and the South of Scotland, Hon. Sec., Mr. W. Mien, Kelso.

In Ireland an influential local committee has been formed at Belfast; Hon. Sec., Mr. W. H. Ferguson, Curator of the Botanic Garden.

In the following places honorary local secretaries have already volunteered to act:—Manchester, Mr. John Shaw; Taunton, Mr. R. H. Poynter; Asect, Mr. J. Standish; Chester, Mr. Arthur Dickson (E. & A. Dickson & Sons); Bradford, Mr. W. Dean; Ipswich, Mr. T. Blair, the Gardens, Shrubland Park; Coventry, Mr. W. Miller, the Gardens, Combe Abbey; and Jersey, Mr. C. B. Saunders, Casarean Nurseries, St. Saviour's. Other committees are in course of formation throughout the country, and judging from the valuable aid the Executive Committee have already received from these sources, the most satisfactory results will ensue from their establishment.

Persons wishing to aid the movement should apply to the local secretaries in their several districts, from whom they can obtain the necessary papers, and also subscription forms, &c. The Executive Committee earnestly appeal to the horticultural community throughout the country for further help. The movement increases in magnitude and importance day by day, and with this comes a corresponding increase in the expenses to be incurred, despite the utmost vigilance in the financial department. From the gardeners have come a most liberal response, as the subscription list will testify, and it is hoped that a much larger number are yet to be enrolled as subscribers to the fund.

The Committee of the Botanical Congress to be held under the presidency of Professor A. De Candolle, now comprises the names of James Bateman, Professor Babington, W. Baxter, J. J. Bennett, Rev. M. J. Berkeley, Professor Bentley, W. Carruthers, Professor Daubeny, Charles Darwin, Dr. Hogg, W. Masters, J. McNab, A. G. More, Dr. Moore, T. Moore, J. Miers, W. Paul, Dr. Prior, J. G. Veitch, Dr. Welwitsch, Dr. Wright, James Yates, and others. Several papers have already been announced, and it is expected that a large number of foreign botanists and horticulturists will be present. Gentlemen intending to take part in the Congress should apply to Dr. Maxwell Masters, the Honorary Secretary, at the office of the Exhibition, 1, William Street, Lowndes Square, S.W.

VINE CULTURE.

Mr. WILLS has drawn inferences from my remarks that astonish me, and that were certainly neither intended nor conveyed. Referring to what I said about the difficulty of saying anything new on the subject of Vine-culture, and which it would appear constitutes the breach of courtesy referred to, he asks, "Is the cultivation of the Vine to stop at the point of perfection at present gained, whilst everything else is progressing?" Certainly not; but I do not think that horticulture, or any other science, is likely to be greatly advanced by an unnecessary repetition of facts already familiar to every one.

Secondly, Mr. Wills observes that I am wrong in assuming that he was attempting to introduce any new system of cultivation for the Vine. I should have thought that the observations just referred to, which he finds fault with first, would have been sufficient to exonerate me from such a charge. The idea of bestowing either the credit or the blame of such an attempt upon him never occurred to me.

Passing over his witticisms about painting Vines, &c., I will just observe that I know champion Grape-growers who use the spoke-brush for cleaning their Vines, and approve of it, and who, I have no doubt, will corroborate my statements should these remarks meet their eye; and I still maintain that a small amount of care is all that is necessary to prevent the buds of a well-ripened Vine shoot from being injured. I have often used the brush myself, without ever having my appetite set on edge for anything stronger than water.—T. S. W.

[We do not think Mr. Wills intended to make any offensive remark, and we can assure Mr. Wills that the writer of the above is the head gardener of a well-known domain. If they met by our fireside they would shake hands, and laugh heartily that any misconception had occurred. You shall not poke at one another any more, gentlemen.—Ems. J. or H.]

SKELETON LEAVES.—The leaves are boiled for two minutes, then transferred to a strong solution of permanganate of potash and gently heated. In an hour or two the laxer tissues may be easily removed by means of a brush. Sulphurous acid, or a solution of chloride of lime, may be used for bleaching

them. The stains of permanganate of potash upon the fingers are easily washed off by sulphuric acid.—H. F. CURCER, in *Chemical News*.

APHELEXIS CULTURE.

INQUIRIES having been made on this subject by a correspondent, the following, which is in answer to them, may be useful to other readers as well.

Presuming "A NOVICE" to be in possession of good, strong, compact, healthy plants in pots not more than 6 inches in diameter, though he may have larger plants, only it is necessary that they be well furnished or such as have been grown for specimens, he should, in the end of this month or beginning of April, give them a shift into pots a size larger. If, however, the plants are only such as never will make specimens (and I think this is the case), it would be better to put in cuttings in April, and grow them on. As "NOVICE" also wishes for information as to the mode of propagation, I will therefore commence with it.

The shoots eligible for insertion as cuttings are those about 3 inches long, strong, not showing flower, and with the base firm. This will be the case early in April. The shoots having been slipped off, trim the base with a sharp knife so as to take away any raggedness of the slip, and dress it for three-quarters of an inch upwards. The cuttings being prepared, they are to be inserted round the sides of a four-inch pot, nearly three parts filled with drainage, a sufficient thickness of sandy peat being placed over the drainage to leave room for three-quarters of an inch of silver sand at top. The cuttings are inserted so that their base may rest on the sand, and at the least possible distance above the layer of sandy peat. The pot thus prepared is to be placed inside one of larger size, so that both rims may be level, and the interval between the two pots may be filled with small gravel, or broken brick or crocks, putting sand on the top. Select a bell-glass which will fit on between the pots, give a gentle watering, put on the bell-glass, and place the cutting-pot in a temperature not more than 10° warmer than that of the house in which the plants grew from which the cuttings were taken. If the pots are plunged all the better. The sand should be just moist and no more. Give a little air at night only, by tilting the bell-glass a little, and shade from bright sun. The cuttings will be well rooted in six or eight weeks.

The next best time to take cuttings is towards the end of May, or from that time to the end of June, but the earlier the better. The cuttings should then be firm, but not fully ripe, and, instead of inserting them round the sides of a four-inch pot and setting it in a larger one, they may be potted singly in two-inch pots, draining efficiently to one-third the depth of the pot, placing over the drainage a layer of sandy peat, and over that from half to three-quarters of an inch of sand. A small hand-light, which need not be more than 3 feet long by 18 inches wide, may be placed on the table of the house in which the plants affording the cuttings are, and it should be filled with sawdust to within 3 inches of the glass. Cocoa-nut refuse, however, is a better plunging material, and moss answers well. The pots are to be plunged to the rim, and the light kept close by day and tilted a little at night to prevent damping, and, having a shady position, they will not require shading, unless the sun shine directly upon them, when a slight shade may be given. With careful watering the cuttings will root with certainty, if treated as above, and no undue excitement be given in the shape of extra heat, that of the house, from the advanced state of the cuttings, being ample. Instead of putting in the cuttings in small pots they may be inserted round the sides of a four or six-inch pot, and be placed under a hand-light within a cool house or pit. In either case they will be well rooted in six or eight weeks.

The cuttings when struck should be potted singly in three-inch pots, using a compost of turfy sandy peat two-thirds, and one-third pieces of charcoal, not larger than a pea, and broken crocks, the dust of both being removed; one-sixth of sand may be added. After potting place the pots in a frame near the glass, keeping close and shaded from bright sun, and the young plants will soon grow away freely. Now admit air and expose to the sun, but do it by degrees, and, to make them grow stocky or bushy, nip off the points of the shoots. They should be so exposed as to endure sun by the end of September. Early in October remove the plants to a light, dry, and airy shelf in a cool greenhouse where they can have air daily, but exclude frosty currents. Be careful not to over-water. In the first week of April pot them in 4½-inch pots, keep somewhat

close for ten days or a fortnight, and if growing freely take out the points of the shoots, but, if not, defer this and give them a six-inch pot in June, stopping a fortnight afterwards. After potting they should be placed in a cold frame, and when growing freely the lights should be tilted back and front. They are to be housed by the end of September, and have a similar position to that which they had in the previous year. The plants will now (April) be equal to those in six-inch pots purchased at a nursery, and whether raised or purchased the after-treatment will be the same.

To make specimen plants, pot into nine-inch pots early in April, and as the shoots grow peg or tie down the lowest so as to have the plants furnished to the rim of the pot. Give them another shift by the middle of June into 12-inch pots, stopping them soon afterwards, and never later than the early part of July, and keeping in a cold frame with plenty of air and light, protecting, however, from very bright sun by a very slight shade of some kind. Continue to peg or tie down the shoots so as to produce a compact evenly balanced head; and due care being taken of them in their winter quarters, they will make nice specimens for blooming in the following year.

In the following or first year of flowering the blooming shoots should be cut-in to within an inch or two of the old wood, and they will break strongly, in addition to which there will be some small stubby shoots that have not flowered; these will receive encouragement from the increased light and flow of sap, and they will for the most part ripen their wood well and flower in the following year. They are to be scrupulously preserved. When the shoots break afresh then is the time to repot, and, being in 12-inch pots, a shift into one 15 inches in diameter will be sufficient. In repotting turn the plant out carefully, and pick away the drainage and old soil so far as this can be done without injuring the fibres. Drain the pots extra well, and at this and the previous pottings, after shifting into six-inch pots, use for soil two-thirds turfy sandy peat, broken and torn with the hand, picking out the pieces of heath stem and root, and one-third charcoal in pieces from the size of a pea up to that of a walnut, and broken crocks of similar size sifted with a sieve having quarter-inch meshes to get rid of dust and the smaller particles. To this soil should be added one-sixth of silver sand, and let the whole be well mixed. Be careful not to bury the neck of the plant, but have it slightly elevated in the pot. Pot rather firmly, give a gentle watering, place in a cold frame, and keep close and shaded for a few days until the roots take hold of the fresh soil, which will be in about a fortnight. Then gradually expose to light, never shading at any time except from bright sun, and give air by tilting the lights back and front. Any strong long shoots may be stopped, but not after the middle of July, if they are expected to give flowering shoots for next year's bloom. The following year, if due regard be paid to pegging down, tying, and regulating the shoots, fair specimens will be the result. It will not now be necessary to repot after blooming and cutting-in; but, the drainage being good, it will suffice if some of the surface soil, and that around the sides of the pots, be removed, and its place supplied by fresh compost, giving weak applications of liquid manure when making fresh growths.

In subsequent years the plants may be fresh potted when required, though they will often continue in health for years if afforded a good annual top-dressing, and they may be either shifted into larger pots, or continued in the same size if a portion of the old soil is carefully removed. This should be done after the plants have been pruned back after blooming, and the shoots have grown a little. All potting should be done so that the roots may reach the sides of the pot before winter. The shoots should not be stopped after June, if the plants are to bloom in the following year. Never cut back into old wood, but leave enough of last year's wood to give new shoots. Tie down or peg the shoots, but do not use sticks, they spoil the effect of a good specimen. Judicious stopping and pegging down the shoots are all that is required to form specimens. After flowering keep the plants rather dry and cool for ten days or a fortnight, and, to hasten the production of new growths, keep rather close after cutting-in, and slightly syringe morning and evening to induce them to break freely and strongly. Some cut back immediately after flowering, keeping rather dry and cool for a fortnight, and then close and moist. I have tried both modes, and found them alike good.

Nothing is so hurtful to these plants as over-watering. The soil should be kept moist, but it must never become very dry nor very wet, for both extremes are equally destructive to the delicate fibres. Good drainage is of paramount importance.

Be very careful not to over-water in winter. After the flower-buds show, a gentle bedewing of the plants overhead early in the morning and afternoon will do good, but this should be done on bright days only, and weak liquid manure may also be given; it may be made from cowdung one year old, one peck to twenty gallons of water, a quart of soot being added.

In summer a cold pit is the best situation, and in winter a position in a dry and airy house with a temperature of from 40 to 45 from fire heat, with a rise of 10° or 15° from sun heat. They must have a position near the glass, and the light either from overhead or sideways should not be intercepted by other plants. They cannot have too much air, but cold frosty currents are to be excluded. Air, when the external atmosphere is frosty, may be given at the back of the house. A slight shade when making new growths is desirable, but in autumn, in order to have the wood well ripened, they require all the light possible.—G. ABBEY.

POINSETTIA PULCHERRIMA CULTURE.

I HAVE been much pleased to see the culture of the Poinsettia so ably discussed by your correspondent Mr. Lane, at page 100, and, so far as the dwarfing of the plants is concerned, I quite agree with him, but I question very much whether, by the means he describes, that fine glossy foliage can be secured which adds so much to their beauty. I am, besides, convinced that to procure large bracts the plants cannot be grown too strong, and this can only be secured by plenty of heat and humidity and the use of stimulants. As I before stated, it is essential that the plants should be placed in a situation where they will be well exposed to the light, and as close to the glass as possible; growing them strong is very different from drawing them upwards by keeping them in a shady position. The more vigorous the plants are the longer will be their continuance in bloom.

My flower-heads began to open in the first week in November, and I have now (February 12th), some in good condition on the same plants. I will here correct a statement which I made with regard to the measurement of my flower-heads. I said that they were from 14 to 16 inches across, but I am sorry that I made this statement by guess, for in a few days after I wrote a friend came to see them, and he measured one which was 17 inches across, and in another fortnight the same head was found to be 20 inches in diameter, and the largest of all fully 21 inches. The latter is hanging in the stove now. My house, perhaps, is peculiarly adapted for keeping the flowers. It is a low span-roofed structure running east and west, with a top ventilator opening from end to end, and I constantly keep a little air on night and day, so as to allow of the atmosphere continually circulating among the plants. I had each brought down and tied to some cross bars that traverse the house for support, each head being turned to face one way; the effect on entering the house was extremely fine.

For dinner-table decoration the Poinsettia has no rival; the way in which it is here managed for this purpose is as follows:—We have a round tin tray with a block in the centre for the feet of the epergne, and around this block is packed a quantity of moss so as to fill the tray, some of the greenest flakes being selected for the outside. This being done, and the whole made secure, the flower-heads are cut, and the ends of the portions of shoot attached are placed in the moss. The Poinsettias are interspersed with white Camellias, and a few delicate Fern fronds to prevent a formal appearance. The effect by candlelight of this arrangement is magnificent.

Another great advantage of the Poinsettia is that there is no flower to equal it in respect to the length of time which it will last in water if regularly attended to. By applying tepid water every day the heads will last fresh for a month, and I have even kept them quite fresh longer than that. It is strange that no attempt at improvement has been made by crossing the white and scarlet varieties. I am only sorry that the means at my command being limited, I have not scope for many of our neglected stove plants. I should read with much interest the practice of others who may have been successful in the cultivation of the Poinsettia.—CHARLES EDWARD S. Bristol.

PERIODS OF DROUGHT AT CARDINGTON.

It may be interesting to some of the readers of this Journal to know the periods of dry weather of fourteen days and upwards since 1845, in one of the midland counties, where the

monthly fall of rain is under 2 inches. I will also state the number of days in each year on which no rain fell, dates included.

From June 21th, 1846	to June 22nd, 1846	being 14 days.
.. Sept. 7th, 1846	to Sept. 22nd, 1846	.. 16 "
.. March 8th, 1847	to March 22nd, 1847	.. 15 "
.. Sept. 23rd, 1847	to October 6th, 1847	.. 14 "
.. April 30th, 1848	to May 18th, 1848	.. 19 "
.. July 4th, 1849	to July 17th, 1849	.. 14 "
.. Feb. 17th, 1850	to March 3rd, 1850	.. 15 "
.. March 5th, 1850	to March 22nd, 1850	.. 18 "
.. Sept. 5th, 1850	to Sept. 19th, 1850	.. 15 "
.. June 17th, 1851	to July 1st, 1851	.. 15 "
.. Sept. 6th, 1851	to Sept. 23rd, 1851	.. 18 "
.. March 3rd, 1852	to March 20th, 1852	.. 27 "
.. April 1st, 1852	to April 17th, 1852	.. 17 "
.. June 30th, 1852	to July 13th, 1852	.. 14 "
.. May 15th, 1853	to May 28th, 1853	.. 14 "
.. July 30th, 1853	to August 16th, 1853	.. 18 "
.. Feb. 24th, 1854	to March 10th, 1854	.. 15 "
.. March 28th, 1854	to April 20th, 1854	.. 24 "
.. August 27th, 1854	to Sept. 12th, 1854	.. 19 "
.. April 13th, 1855	to May 3rd, 1855	.. 21 "
.. Feb. 21st, 1856	to March 16th, 1856	.. 25 "
.. Sept. 8th, 1856	to Sept. 21st, 1856	.. 14 "
.. Aug. 17th, 1857	to Sept. 1st, 1857	.. 16 "
.. Dec. 23rd, 1857	to January 7th, 1858	.. 16 "
.. March 18th, 1858	to March 31st, 1858	.. 14 "
.. June 19th, 1858	to July 4th, 1858	.. 16 "
.. Nov. 10th, 1858	to November 25th, 1858	.. 16 "
.. June 5th, 1859	to June 19th, 1859	.. 15 "
.. July 5th, 1859	to July 18th, 1859	.. 14 "
.. Nov. 10th, 1859	to Nov. 26th, 1859	.. 17 "
.. October 27th, 1860	to November 10th, 1860	.. 15 "
.. July 21st, 1862	to August 6th, 1862	.. 17 "
.. Feb. 5th, 1863	to February 18th, 1863	.. 14 "
.. March 21st, 1863	to April 4th, 1863	.. 15 "
.. July 4th, 1863	to July 18th, 1863	.. 15 "
.. April 18th, 1864	to May 1st, 1864	.. 14 "
.. Sept. 21th, 1864	to October 19th, 1864	.. 29 "
.. April 20th, 1865	to May 4th, 1865	.. 15 "
.. June 4th, 1865	to June 23th, 1865	.. 20 "
.. August 30th, 1865	to September 20th, 1865	.. 22 "
.. Sept. 22nd, 1865	to October 8th, 1865	.. 17 "

Only seven times during twenty years have the number of dry days exceeded twenty at one time, and two of these times were in 1865.

The following shows the number of days in each year on which no rain fell, from 1846 to 1865, inclusive:—

Year.	Days.	Year.	Days.	Year.	Days.
1846	201	1853	194	1860	169
1847	230	1854	230	1861	204
1848	169	1855	225	1862	184
1849	193	1856	214	1863	234
1850	223	1857	220	1864	250
1851	217	1858	240	1865	252
1852	204	1859	219		

From these figures it will be seen that it was in 1864 that there were the greatest number of days on which no rain fell; also in that year the least fall of rain took place, being 5.564 inches below the average of twenty years.

Cardington is situated about three miles from Bedford, one mile from the river Ouse, 12 feet above the level of the river, and 100 feet above the sea level. The weather is generally very dry in summer, and very damp in winter.—JOHN McLAREN, Gardener to S. C. Whitbread, Esq.

WEATHER WISDOM.

(Continued from page 108.)

The chief cause which tends to throw discredit on a barometer is the introduction on the scale of the words fair, rain, stormy, &c. It is not my present intention to consider why these words were introduced, but rather to point out the reasons why they ought to be disregarded by those whose object it is to study the barometer, and by its fluctuations to anticipate probable weather. I may here observe that in instruments made for the National Lifeboat Institution the words I have mentioned do not occur, as it was considered they did more harm than good. In their place, however, are inserted short practical hints, informing the observer on what occasions the barometer rises and falls, and what future weather may be expected from such variations, &c.

In the first place, the height at which a barometer is fixed above sea level is not always taken into account by observers. It has been explained on a former occasion (page 27), that the mercury does not stand so high when a barometer is taken to the summit as it does when observed at the foot of a hill, and, therefore, the inexperienced are placed in the following dilemma:—A man observes his glass (one I will suppose by a good maker), and he sees the mercury in the tube is level with the

word change on the scale (29.50). He then visits a friend who lives in a house situated at a much higher elevation than his own. Passing through the hall he sees a barometer reading considerably lower than his did. Perhaps he calls the attention of his friend to this fact; the person thus appealed to says his instrument is right, and accordingly the other thinks to himself, "Both cannot be right;" and yet both are right. What is change (29.50) at sea-level will become rain (29.00) about 500 feet higher than sea-level, because one-tenth of an inch must always be added to the readings of a barometer for every 100 feet the instrument is placed above sea-level. Your readers may say, "We do not know the height we are situated above sea-level, and how can we find out?" The answer to such an inquiry is to be found on the ordnance map, where the height at which different localities are situated above the sea-level is clearly marked out and defined.

From what has been just remarked it will be at once perceived that there is a disadvantage in the use of the words fair, change, &c. Why should an observer who lives some 100 feet above sea-level be obliged to remember that on his glass change does not mean change, but fair? Now, in barometers without these words, although of course an observer at a lower station would find a difference when comparing the readings of his instrument with those taken by one at a higher level, there would not be that discrepancy in the words just alluded to, and I apprehend that a person who has in his possession a barometer on which these words are omitted pays more attention to the rise and fall of the mercury, and makes his own deductions more accurately, than others who are misled by the words previously referred to.

Assuming in the next place that an observer knows the height at which he is situated above sea-level, and therefore in his readings of the barometer makes the proper allowance for such elevation, why is it that the words fair, &c., are liable to mislead him, and to become a stumbling block to his knowledge of weather? The reason is as follows:—A barometer is never to be judged by its readings at the moment of observation, when any one wishes to know the probable weather which may be expected at that time. The instrument, as a rule, is always beforehand, and does not tell present weather. Weather wisdom is attained by looking at the previous movements of the column, and accordingly if the mercury has risen to fair, but the rise has been very sudden, or the barometer has oscillated to or from that point for the last few days, heavy and unsettled weather may be expected. However, the bad weather will not be so long in duration with a high barometer as it would have been had the glass been very low for some days. On the other hand, the column steadily rising towards fair does show settled and fine weather, and in that case the words fair and set fair on the scale of an instrument at sea-level, or reduced by correction to that level, are really right. I would ask your readers, Is it not better to pay no attention to words which have a double signification, and do most undoubtedly mislead the inexperienced? Doubtless many persons know of instances where an umbrella is never taken out of a stand when the glass is above change, and what is the result?—very often a severe wetting; the barometer is blamed, but who, I ask, is really to blame? Again, has the science of weather taken deep root in a family where such remarks as the following are heard?—"My barometer is rising fast, and we shall have fine weather," when the present state of weather wisdom suggests the very opposite—viz., unsettled and changeable weather.—X., Surrey.

ENTOMOLOGICAL SOCIETY'S MEETINGS.

THE Anniversary Meeting of this Society was held on the 22nd of January, F. P. Pascoe, Esq., F.L.S., President, in the chair, when the appointment of the Council and Officers for the ensuing year took place, Sir John Lubbock, Bart., F.R.S., being elected President; Mr. Pascoe's term of office having expired. The other officers were re-elected.

The President announced that the Council's offer of prizes to be awarded to the authors of essays on economic Entomology, had produced three competitors, and that the Council had awarded one of the prizes, of the value of five guineas, for an Essay on Ailanthi culture, the author of which proved to be Dr. Wallace, of Colchester, and in which an elaborate account was given, from personal experience, of the Ailanthus Silk Moth (*Saturnia Cynthia*), the practicability of the cultivation of which, as well as of that of the Ailanthus tree itself in the most unpromising situations, was fully demonstrated. The President, before leaving the chair, read an address on the progress of

entomology during the past year, which, as well as Dr. Wallace's memoir, was ordered to be printed for distribution among the members.

The meeting held on the 5th of February was presided over by Sir John Lubbock, the newly-elected President, who returned thanks for his election, and nominated Messrs. Wilson Saunders, Pascoe, and Westwood, Vice-Presidents for the ensuing year. Amongst the numerous donations to the Society's library, were the publications of the Entomological Societies of New South Wales (Part 4), and of Stettin. The prize awarded by the Council to Dr. Wallace, for his memoir on Ailanthi culture, was presented to that gentleman, who, in returning thanks, stated that the cultivation both of the Ailanthus tree and of the Silk Moth itself, appeared to be even more flourishing in this country than in France, where it has now become an object of much importance. The President announced that the Council had determined to renew their offer of two prizes of five guineas each, for memoirs of sufficient merit, and drawn up from personal observation, on the anatomy, economy, or habits of any insect, or group of insects, especially serviceable or obnoxious to mankind. The essays to be sent to the Secretary on or before the 30th of November, 1866. M. Guerin Meneville, of Paris; and M. Bohemann, of Stockholm, were elected honorary members of the Society.

Mr. McLachlan exhibited, on behalf of Mr. Dorville, *Sterria sacchararia*, captured near Exeter, and a number of remarkable varieties of British species of Butterflies and Moths, including a gigantic *Cynthia Cardui*, or Painted-lady Butterfly, *Hipparchia Fithonius*, with an additional ocellus, *Agrotis Segetum*, nearly black, &c.

Mr. S. Stevens exhibited the male of *Papilio Semperi*, remarkable as being the only known Lepidopterous insect with a brilliant scarlet body and jet black wings. It is a native of Mindanao in the Philippine Islands.

Professor Westwood exhibited a pair of the Dog-tick, which he had kept without food in a glass tube for twelve months, having been a portion of the specimens presented by Major Cox to the Society in February, 1865; shortly afterwards a number of young ones were observed in the tube, which, however, soon died, but the tube was now again thronged with young in the hexapod state, but the female was no longer alive. He also exhibited the interesting larva of *Tipula replicata*, found in damp moss by Mr. Edwin Brown, of Burton, remarkable for the strong analogy which it exhibits in the long branchial filaments upon the sides and back of its body, with the aquatic larvae of the Neuropterous genus *Sialis*, and the Lepidopterous genus *Hydrocampa*.

Mr. Wilson Saunders exhibited a very extensive and beautiful series of Butterflies belonging to the genus *Heliconia*, which had been captured in a single locality in Cayenne, and which varied to so great a degree, both in their markings and colours, as to have been regarded as a number of distinct species, but which Mr. Saunders considered were only varieties of a single species, *Heliconia Melpomene*. This exhibition led to an extensive discussion on the geographical range of the species, and on the effects of situation on the modification of the specific characters of the insect, in which Mr. Bates stated that he had taken nearly all these varieties on the Amazon, and that he was induced to consider, that in certain localities the species appeared to be constant in its colours and markings, but that in the hilly districts of Guiana the species was subject to endless variation, whilst elsewhere it appeared to resolve itself into three distinct variations, which had been named *H. Melpomene*, *Helixiope*, and *Vesta*. He had succeeded in breeding *H. Erato*, and had found its caterpillars to be gregarious.

The President exhibited magnified coloured drawings of two curious larvae of unknown forms.

Mr. F. Smith communicated a note from Mr. Henry Doubleday, in which the doubts expressed by the former at a previous meeting, as to the origin of the tapping noise often heard in old houses, alleged to be made by the Death Watch, *Anobium striatum*, were completely disproved, Mr. Doubleday having repeatedly observed that insect in the act of making the noise in question, by striking its head against the surface upon which it was standing. He had kept the insect in confinement and could make it reply by tapping any hard material with a pencil.

Mr. Wallace mentioned, that in repairing an old church at Colchester, the Oak beams on the south side of the roof were chiefly attacked by the Anobium.

Mr. Stanton announced the death of Senator Van Hyden, one of the oldest and best entomologists of Germany, and the arrival of Mr. Wollaston, on an entomological excursion to the Cape de Verd Islands.

Memoirs were read by Mr. Bates on new Phytophagous Beetles; and by Mr. Hewitson on new species of Hesperidan Butterflies.

NOTES ON THE SPECIES OF HELLEBORUS.

(Continued from page 145.)

HELLEBORUS OLYMPICUS, Lindley (The Olympic Hellebore).—Syn. *H. guttatus*, of gardens; *H. colchicus*, of gardens; *H. olympicus albus*, of gardens; *H. abehasicus*, Fischer. The radical leaves of this species are palmate, with the segments oblong-linear and toothed on the margins, except near the base, which is entire. The floral leaves are large, stalkless,

and sharply serrated on the upper half. The flowers are cup-shaped, greenish-white, with the sepals bluntly egg-shaped; persistent, and produced on forked flower-stems a foot high, and which, as well as the leafstalks, are beautifully mottled with reddish brown spots.

This kind is a native of the Bithynian Olympus, and flowers from February to April.

Dr. Lindley, who first described this species, gives the following as its distinguishing characters from the other species of the genus—viz., "From *Helleborus orientalis* it differs in having palmate not pedate radical leaves, which are less acute and more finely toothed; in its two-flowered stems, and in its smaller flowers, which are pale green and not coloured like flowers. From *Helleborus niger* it differs in its leafy scape being much longer than the leaves, which are palmate and not pedate; in the form of its leaflets, which are serrated almost to the base, and want the almost rhombic form of that species. From *Helleborus odorus* it differs in its white and earlier flowers, thinner and smaller leaves, and an entire want of the coarse prominent ribs that stiffen the foliage of that plant. From *Helleborus purpurascens* it differs in its larger floral leaves and finely toothed leaves; from *Helleborus atrorubens*, to which it is nearest, in its much larger pallid green flowers, rounder sepals, and broader, palmate, not trifid, floral leaves; the leaves, moreover, are much more leathery than in that species."

HELLEBORUS ODORUS, Waldstein (The Sweet-scented Hellebore).—Syn. *H. odoratus, of gardens*. The root-leaves of this species are palmate, pubescent on the under surface when young, with the segments oblong, quite entire at the base, but serrated towards the apex. The flower-stems are about a foot high, forked near the top, and bearing large, solitary, sweet-scented, greenish-white flowers, the sepals of which are ovate-oblong and permanent. This kind is a native of Hungary, and flowers in February and March.

HELLEBORUS PURPURASCENS, Waldstein (The Purplish-flowered Hellebore).—Syn. *H. purpureus, of gardens*. This species has the root-leaves palmate, with the segments wedge-shaped at the base, pubescent on the under side, and from three to five lobed at the apex. The floral leaves are nearly stalkless, and the stems two-flowered, with the sepals roundish, permanent, and of a purplish colour when young.

This kind grows about a foot high, and flowers in March and April. It is a native of Hungary, Podolia, and Volhynia.

HELLEBORUS ATRORUBENS, Waldstein (The Dark-purple Hellebore).—The radical leaves of this fine species are very smooth, pedate, shining, and paler underneath, with the stem-leaves nearly sessile and palmate. The flower-stems are somewhat angular, bifidly-branched, and about 18 inches high. Flowers, when young, dark purple, particularly towards the edges of the sepals, which are roundish and permanent.

This species is found plentifully in woods and bushy places in Hungary. There it flowers in February and March.

HELLEBORUS MULTIFIDUS, Visiani (The Multifid-leaved Hellebore).—Syn. *H. Bocconi, Tenore*. The root-leaves of this kind have long footstalks, are very large, leathery, smooth, and pedate-parted, with the segments narrow, lanceolate, taper-pointed, sharply-serrated, very veiny, dichotomously-lobed, and wedged-shaped at the base. The flower-stems are tall, angular, bifid, and with broad, ovate, greenish floral leaves, palmate-parted, and almost sessile. Flowers large, cup-shaped, with broad ovate sepals, of a light greenish colour.

This species, according to Professor Visiani, resembles *Helleborus dametorum*, but is larger in size and flowers more freely.

It is a native of the Apennines of Etruria and Dalmatia, where it grows from 1½ to 2 feet high, and flowers from February to April.

HELLEBORUS DUMETORUM, Waldstein (The Thicket Hellebore).—Syn. *H. laxus, of gardens*. The radical or root-leaves of the Thicket Hellebore are pedate, very smooth, and spreading, while the stem-leaves are almost sessile and palmate. The flower-stems grow about a foot high, are round, bifidly-branched, and bear large, cup-shaped, solitary flowers, with round, greenish-white sepals.

This species is a native of Hungary, and flowers in March and April.

HELLEBORUS VIRIDIS, Linnaeus (The Green-flowered Hellebore).—The root-leaves of the Green-flowered Hellebore are very smooth, pedate, and on long footstalks, while the stem ones are almost stalkless and palmate. The flower-stems are 18 inches high, forked, and bear solitary cup-shaped flowers

on the ends of the peduncles. The sepals are roundish ovate, and bright green.

This kind is a native of many parts of Europe, and is found wild in woods and thickets, in chalky soil, in England, where it flowers in April and May.

The roots of the Green Hellebore are frequently substituted for those of the Black Hellebore of the East, and are said to possess nearly the same medicinal qualities.

HELLEBORUS LIVIDUS, Atton (The Livid or Corsican Hellebore).—Syn. *H. argutifolius, Visiani*; *H. trifolius, Linnaeus*; *H. corsicus, of gardens*; *H. trifoliatius, of gardens*. This is a very singular evergreen species, with a many-flowered leafy stem about a foot high. The leaves are ternate, leathery, very smooth, glaucous beneath, and pale green above; the segments of the leaf are ovate-lanceolate, irregularly incised, with large, wide, sharp-pointed serratures along the margins. The flowers are cup-shaped, light green, and a little larger than those of the Fetid Hellebore.

The Livid-flowered Hellebore is a native of Corsica and the Balearic Islands, particularly of Majorca, and flowers from January to May.

HELLEBORUS FETIDUS, Linnaeus (The Bear's-foot Hellebore).—This is a well-known evergreen herbaceous plant, with very smooth, deep-green leaves, having oblong-linear segments, and a many-flowered leafy stem from 1 to 2 feet high.

The Fetid Hellebore is found wild in many parts of Europe, and is a native of England, where it is common in shady places in the chalky counties. The whole plant is fetid, acrid, and a violent cathartic, especially the green leaves; but these, when dried, are sometimes given as a domestic medicine to destroy worms. It flowers in March and April, and produces a very pleasing effect in shady places during the winter months.—GEORGE GORDON, A.L.S.

GAS LIGHTING A CONSERVATORY.

I HAVE lately seen some inquiries in the Journal as to the best means of preserving plants in conservatories from the effects of gas; but none of your correspondents mentions anything like the following, which I saw fitted up and frequently used for two years. I send you a description of it, in the hope that it may be of use to some who are thinking of lighting their conservatories with gas.

On the top of the glass was a copper plate, to which was attached a funnel, passing through the rafter to the outside, for the escape of the heated air. A tube at each side of the funnel was brought in and entered at the bottom of the glass, to supply fresh air to the flame. The small door at the bottom, to allow of lighting the gas, had an indian-rubber flange, which made the whole perfectly air-tight. I may mention that the gas-pipe was run up under the rafter, where it entered one of the cold-air tubes, and was brought down it into the glass. The tubes were bronzed, and the outer two twisted in imitation of a rope. The whole had a very ornamental appearance, and, as it was air-tight, of course had no effect whatever on the plants.—A. A.

a. Glass.
b b. Air-tubes.
c. Funnel.
d. Door.
e. Rafter.

WORK FOR THE WEEK.

KITCHEN GARDEN.

A DISTINGUISHING feature in this department is its uniformity—straight lines and angles meet the eye in every direction; and whatever may be said in favour of a departure from this rule in the disposition of pleasure grounds, we cannot deny that straight lines are preferable for the kitchen garden. Straight walks, with the edgings neatly kept, seed-beds of a uniform width, with the seeds drilled in at equal distances, the disposition of plants in rows, trees all trained with the greatest exactness, together with continual surface-stirring, and the consequent absence of unsightly weeds, are amongst the dis-

tinguishing characteristics of a well-kept kitchen garden. Attend to the sowing of main crops as directed in previous calendars, and keep up successional sowings of vegetables to come in, according to the state of the weather and the probable demand. *Asparagus*, if not done in the autumn, dress the beds with light decomposed manure, and fork them lightly over, taking care not to injure the crowns. Many persons apply salt at this time in the proportion of about a pound to the square yard; but it is more advisable to defer this until the cutting is over, and the plants are in a growing state, because then they are in the best condition to receive the benefit of the application, and the crowns are greatly strengthened for the following season. The beds intended for new plantations to be frequently turned, to be in readiness for planting the young roots as soon as they have shot 2 or 3 inches. *Artichokes* (*Globe*), should now be dressed, superfluous shoots removed, and fresh plantations made if required; as this is generally a permanent crop, the ground should be well prepared by deep trenching and a plentiful application of rich manure. *Cucumbers*, keep the lights free from dirt, wash them inside and out if there are lights to shift them, keep the heat of the beds from 75° to 80°, but particularly guard against a violent bottom heat. *Cauliflowers*, give due attention to the plants under hand-lights, by surface-stirring and giving air on all suitable occasions, tilt the glasses on the side away from the wind in cold searching weather, and remove them entirely on the first occurrence of genial showers; do not let plants in frames, or the young seedlings which are now pricked out, suffer from exposure to the biting east and north-east winds so prevalent at this season of the year. *Parsley*, a good sowing should now be made; clean and loosen the soil between the rows sown last season. *Potatoes*, the main early crops should be put in as soon as the weather will permit. *Sea-kale*, cover up a succession. Fermenting materials may soon be dispensed with for this purpose, as it will merely require to be covered for the purpose of blanching.

FRUIT GARDEN.

With respect to the covering of wall fruit trees, we would advise canvas curtains, so fixed as to be removable at pleasure; their expense is generally the great drawback, but against this should be placed a crop, or rather many crops, of fruit, as the canvas will, with care, last for years. They will also serve to protect Plums, Cherries, &c., and retard ripening, which is a matter of great importance where families do not visit their country seats till the autumn. Whatever covering may be used for protecting the blossom of wall trees, the ends should be secured so as to prevent a current of cold air passing between the wall and protecting material, as, in this case, the destruction of the bloom is almost certain. If it is necessary to dig among fruit trees, let it be done as shallow as possible, so as not to injure the roots. Weed Strawberry plants before the weeds begin to grow much. Look over the fruit in the fruit-room; if it is damp, open the windows a few hours on a fine day.

FLOWER GARDEN.

If the plants with which the beds in the flower garden are to be planted this season are not decided upon, the sooner this is done the better. Proceed with the planting out of biennials of all kinds, and prepare a piece of ground for a sowing of *Anemone coronaria*, *hortensis*, and *vitifolia*. *Anemones* delight in a strong rich soil, and a rather shady situation in summer. Sow the seed, after it has been well rubbed in sand, in shallow drills 9 inches apart, and cover with rich soil. A sowing of Ten-week Stocks to be made on a warm sunny border, cover with litter or mats at night until the seeds begin to vegetate. Sow likewise a general assortment of hardy annuals, such as *Clarkias*, *Collinsias*, *Leptosiphons*, *Nemophilas*, &c. Herbaceous borders, if not dressed over in the autumn, must be attended to immediately, and either fresh compost or manure must be added to the plants that are weakly.

GREENHOUSE AND CONSERVATORY.

Potting will now be a matter of daily occurrence, and on the mode in which this is performed will depend the future success of the plant. We need say little here about the propriety of using fibrous soil or about thorough drainage, these matters are tolerably well known; but a few words to the amateur as to the best mode of watering newly potted plants in general may be acceptable. Let it be a rule, then, never to water a fresh-potted plant. The soil for potting should be neither wet nor dry, one is as great an evil as the other; it should of the two incline to dryness, and should be pressed tolerably firm.

The watering at first should not be performed in order to settle the soil—this means shutting out the atmosphere, but merely with the intention of preventing the soil from becoming any drier. Hard balls should be soaked in water a day previous to shifting. The families of *Camellia*, *Acacia*, *Cytisus*, *Rhododendron*, *Eutaxia*, *Citrus*, *Epaeris*, *Correa*, *Azalea*, and last but not least the *Rose*, will be a blaze of beauty where plant-growing is well attended to. They will now require abundance of water. Dispense with fire heat in the conservatory as much as possible, and admit air on all favourable occasions. On still nights the house may be damped and the syringe used; and as the plants exhibit vigour atmospheric moisture may be increased generally. In the greenhouse continue the necessary operations of shifting, training, and the general arrangement of the plants. The employment of soil containing a considerable portion of decomposed vegetable fibre must obviously be suitable to dwarf-growing plants, the natural habit of which leads us to the supposition that such soil existing on the surface must form, from its being readily available to them, their congenial and natural food.

STOVE.

Attend to the disrooting and pruning back of *Justicias*, *Vincas*, *Clerodendrons*, *Eranthemums*, *Geissomerias*, *Plumbagos*, *Poinsettias*, *Erythrinus*, &c., at least those exhausted by flowering, or a few for early work. Orchids are now swelling fast; and many of the blocks and baskets of *Stanhopeas*, *Gongoras*, *Dendrobiums*, &c., will require to be syringed about twice a-week. Let this be done early on sunny mornings, and give air freely for a couple of hours, for fear of moisture lodging amongst the buds. Terrestrial Orchids in general will do better in loamy turf and leaf mould (not too much decayed), blended with the lumps of peat. Renew moss on blocks forthwith.

PITS AND FRAMES.

Here the work needs no pointing out. The means of providing room after the plants are potted is the greatest difficulty in most gardens. Calico dressed with Whitney's composition at the cost of 5d. per yard will answer as a protective material after plants are first potted off. Choice annuals, such as *Brachycome iberidifolia*, *Viscaria oculata*, *Mesembryanthemum tricolor*, *Portulacas*, *Clintonias*, and the like, should always be potted off as soon as they are sufficiently large to handle, and afterwards be placed in a warm moist atmosphere, with plenty of air in mild weather, until they are properly established. Sow in a brisk heat *Martynia fragrans* and *diandra*, the different varieties of *Thunbergias* and *Ipomaeas*, *Convolvulus major* and minor, and, where they are admired, the common yellow and other *Lupines*.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

As yet little has been done in the open ground except some trenching. Will plant out and sow *Peas* and *Beans* the first favourable opportunity. Planted a row of Tom Thumb Pea—nice stubby plants—in front of the latest orchard-house; will also plant a row of more forward ones, and some of *Dillistone's* Early in the earlier orchard-house, and we set a row in 10-inch pots on the border in front of the wall of that house, removing them from the Peach-house where they stood on a shelf extemporised by placing three iron rods, covered with moss, on the top of pots to bring them near enough the glass. The Peas were showing the first tendency to draw, and the moving of them will keep them stubby, and bring them, with more light, sooner into full bloom. This shelf was again filled with Dwarf Kidney Beans, transferred without breaking the ball, from 40-sized pots into 16's, and the soil previously mellowed by standing two or three days in a warm place. It is hardly right to say that the balls in these small pots were untouched, as the fingers were inserted a little along the outside to disentangle the fibres. The only advantage of such transplanting is that room is husbanded, but at the expense of labour; and in all such transplanting and repotting at this season much of future success and freedom from insects depend on not chilling the young roots with cold soil.

With rats and mice there has been great difficulty in keeping Peas and Beans, even under protection, and in these cold, frosty mornings the garden was so like a pheasantry that not a Pea would have been left if not securely netted. When planted out 3 or 4 inches in height and staked at once, even pheasants and partridges seldom meddle much with them, and after the

first crops go on they do not meddle much with the later crops. Brussels Sprouts and Broccoli have been considerably pecked by pheasants within the last few weeks. Where *gam* is made the principal object near gardens, there will be no fair chance for the garden unless pretty well netted. Thousands and thousands of small birds are encouraged by the food put down for the pheasants, and these, with mice and rats encouraged by the same means, will be sure to visit the garden whenever they are on short commons. With the exception of the matchless farm-stealing at Luton Ho, there is scarcely the attempt in this neighbourhood to keep stacks of grain from the depredations of vermin. There is something very soothing and refreshing to the spirit in noticing the pretty spring flowers as they peep out in the hedge-banks round corn fields; but the horrid scent from a corn stack too often scatters to the winds everything approaching poetry and sentimentality. Perdid as such feelings may be by the mere utilitarian, life itself would be a hard, miserable, dried-up affair without a dash of the imaginative and the poetical. Without the sentimental, the natural, and the beautiful connected with gardening, who would undergo the hard work with head and hands, and the continuous care, and yet continuous disappointments and want of appreciation, which the gardener often experiences? Within the last three months we have had a number of letters urging us to take up the game question as connected with gardening; but what would be the use of it? Why do those who suffer most not tell where the shoe pinches? It is a matter entirely for private statement or individual representation. When a gentleman sees his vegetables stripped, and his early Peas cleared from end to end of a row by game, it requires no great amount of discernment to see that what the game eat and destroy cannot yield a produce to appear at his table. The complaint of the gardener is that no allowance is made for such depredators, and that he is permitted to purchase neither wire nor other netting to keep them away. This we fear in many cases is too true; but in time the evil will bring its own remedy. The whole subject is more fitted for private expostulation than for public comment; but we hesitate not to say this much, that when a garden is turned into a game preserve it will be rather difficult to make it a preserve for anything else.

Brought home some tree leaves, which will enable us to plant a lot of Potatoes in an earth-pit, and sow Radishes, &c., between the rows. Radishes from the Carrot-bed have been good for some time past. Will clear out an Asparagus-bed under glass, and sow with Turnips and White Turnip-rooted Radishes, as the latter when young come in well for cutting up. Potatoes in pots are coming on nicely, which is so far good, as we are behind with those in beds. Took up a lot of Jerusalem Artichokes. For soups they may remain for years on the same ground, but for a dish they are best planted every year, the same as Potatoes.

Sea-kale.—Turned out the Sea-kale that had been forced, into an open shed, packed it with dry soil, and sprinkled a little litter over the crowns, and will plant again when the crowns are moving, and are thus hardened off. Pieces of roots, obtained from trenching the ground whence the roots to be forced were taken, were cut into pieces from 6 inches in length, and packed in a similar way, and they plant best when the buds are beginning to appear like small pin-heads at the upper end, which is left just above the surface. These, though not our usual plan, we will replant in the same ground from which they were taken, after trenching, enriching with hotbed dung, and making it light with burnt clay and rubbish. Took up some more Sea-kale, and put it in the Mushroom-house; this, we hope, will be about the last if the weather become mild. Covered some rows in the open ground with pots, and over them a little litter, just to keep the pots from frost, and in a week or two will cover more. Common six or eight-inch pots will do for this purpose as, for a number of years, we have preferred growing the plants in rows, instead of in bunches to suit large pots; the latter plan being, perhaps, the best where large pots are used for covering when forcing. The lifting the roots is by far the most economical plan as respects material. When we had not a Mushroom-house we used to make a cartload of hot tree leaves, with a bottomless box and a lid placed over it, and covered with litter, produce more cutting than we could have obtained from some waggonsloads of fermenting material placed over the roots out of doors. Then the kale could always be examined easily and cut clean; and before it was drawn so long as to resemble whip-lashes. Nice stiff heads from 5 to 7 inches in length are what we like to see, and as white as possible.

Asparagus.—Unless particularly wanted, we shall take up no more roots to force this season, as for several years we have taken up more than the usual quantity. Where fermenting material can be had, one of the best plans after this time is to have beds surrounded with open brickwork, so as to force them from linings every other year—that is, grow a bed one season without cutting any, and the next season cut all as it comes, until Asparagus may be had from the open ground. The summer growth, and then the next season's growth uncut, if the bed is well enriched at the surface, and a manure waterings, with a dusting of salt, given in summer, ought to make the cutting good every alternate year. Even when a bed is taken up to force, if it can be spared the previous spring without cutting from it, the roots will be in better order for forcing in winter. When we used to have more fermenting material, we had some narrow beds, with a deepish trench between them, and the trench was filled with leaves and warm dung, and the beds were roughly covered with some old sashes, resting on pins or pots. It was necessary to top-dress such beds when gathered from, and remove the dung from the trenches to prevent the roots running too much in it, which would have injured the crowns, when the trenches were deepened in spring, for accelerating the crop. All such methods may be tried for forwarding crops, but for forcing early nothing beats taking the roots up and packing them in a bed above a mild heat from fermenting material. In that case, of course, the roots are fit only for the rubbish-heap, when all the heads or shoots are gathered.

Mushrooms.—Spawned a few yards of a bed, being short of materials to make it larger. The first pieces in the Mushroom-house are now over, the last bearing heavily. These shallow beds seldom continue to produce very long. We still obtain a few Mushrooms now and then from the open shed, where the bed is covered with rough hay and litter. The dung from the first beds in the shed, being nice and dry, has come in for mixing with tiry loam for Kidney Beans in pots, &c. Old Mushroom-dung, when exhausted for Mushrooms, comes in for mixing with soil for many purposes in potting. Besides the enriching material still left, it keeps the soil healthy and open. For top-dressing vegetables and fruits it is also useful, and when flossy and rough it greatly lessens evaporation from the surface.

Planted a frame with strong Cucumber plants, and arranged vigorous plants in a pit; also removed from a pit to a frame a lot of Melon plants to keep them growing on in pots, as we can as yet find no room for them where heat can be applied to suit them. Pricked out lots of Lettuces, Cauliflowers, &c., where a little protection can be given them, to be afterwards transplanted into the open ground when larger and stronger plants. Our winter-protected Lettuces are now nearly over, and therefore will lift with good balls some of the strongest plants that have stood the winter, and plant either in open spaces in the orchard-house, or between rows of Potatoes under glass.

FRUIT GARDEN.

Pruned, tied, and nailed when suitable; thinned, topped, and secured Raspberry canes. We are afraid to give a final pruning to Gooseberries and Currants until we see how the birds leave the bushes.

Orchard-house.—The buds in the orchard-house are now swelling, and a number showing the pink colour. On Wednesday, and on similar bright sunny days, threw water whitened with whitening over the glass, just to spatter it a little and prevent the sun heating the back wall so much. If the buds can be kept from opening for a few days longer they will be all the safer if a sharp frost come. We do not expect that we shall have it very severe, and therefore we have removed all the stubble and litter that covered the pots of fruit trees in the house, and forked the surface soil for 2 or 3 inches deep, which enabled us to see where it was driest. Placed a surface-dressing of hot dung all over, and watered when necessary, having watered now in the course of three weeks two-thirds of the ground monopolised by the roots. After watering threw a surfacing of nice fibrous loam over all, which will give a clean neat appearance for the summer. Kept the house rather close for a day or two after placing in it Peas in pots from the Peach-house.

Filled four lights of a frame with Strawberry-pots, with just the mildest heat from some tree leaves beneath them. We have been obliged to move such pots several times and to several places during the season, owing to mice, and in some cases rats, attacking the buds, eating them right through. Watered the pots in Peach-house and elsewhere in bloom, setting, and swelling, with manure water and clear water

alternately. General temperature of Peach-house from 48° to 55° at night, and from 55° to 60° in dull cold days, and from 75° to 80° in sunny days, the extra heat coming chiefly from the sun. Sprinkled the trees after a sunny day, and shut up early. There is little danger of drawing up weakly from sun heat. Stopped Fig-shoots in Fig-pit, have not yet thinned them or pruned finally. Thinned early Grapes in pit, and regulated others. Pines showing fruit should have a nice moist bottom heat, and a somewhat dry atmosphere until the flowering is over. A bright sun is the great means of making all right. The less shade given to any growing plant the better, unless it is a plant rejoicing in shade or subdued light.

Melons.—This, on the whole, is fine weather for early Melons where they can be put out in good heat, in pots, pits, or frames. Of all plans for producing sound heavy Melons—that is, heavy like lead for their size, growing a plant in a pot, say 14 or 16 inches in size, is the best. The curbing of the roots, and the more thorough elaboration of the sap in the leaves, are the only reasons we can think of for such a result. The next best mode is planting out in a bed from 2 to 3 feet in width, and at least 20 inches in depth, with a space for the stems and leaves of at least three times that surface. Minor details of training and pruning, or rather disbudbing, have frequently been alluded to. A very suitable temperature for Melons is, for bottom heat from 80° to 85°, top heat at night averaging 60°, in dull days from 60° to 65° and 70°, and in sunny days, with air given early, from 70° to 85°. It is only in sudden changes from dull weather to bright that shading will be required, and it should not remain a moment longer than it is needed. All shading weakens the plant.

ORNAMENTAL DEPARTMENT.

As weather was suitable wheeled manure on flower-beds—that is to say, what little we could spare. Dug and ridged beds intended for bedding plants, and threw the rotten manure chiefly on the top of the ridges, &c. Swept walks after frost and snow, rolled the lawns, and pruned evergreen and deciduous shrubs.

Spreading the manure on the surface of flower-beds and allowing it to be there for some time before it is dug in, or rather pointed in, has been followed by some other gardeners, some of whom are blamed for doing so as a wasteful practice, and they want to know what can be said in its defence. Well, we consider that this definite plan is the best for securing a definite purpose. If we wanted a heavy crop of Turnips, huge tubers, and huge leaves, then as soon as the manure was placed on the ground we would wish it to be covered up so that the atmosphere should not take away its enriching virtues; but in most cases as respects these flower-beds, it is not large or very luxuriant foliage so much as abundance of flowers and a good start at first that are chiefly aimed at, and, therefore, we seek to attain that object by a little manure, well aired and sweetened by exposure to sun and air before it is pointed in just below the surface, that the roots may take hold of it at once and give the plants a start, when they will look after themselves afterwards and never become so luxuriant in foliage as they would do with manure 6 or more inches below the surface. Did we put even the same manure on Carrot ground, we should prefer that to be chiefly placed from 12 to 18 inches below the surface. The same material may, therefore, be used differently, according to the object we have in view.

In cold pits, after the frosts and snows, Pansies, Stocks, Wallflowers, Carnations, Amriculas, and Calceolarias, require air to be given judiciously, and water with still greater care, as until the weather is more settled damping will be the great evil to be guarded against.

This season, for bringing on bulbs, Pinks, Roses, and hardy shrubs, Chinese Azaleas, &c., but little extra moisture was wanted in the atmosphere of the forcing-pit, except in clear, frosty days. The Crocuses we grew in pots this season, for internal decoration, did not succeed so well as usual, though many were very beautiful, and owing, we presume, to the extra wet, they have not come nearly up to the usual mark out of doors in many places. As a whole, evaporating-pans in heated houses have been less necessary than usual.

House Decoration with Plants.—In many mansions at this season will be found bulbs and forced flowers stuck all over the rooms in common red pots. On the principle of fitness nothing can well be more out of place. There can be nothing like harmony or congruity between elegant furniture, mirrors, &c., and a garden pot, even if it should stand in a china saucer instead of the common red earthenware flat. To remedy this the pots are sometimes covered with moss tied on them, or ornamental

paper, such as that representing various kinds of marble, is neatly fastened to the pots. All these plans fail of their object, because the artifice is so easily seen through. Though the truly refined and artistic will ever be in unison, it is always as well that the artistic should not be combined with the tawdry and make-believe. Besides, many plants, as Hyacinths, Tulips, Crocuses, Deutzias, Ferns, &c., appear much better in a group than in single detached specimens. A vase, a box, or a basket, but so arranged that no water shall escape, and in appearance more in character with the walls and furniture of the room, would yield a degree of harmonious interest, when neatly filled, that single plants in clumsy pots could never inspire. Zinc or sheet iron, nicely painted, will be useful and convenient for such purposes. In most gardens there are some nice terra cotta vases in the garden in summer, that are either empty or brought somewhere so as to be protected from snow and frost in winter. These, in winter, might be used with good effect in the mansion instead of pots. All that is required is to cork up securely the drainage-pipe, put a good layer of moss in the bottom, and either pack full with plants in their pots, or take the plants out of the pots and pack with a little soil, and then cover all over with neat moss, dotted with little bunches of V. lts. Beside such a neatly-arranged vase, plants in pots would seem nowhere. When it becomes more common to have fruit trees on dining and side tables we hope it will also be common to have nice vases suitable for receiving and concealing the common pot, which will ever make a sorry figure by the side of fine crystal and silver, not to say gold, plate.

Went on with potting, propagating, and moving and regulating plants as detailed in several weeks lately. All beginners who have much of that work to do should take a little extra pains to have their soil well aired, sweetened, and leated before using it. As frequently stated, many a plant dwindles, and is ere long pretty well eaten up with insects, because when growing in a rather warm room or house the poor tender roots are surrounded with cold clammy soil. Another prevalent error is taking a plant from a hot place to pot it, and leaving it for an hour in a cold place before taking it back. Such little matters often make all the difference between success and disappointment.—R. F.

COVENT GARDEN MARKET.—MARCH 10.

The supply continues good, a steady trade is being done, and quotations remain the same as in our last report. Late Grapes may still be had, and a few new Hamburgs have made their appearance.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross, London, N.—*Catalogue of New Roses, Beaton's Hybrid and other Geraniums, Hollyhocks, Dahlias, &c.*

James Backhouse & Son, York.—*Supplement to Catalogue of Alpine Plants.*

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

BOOKS (A. H. G.).—Those you name are published by Messrs. Smith, Elder & Co.

MR. BRILL'S ROGERS.—We presume you mean Mr. Bull, Nurseryman, King's Road, Chelsea.

SEEDLING CINERARIA (A. F. S.).—The petals are free from the notch which flowers deprecate, otherwise there are many similar in color, and others far superior. No judgment can be formed of any plant from a single flower.

GARDENER'S DAY'S WORK (Bob.).—From 10 to 10½ and 10¼ used to be the number of hours in London. We believe most people have their own arrangements, and all sticklers to time should settle that beforehand. Of course gardeners do not work these hours in winter, and very long hours are generally an injury even to the employer.

POTATOES FOR PLANTING AN ACRE (Lalshoboy).—How can we tell how many you will require without being first informed what sized sets you intend using, and how far apart in the rows, and what distance between the rows? If the sets weigh 2½ lbs., and are placed 9 inches apart in each row, then if the rows are 1½ inches apart, you will require 60,720 sets, equal to 43 cwt. If the rows are 3½ inches apart you will require 22,222 sets, equal to nearly 2½ cwt. From these data you may calculate the quantity you will require.

ESSEX RIVAL PEAS.—We have had several letters from "A GARDENER FROM LEICESTERSHIRE," "PISUM," &c., and we decline to insert any more upon the subject. The Committee of the Royal Horticultural Society have decided to repeat the trial this year, when the public will be able to judge for themselves.

SOWING CINERARIA MARITIMA (P. P.).—The seed, sown now in a greenhouse, would not vegetate unless the temperature were at least 50°. We should recommend you to defer sowing until you could command a temperature of from 55 to 60°, and a bottom heat of about 70°. Sow the seed in pans of good light turfy loam two-thirds, and one-third leaf mould, and not very thickly. When the seedlings are up give abundance of air, and do not overwater; yet keep moist, and when two or three rough leaves have been made prick the young plants off at an inch apart every way; place again in shade, shade until established, and grow on until the middle of May; then harden off and plant out in the first week in June. If the seed be sown early this month and treated as above, fine plants will be the result, only they will not be so silvery as those which are older.

DISBUDDING ROSES (C. A. M.).—It would be desirable to limit the flowers to one on each shoot, and to allow none to expand except on the vigorous shoots. This would strengthen the trees materially and assist their becoming speedily established, and the denial thus exercised will be amply repaid in after-years.

SHRUBS UNDER A HORSE CHESTNUT (Amateur).—Aucubas are the best of all shrubs which we have tried for planting in shade under trees. Laurustinus does fairly; so do the Alexandrian Laurel, Butcher's Broom, Ivy to run along the ground, Berberis aquifolium, repens, Darwinii, Dulcis; common Laurels, Hypericum or St. John's Wort, Common Yew, and Periwinkles of sorts.

PLANTS FOR PARTIALLY-SHADED LOCKERY (H.).—Aubrietia deltoidea, Alyssum saxatile, Iberis Tenoreana, I. sempervirens, Arabis alba, Wallflowers, Cheiranthus Marshalli, Campanula garganica, Cerastium tomentosum, Cineraria maritima, Convolvulus sepium roseus, Dianthus deltoides, floribundus, and plumarius, Draba azoidea, Fumaria solida, Glechoma hederacea foliis variegatis, Sedum acre, Forsterianum, and spuriatum, Saxifraga Rhodi. polia, hypnoides, palmata, and alizon. Phil. x vernis, Orobanch vernus, Lotus corniculatus flore pleno, Linaria cymbalaria, and its variegated variety, and Alchemilla alpina.

PAINTING HOT-WATER PIPES (An Old Subscriber).—Painting with linseed oil and lamp black will not prevent the free radiation of heat, but rather promote it. In reply to "C.H." on the same subject we would not advise such work being done now when the house is at work and the weather is cold, as the fumes sent off will be apt to injure tender plants. Better wait, at least, until the days are long and more air can be freely given; better still, wait until the risks of the season are over. To "N.Y.Z." also on the same subject, we would say that the best time to paint pipes is when the house is empty, or when the plants are comparatively at rest; and the best mode then to do it is to have the water in the pipes heated to about 140°, and then the paint goes on thin, and soon becomes dried, and the thinner the better, provided all is well covered. We like as well when there is a little lead in the paint.

INSECT ON VINES (A. B.).—The insect on the neglected vines is the mealy bug (Coccus adonidum). Use no time in applying the usual mixture of soft s. ap. sulphur and tobacco water by means of a hard brush.

CONSERVATORY BUILDING (A Subscriber).—We have no recollection of any one building with iron and without paint.

MANAGEMENT OF A HOTHOUSE (A Local Subscriber).—To publish all you ask for, to teach your gardeners, and all the culture numbers of this Journal, Bay Keane's "In-door Gardening" you can have it free by post from our office for twenty postage stamps. For full directions for stove management during each week in the year.

HEATING BY HOT WATER (Z.).—We do not think that a tank would possess any superiority over pipes for heating your stove and Cucumbers. If you have movable openings in the tank, you can admit vapour from them into the atmosphere of the house when the water is not so warm as to cause the vapour to scald. This is almost the only advantage of a tank in such circumstances. You are quite right in concluding that in heating the two houses from one fire the tank must be lower and higher than the pipes. The tank would then act as a cistern to supply the boiler. A tank 2½ feet wide, with sides from 4 to 6 inches deep formed of radiating material, such as slate, brick, or better, iron, covered with slate or iron, the sides exposed, and with a few openings in the top, would give you enough heat for Cucumbers and stove plants after March, but would scarcely be enough in winter. You would want besides one or two four-inch pipes. Were we to have such a tank ourselves, unless there were reasons for having a tank, we would use two four-inch pipes for hot water heat; but if we resolved on having numbers all the winter, then we would have three pipes for hot heat, it matters but little where placed, but it would be well to have one at least at the back of the house. Of course such a house must be heated independently of the greenhouse. For this two pipes for the length, or a little more than 60 feet, would keep the house safe in winter. We would prefer three, and then if you wished you could keep up a higher temperature. We presume you know how to arrange the pipes and furnish them with air-vents if on different levels. It does not answer so well to take water from a large tank to heat other places. In your case the simplest plan would be to take the flow-pipe into a cistern, say 20 inches square, higher placed than any of the pipes, and from thence take a flow for top heat, a flow for bottom heat, and a flow for the greenhouse, to be regulated by plugs, all having a return to the main return-pipe.

EXCLUDING FROST FROM OLD SUBBERS (N.). Kind of stove ought to be used for heating a greenhouse, unless the product of combustion are carried into the open atmosphere. We would prefer a common iron stove with a small pipe leading out of the roof or through the back wall. You have only to put in a thin slate with a hole out in it, or a piece of sheet iron instead of a square of glass, if the pipe go through the roof. We would prefer the pipe to go from the side of the stove near the top, and not from the top; and if the top is level an iron vessel could be placed on it to be supplied with water. This is the simplest and cheapest mode of heating such a house. The next cheapest and best is provided you have a tiled or brick floor, to have a small flue below the floor.

REMOVING VINES FROM POTS (Hem.).—In most cases we would shake all the earth from the roots of Vines in pots before spreading them out for planting. As to Fern culture, you had better buy the "Fern Manual," published at our office.

LOBELIA SNOWFLAKE.—I bought a 2s. 6d. packet of the seeds of Lobelia Snowflake, which were sown a month ago and plunged in a hotbed for Cucumbers, a piece of paper being laid lightly over the soil. I speak within the mark when I say that ten or twelve dozen plants have come up. I think "Nemo" and friends may still expect their seeds to come up; Lobelia seed will often wait the four or five weeks before appearing if not kept warm and moist.—W. C. Two other correspondents write as follows:—"Did 'Nemo' get Lobelia seed from 'E.H.'? I bought 'Snowflake' a large seed pan full of healthy plants.—E.H." I bought 'Snowflake' seed on the 15th of January and sowed it a day or two afterwards in a common seed pan, securing perfect drainage; and covering the seed very lightly with white sand. I then placed the pan on a shelf in an early vinery. It certainly was six weeks before I saw a vestige of a plant; but it has come up quite as thickly as I could expect from the small quantity of seed sown, and is now growing well. The Lobelia speciosa, which I sowed at the same time, is nearly ready to prick out. A nurseryman in this town sowed a packet of the Snowflake in a rather strong bottom heat, which came up much more quickly than mine. If 'Nemo' has not sown his too deeply he need not despair.—J. M. B. "Since writing last week a few of my Snowflake Lobelia seed have come up, about a dozen.—Nemo." "If 'Nemo' will favour us with a call, we shall be happy to show him some pots sown from the same sample as that sent out, in which the seedlings are as thick as the hairs on a cat's back. We have sown it at different periods, and a packet has always yielded from 500 to 700 plants.—J. & C. LEE, Royal Pineapple Nursery, Hammerwich." We have a dozen similar letters, and need not insert any more.—Eds.

PEAS, PRESERVING GREEN (H. S.).—They may be preserved until the next spring if some of the summer crop are treated as follows:—"Pick them when full grown, shell them, dry them gently but thoroughly, and then store them in canvas bags in a dry place. When required for use soak them in water for a few hours until plumped up, and then boil them." The following mode has been reported to us by a person well qualified to judge of such matters as being very successful:—"Carefully shell the Peas, then put them in tin canisters, but no larger ones; put in a small piece of alum, about the size of a horse bean, to a pint of Peas. When the canister is full of Peas fill up the interstices with water, and solder on the lid perfectly air tight, and boil the canister for about twenty minutes; then remove them to a cool place, and they will be found in January but little inferior to fresh, newly-picked Peas. Btting is not so good—at least, we have not found it so; the ear gets in, the liquid turns sour, and the Peas acquire a bad taste." The "Garden Manual," which you can have free by post from our office if you enclose twenty postage stamps with your address, contains the information you mention. A larger work on garden plants is prepared.

MEASURES FOR CORNELL.—"A quarter of Oat" is a quarter of a peck. "Cent Garden Measures" are in our No. 22 published January 2nd last.

GOOD BEARING FRUIT TREES (A. Q.).—(Insects) Flanders Pippin, Striped Beeching, Blenheim Pippin, Pear; Conqueror Golden Court. These four fruits named by you are all good bearers. The Blenheim Pippin is of luxuriant growth, and is some time before it bears down, but when it begins bearing is very prolific.

FERNS IN WARTIAN CASE (Irish Man).—The Ferns will continue to damp off if you cannot admit air at one of the sides as well as at the top. Circulation of air is essential. The Fern had better be turned out from the pots. The plant you have sent is Saxifraga cuneifolia, or Tufted Alpine Saxifrage. It is a native of the highest mountains of Wales and Ireland.

CUCUMBERS FOR EXHIBITION (A Subscriber).—Improved Manchester Prize and Hamilton's Surprise are as good as any others.

GREENHOUSE VINEY (*A Subscriber, Ballinasloe*).—Ist, We have no doubt that the greenhouse viney will answer very well if you have sun in summer from 8 a.m. to 4 p.m. It would answer better still if you could raise the back wall higher than 14 feet—say 16 feet; but 14 feet according to your own showing will do. The front of the house, to look well from the living-house, should be 6 or 7 feet in height, and of that 3 feet at least may be brick wall. The front sashes should be hinged to move, and three or four short sashes at the top should be moveable; all the rest of the roof may be fixed. 2nd, Suppose you raised your wall in front 3 feet, you might make the most of your border above the flags now in the yard by raising the border at back, close to the sill. Then, instead of taking the Vines through holes in the wall, we would build the wall on arches, run a wall along inside, leaving a space in front at least 3 feet wide, and fill that with good soil as high as the border outside, and there we would plant the Vines, and thus have all the stems under control, and the roots could go out as they liked. This border would do for setting plants on, or you might have a sparred trellis all over it with a wall behind it; you can arrange the rest of the house by stage or otherwise. The very best arrangement would be a walk all round, a bipped stage in the centre, and the back wall covered with Camellias, Acacias, &c., or with shelves if many plants were to be stored. 3rd, For such a house we would be inclined to use from six to seven Vines, and according to your fancy they should be these—*one Bowood Muscat* where the heating pipes come in, *one Mascat Hamburg*, *one White Frontignan*, *two Black Hamburgs*, and *one Esperone*, and if a seventh, *one Royal Muscadine*. 4th, With what you tell us of the circumstances we cannot be so sure of the Roses succeeding on the trellis on three sides of the court; if there are walls on the sides would they not do as well on them and thus give you more space? We have little doubt that by removing the flags and the concrete, and putting in 3 feet of good soil, your plants will thrive if they have enough of sun and air. Of course they will receive much less sun than the greenhouse, which will stand at the north end of the paved court. A paved court is generally more comfortable behind a house, especially when shaded, than either grass or gravel. We would just throw out the hint, before raising the flags, whether vases or baskets would not answer the purpose better. Nice little beds might also be made above the flags, high enough to let the flags remain, or so low that the flags could be removed only beneath the beds. Such beds or vases, we think, would look more artistic than mere beds of earth.

HOT-WATER APPARATUS FAULTY (*A Seven-years Subscriber*).—We do think you should make a complaint and have the tradesman to see the heating apparatus if the following suggestions do not help you. 1st, See that the fire is all open and clear, then keep the damper open and the ashpit door open until the fire take good hold, then shut the ashpit door, and when the fire becomes bright shut in the damper, not so as to leave a space that would admit the blade of a knife, but from half an inch to a quarter. To save trouble you might drill three or four quarter-inch holes in the damper. 2nd, See what is said about deficient piping in "Doings of the Last Week," page 186. In such cold nights as we have lately had, we think the two pipes, 30 feet we presume, in the house did very fairly in keeping up a temperature of 45°, and that under the circumstances would be high enough for a conservatory. To have a heat in cold nights of from 50° to 60° in such a house with front, one side, and top of glass, would require four rows of piping, or 60 feet. 3rd, We cannot see why such a fire should involve smothering with smoke, and running to it eight or ten times in an evening if at all rightly managed. We have seen a person lighting a fire with the damper in. Most likely you must indocrinate the cook with an interest in the plants. The flower you enclosed is *Abutilon vitifolium*. The sticky excretion on the leaf is "honey-dew." You can remove it either by sponging or syringing.

HEATING A GLAZED HOUSE (*W. H. S.*).—We are not sure from your description whether your house is to be a true span—that is, 6 feet on each side, and 10 or 12 at the apex, or whether it is to be a lean-to with a hipped roof on one side. If your levels are all right you can easily heat such a house from the kitchen boiler alluded to, and you would have no occasion whatever for a fine. Pipes of the requisite length, and 1 inch in diameter, to screw into the boiler, one near the top and one near the bottom for the flow and the return, will do very well. These can be screwed at the other end into cap socket joints that will fit into four-inch pipes. From 30 to 60 feet of these four-inch pipes will be necessary, according as you wish merely to exclude frost or have a higher temperature in winter. Grapes may be grown; but whether in pots or otherwise, the more you have of them the less you will have of other things. For a cool house *Royal Muscadine* and *Black Hamburg* will be best.

FLOOR OF GREENHOUSE (*H. G.*).—For a greenhouse the door may be slate, flags, pebbles, or even the earth. If a certain part is floored for paths, the earth or pebbled gravel would do as well as anything, and would always be easily freshened up. For Peach-houses and vineries we like earth as well as anything; and the floor will always look fresh when fresh raked, or a fresh sprinkling of clean soil added to it. If the trees are planted outside, the floor may be paved or tiled with advantage. We fear we do not catch your meaning.

SEEDING-OUT A Young Garden.—To produce your colours—1, *Perilla nankinensis*, or *Aristo Improved Verbena*; 2, *Tom Thumb Geranium*, or *Beule de Fer*; 3, as proposed, white Variegated Sage, white *Verbena*, or *Alma Geranium*, with the flowers removed; 4, *Purple King Verbena* for purple, a dwarf *Ageratum* for lilac blue; 5, *Lobelia speciosa*; 6, *Calceolaria Aurea floribunda*, or *Auranta multiflora*, as you wish it to be 10 or 15 inches in height. Plant *Lobelia* from 4 to 8 inches apart; all the rest a foot apart.

GIANT WHITE PETUNIA.—We shall be obliged by information in answer to the following:—"I have long tried to obtain a plant of the Giant White Petunia, having seen one once at Southampton Nursery, quite as large as the purple one, which they call the Great Western in these parts. Mine are of the size of a small tumbler, and I think if the white one could be as easily raised they would make a very beautiful bed together. I sent for some seed of a kind called *Petunia grandiflora alba*, but it proved to be only the common white one, which grows self-sown in my garden. Under what name ought I to ask for the large-flowered, and where can I procure it? Last year the Giant Purple one perfected its seeds, which I never did before, and I have a pan full of seedlings now coming up in my greenhouse.—E. S. B. G., Teignmouth."

FLOWER-POTS (*A. and Others*).—We must refer you to the advertisement in last week's Journal, inserted by Albert Downs, Edmund Hill Pottery, Glastonbury.

RHODODENDRON FORTUNEI.—We shall be obliged by information in answer to the following:—"W. D., a great admirer of *Rhododendrons*, wishes to know if any of your numerous correspondents has yet bloomed *Rhododendron Fortunei*. I bought one when it was sent out first, now a large plant out of doors, and have another large plant in a pot in the house, but neither of them appears likely to flower. I bloomed *Aucklandii* beautifully last season, a much younger plant than those of *Fortunei*. If it has bloomed in this country is it an acquisition of any value, or not? What are the blooms like?"

SOWING PICEA NORDMANNIANA SEED (*H. & F.*).—Sow the seed thinly, the present time is as good as any, in pans or boxes of rather sandy soil made firm at top, and if you take the trouble to partly fix each seed in or rather on the top of the soil, we would not advise any covering beyond a little moss laid loosely over the surface, to prevent the sun parching the seed while in course of vegetation. A cold frame will do very well, or the pans may be set in a gentle heat if you wish to hasten germination. Remove the moss by degrees as the seed vegetates; but before that keep a sharp look out for mice, which prey sadly on the seed. Water moderately when dry weather sets in, until then little will be wanted. We would prefer a cold frame to a hot pit for these plants, and more seed, when new, will be found to vegetate in this way than when sown in heat.

DISEASE IN SILVER FIRS (*H. J.*).—We are sorry we cannot offer any effectual remedy or preventive to the disease you complain of. We saw some trees similarly covered with a white substance in Kent a short time ago. They were about 40 feet or more in height, and had until the last year or two appeared in the most robust health, but were absolutely dying, and some had succumbed. We did not examine the white substance by which the stems were covered; but from its appearance we supposed it to be of a resinous nature, and exuded from the tree, showing that something was wrong either at the roots or with the foliage, in consequence of which the balance of sap and its absorption was not maintained. Of course these views may be erroneous, as we had not the means of examining the trees closely. We have, however, seen a white resinous substance ooze out of an *Aranea* during an unfavourable season, and the next year the tree was all right again, showing that the evil was only temporary; but we much fear that the Silver Fir is worse affected, and we will make further inquiry in the matter.

RHODODENDRONS FOR FORCING (*G. B.*).—The best we have grown of the early-flowering hybrid *Rhododendrons* were—*Ruseellianum*, crimson scarlet; *Wellingtonum*, bright scarlet; *Stamfordianum*, rosy scarlet; *Caucasianum album*, white-spotted; *Nobleanum* in scarlet, rose, and light varieties; *Perpicuum*, white; *Campanulatum hybridum*, white; *Altacresense*, scarlet; and *Broughtonianum*, rosy red. Varieties of *R. catawbiense*—*Everestianum*, lilac, spotted and fringed; *Glennyanum*, whitish; *Grandiflorum*, bright deep rose; *Roseum elegans*, bright rose; *Roseum superbum*, deep rose; *Purpureum elegans*, purple; and *Album elegans*, waxy white, green spots. Of the late-flowering hybrid scarlets—*Victoria*, dark plum; *Blandyanum*, deep crimson; *Atroroseum*, blood red; *Alarum*, white, deeply edged with light scarlet; *John Waterer*, glowing crimson; *Maculatum purpureum*, purplish rose, much spotted; *Towardi*, rosy lilac; *William Downing*, rich dark rose, intense blotch; *Lefevreanum*, purplish crimson; *Coriaceum*, white; *Brayanum*, rosy scarlet, with lighter centre; and *Hogarth*, rosy crimson. Of the dwarf small-foliaged kinds—*ponicum odoratum*, and *myrtifolium*, and *R. hirsutum*; all pretty, free blooming, and sweet.

TRAINING WEEPING ASH TO FORM A SUMMER-HOUSE (*E. C.*).—We should advise you to have poles 9 feet long, fixed in the ground to the depth of 2 feet, first charring the thickest end for that length, and coating it whilst hot with coal tar. Fix the poles in an erect position, a yard apart, on the circumference of a circle, each 4 feet from the stem of the tree. They may be 3 or 4 inches in diameter. Their tops being sawn off level, the half of a pole of the same diameter should be nailed, flat side downwards, on the heads of the upright poles. The branches of the tree are to be raised and put upon the rail thus formed, fastening them with a piece of tarred string. If the rail is so high that the branches cannot be brought over it without breaking, the poles must be less in height or nearer the stem. On the side where the branches are thinnest a doorway may be formed, and any available branches trained in that direction. In a few years you will attain your object.

HEATING BY GAS (*A Constant Reader*).—The following mode we published in our First Series, Vol. XIII., p. 24, where an engraving is also given:—"The apparatus consists of a burner—a ring of brass tube, 2½ inches in diameter, pierced with fifteen small holes—placed 4 inches above the level of the floor. Over the burner is what may be described as an inverted galvanised iron trough, 9 inches wide, 7 inches deep, and 5 feet long, resting on four legs 4 inches high. The burner is placed under one extremity of this trough; from the other end runs the chimney, which is of three-inch galvanised iron piping, the joints of which are not cemented. This rises 5 feet, and is then carried across the house 12 feet, and finally makes its exit in the kitchen chimney. Placed on the top of the trough over the burner is an evaporating pan, containing about three gallons. This arrangement, if not ornamental, is cheap and useful, and, with a little expense, may be made more elegant; at any rate, it is entirely removed during the season when the more attractive flowers of summer invite visitors." If you chose to have a small boiler and pipes for circulating hot water, and heated by gas, you will find a drawing and description in No. 94 of our New Series of this Journal. We will publish some notes and drawings shortly.

SOWING ANNUALS (*S. E. N.*).—Seeds of *Tagetes sigmata*, *Phlox Drummondii*, and the *Ice plant*, may all be sown in pots in gentle heat, in the course of the present month, hardened off, and planted out towards the end of May, when all danger of frost is past. The annual *Lupines* may be sown out of doors, when the soil is in good condition, about the beginning of April. If required to bloom early, they may be sown in a little heat, or out of doors in the present month. The plant is *Aescia decurrens* var. *mollissima*.

EMERGENCE (*G. B.*).—We never advise upon this subject. Too much depends upon circumstances of which we know nothing.

ACUCIAS (*W. R. L.*).—There are male and female plants in all the species, so we cannot aid you. Of course plants of both sexes must be present to obtain fertile seed.

NAMES OF FRUIT (*E. W. A.*).—*Apple*—1, *Beauty of Kent*; 2, apparently the same, but of a paler colour; 3, *Lewis's Incomparable*.

NAMES OF PLANTS (W. M. S.).—We cannot name plants from seeds. In all cases a flower should be sent. The usual greenhouse-treatment will suit your Swan River seed. (T. Suberberg).—We cannot name a plant from seeing three small dried leaves. (T. Jones).—Again you must be

disappointed. The or hid flower was quite black, and there are several of the Calanthes so nearly alike that a perfect and fresh bloom must be seen to justify identification. The flowers should be placed between layers of damp moss and sent in a small box.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending March 10th.

DATE.	BAROMETR.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun... 4	29.727	29.542	42	28	40	40	E.	.00	Hazy; fine; dusky haze; fine; slight frost.
Mon... 5	29.719	29.621	41	25	41	40	E.	.00	Cloudy; fine; overcast; slight frost.
Tues... 6	29.457	29.210	44	26	40	40	S.W.	.20	Fine; rain; fine; frosty.
Wed... 7	29.661	29.175	45	25	39½	39½	S.	.02	Hoar frost; showers; dusky clouds; fine at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

A DAY AT LINTON PARK, KENT.

THE SEAT OF THE VISCOUNT HOLMESDALE, M.P.

(Contd. from page 190.)

Back we turn toward the house, and then verge to the right, and are in front of a group of most beautiful Spanish—black and glossy; as they proudly stand on the green turf. I ask, Can any fowls be more beautiful? A Spanish cock, if well-bred, looks such a gentleman, and the hens such high-born dames. I look on and am enamoured. I am glad that the General admires these noble birds.

We next find Lady Holmesdale's pet Dorking hens, her largest birds, the heroines of many and many a poultry show, which, if they could write their travels, could tell of more admiration expressed, and fervently expressed to them, than any ball-room belle in the country—what attention had they not received, what praise heard of their beautiful selves. "You will see poultry to perfection at Linton Park." These words kept sounding in my ears, just as a line of poetry will do sometimes, and I kept giving an inaudible assent to their truth.

Now we are bound for a distant part of the park, so southward we stroll, now and then coming to a stand-still on an oozy bit of turf (Oh! this wet weather), and being obliged to alter our course from a straight line to a curve. Admiring the scenery, and falling more and more in love with Kent. I come to a wood where more Dorkings are picking about—one an old cock, which had evidently seen his best days; but Lady Holmesdale particularly wished me to see a young cock at a walk at one of the abovementioned medd cottages. So diving into a thickish wood, and climbing the park paling, I stand, or rather try to stand, for 'tis a giddy height, and an uncertain foothold, and I obtain a view of the airiness the road and a cottage garden, it being driven in sight, much to its disgust, by the cottager, and I with huge strides and wide wings escaping as soon as possible. This cock is, perhaps, the most promising bird which her ladyship possesses; but I owe him a grudge, as the sequel will show.

We now turn back, and in a direct line seek the house, ascending the hill and first a very gradual ascent, upon which the mansion stands. No country house could have a finer position, and few possess a finer frontage. And now I noticed a peculiar bay yellow light lining upon the park, and gardens, and house front, not unlike that often pictured by Turner, particularly in his view of Petworth Park, now in the possession of Lord Leconfield at Petworth House. As we walk on I admire very greatly a number of slender pointed Hamburgs, which, as far as my individual taste went, I preferred to any poultry seen at Linton. Further on, and in a no yellow haze to admire, but a sharp snow, and then a tremendous down-fall of rain—a piteous pelting, hard-blowing storm. Oh, that Dorking cock! 'tis his fault that his noble mistress will be drenched, and we all here for London. However, that is nothing, for it is always the case with looking at poultry. Sheltering, but vainly sheltering, by the trunk of a tree for a minute or two, where, most unconsidered of me, quite near to us, were a number of Dorkings; but in vain—we must run for it; and the gallant General, who never ran before his country's enemies, runs before the attack of Pluvius. Drip-

ping and breathless, we reach at last the kindly shelter of the house. Welcome secure shelter, drying fire, and satisfying food, three blessings which soon put all to rights.

After luncheon I am shown the cups won at different times by Lady Holmesdale's birds. They (the cups), are brought in upon a large tray—a very large one, and present a very bacchanalian appearance. By the way, could not poultry committees give silver prizes in some other than the cup form? What can be done with them? Look at my friend Mr. Robson with his forty or fifty cups. They would be very suitable if every fancier were like the most paternal gentleman of whom the poet says—

"Father of twenty children was he, and more than a hundred Children's children rode on his knee."

Then each child and every favourite grandchild could have each a cup; but we are not all, happily, so very patriarchal. Lunch being over, and the weather again beautiful, the various guests at Linton scatter in search of recreation or exercise. My noble host most kindly proposed to devote himself to me for the afternoon.

First, I am shown a photograph of the garden in its summer trim, and very lovely it must then be. Even now, owing to Mr. Robson's skill, it presents (I am speaking of the bedding portion), a picturesque appearance as seen from the windows, for the large led shows distinctly three colours—white, red, and black; and yet, though the effect is good, it is caused by lumble material—cockle-shells, broken red brick, and cinders. By these means the eye is pleased, and we are spared the cold-looking bare mould.

Before descending to the terrace I must say one word about the interior of the house. The public rooms are handsome and well proportioned, and all opening into each other. The effect of this, seen from end to end of the whole length of the house, is very pretty and pleasing. In the dining-room hang the portraits of her ladyship's ancestors, the Lord and Lady Cornwallises of other days—one that of a former Governor-General of India, another in close pal robes. How often the church is entwined with the peerage! Then bright fair eyes look down upon us—eyes long since closed, and rosy lips and rounded arms that had admirers in their day, doubtless. Then there was the full-length portrait of a youth, a mere boy, fair-haired, and fresh-looking as a mountain daisy; but his antique garb hid the tale of his being no more in the flesh. Oh, triumph of the painter's art! The picture lives and glows, almost breathes, when the reality is but dust. I delight in a room full of family portraits. I could sit down and write a good sermon there. I love the company of such—they supply thought. I like, too, the varied dress, telling of the time when each one lived, and perhaps, as here, there is an historic name and face, one of England's worthies, and I feel, "I, too, speak your language; I likewise am an Englishman." But while I am moralising his lordship is waiting.

Just in passing Lady Holmesdale points out to me a little and most closely filled conservatory of semicircular shape, at the one extreme of the suite of rooms, as the dining-room is at the other.

To the garden. Here in the soft air of Kent, and in a spot most sheltered, I found a very fine cork tree, finer and less ragged-looking than the two at Godwood. If my memory is correct, being an evergreen, and in such a stormy snow-falling country as England, I was surprised to see it without

a single break—not even one limb is gone. Next we turn into the large and new conservatory, a fine structure, which, when the iron pillars become clothed with creepers, will be fairy-like. Through it we reach the fern-house, and oh! the beautiful ferns, from the palm-like tree ferns to the little wee ones at my feet, every gradation of size and form. What a charming grot to sit and read in! But I must say no more about it. I am not a "FELIX-FÆMENA." I neither have her knowledge nor hold her pen. Greenhouses, vineries after vineries, garden after garden came next, until we stroll along the terrace, then plunge into the mazy walks among the shrubs. It is worthy of remark, that the choicest shrubs grow very vigorously at Linton, soon joining each other, growing across paths, so that I found many new walks planned, simply because the others were not passable. Lord Holmesdale seemed to be keenly alive to the pleasures of his garden, and knew each tree and flower as well as loved them—perhaps loves because he understands them, for love is the child of knowledge. His lordship took me to Mr. Robson's cottage, the *beau idéal* of what a head-gardener's house should be, but he was not at home. We found him, however, soon afterwards, among his men superintending the restoration of the paths, the materials of which had been literally washed down the hill by that most drenching shower. (Oh! that Dorking cock!) There is no gravel in this part of Kent, so the walks are coated with broken shells from a river's bed near. We next, leaving the paths to be righted, walk on to the newly-laid-out garden between the mansion and the church, which in summer will look grandly, having such a ribbon-border so wide and long.

I pause now and then to feed upon the view lit up by a bright watery sunshine, and admire nearer at hand the shrubs, with the yellow sunlight upon their still wet leaves. But I must be away in order to catch the train at Maidstone. I would fain have lingered, but—that train, and to jog memory there stands the carriage at the door. So I am off, and presently the park is left and we break out into the high road. Hop poles on all sides far as the eye can reach. Oh, ye teetotalers! never one of ye retire to live in Kent, you would not have a single happy hour. Marks of old inhabitancy meet one at every few hundred yards. I see Kent bathed in yellow sunlight, that peculiar light which comes after a very heavy shower. I am one who believe that a merciful compensation runs through all things. The heavy unpleasant rain, then the brilliant sky, and the more golden sunlight. Wordsworth describes in two lines what I saw—

"The rain came heavily and fell in floods,
But now the sun is shining calm and bright."

He might have added all the brighter for the past rain. Sunset is fast coming on. I reach Maidstone just in time, jump into a carriage, and am all to myself—just what I like at the end of a day's pleasure, then I can ruminate uninterruptedly upon the past. Soon the stars came out one by one, and nothing caught my eye save the flaring gaslamps of the stations, then came the lights of the houses, then of the streets, and I am again in busy, bustling, thronged London.

A few concluding words upon my day at Linton Park. "I saw poultry to perfection," and beautiful gardens as well, and I spent a day, one of the few I should like to live over again—but that is a heathen wish, so I recall it, for it is our part to press on to a better world. I was most kindly received, and my noble host has the happy and enviable gift of making a stranger feel at once at home. England has an aristocracy fulfilling its duties as a class (and I do not speak without some knowledge), as thoroughly well as any other class in the community. They may now-a-days invite comparison with any class. They build the comfortable cottage, making the poor man happy, and they have, where they are known, the respect of the middle and richer classes. They give time as well as money to help others, and in urging forward what is good, and they fulfil their part of the world's work manfully and well. I hope, therefore, never to see our dear old England Yankeeified, but that its nobility will always have their just and proper influence. Blatant levelling demagogues (I have come across several), are seldom men who fulfil their own duties, while they rail at others, and they are never in taste or feelings gentlemen—from such, and their pernicious doctrines, may we be long preserved.—WILTSHIRE RECTOR.

EGG HARVEST.—I began keeping fowls in December, and from three hens and five pullets I had in December 45 eggs;

in January, 65; and in February, 130: therefore I do not think the weather should be blamed because the fowls of others do not lay. I attribute my success to their having a clean, comfortable roosting-place. I had six eggs yesterday, and seven to-day, and the weather is very frosty.—W. H. S. (*A Schoolboy*).

[A clean roosting-place is very conducive to health; but proper feeding must also characterise your management. We have eggs in abundance now.]

DEFICIENCY OF EGGS.

I HAVE noticed your remarks on this subject. I am inclined to think that breed has more to do with it than the weather. I keep White Dorkings, having come to the conclusion that they are the best of all fowls for general purposes. I have twenty-eight hens, the oldest is ten years old; of course she must not be counted, as she has not laid for two years; the others vary in age from seven years to seven months. Except for a fortnight in November last I have not been without eggs for three years; to-day eleven were laid. I have had several broody hens that I turned off on account of changing my residence, so that I only set my first hen last week. We have so good a supply of eggs that we cannot use all. I feed once a-day on barley, and once on potato-parings boiled and mixed with sharps, and the fowls have a good run. I am a great advocate for white plumage, it keeps the birds warm in winter and cool in summer; and if I could induce others to try White Dorkings I feel sure they would like them, but they must not have puny birds.—B. P. BRENT.

GAME BANTAMS.

WITH every respect for the opinion of "WILTSHIRE RECTOR," I must decline to accept "the great Yorkshire breeder's" letter as setting the question between us at rest. First, I must say that I do not think "WILTSHIRE RECTOR" is quite candid, he now rather backs out of his avowal that Game Bantams are easy to breed (*good*), for I appeal to every reader of his answer to "GALLUS," at page 96, whether that is not what they understand him to mean by what he there says; nay, I will ask "WILTSHIRE RECTOR" himself to read that reply again, and then to say whether that was not what he really did then intend to have your readers infer. Well, I replied, and I gave instances that "WILTSHIRE RECTOR" was altogether mistaken, and I again aver, "the great Yorkshire breeder" notwithstanding, that Black Red Game Bantams are as a rule exceedingly difficult to breed first-class; and I will say further, and echo the words of a very noted breeder of Game fowls who recently wrote me, that "not half a dozen A1 Game Bantams" are produced in a season out of the thousands that are hatched. I have had correspondence with, or know personally, many, indeed I may say all, of the Game Bantam breeders of note, and I am perfectly satisfied that, with the exception of Mr. Crossland, they would endorse all that I have said in this subject.

Mr. Crossland, I dare say, bred an unusually large number of good birds last season, but that the majority of these were first-class I utterly disbelieve. In fact, I saw his Birmingham prize birds, for he sent them to me when we were some little time since negotiating for an exchange on approval. Now, though I suppose these were not the worst Mr. Crossland bred, they certainly were not first-class. The pullets had silvery deaf-ears; and the cock was, in my opinion, too dark, and did not carry his tail close or low enough for a first-class bird. Mr. Crossland must excuse my criticising his birds; he has brought them forward himself, or I should not have done so. I believe, however, that he has shown two of the best pullets of the season; they now, I think, belong to Sir St. George Gore; but I am inclined to think that with the exception of Mr. Hawkesley's celebrated bird (for which, by-the-by, I hear he has refused £20), I have shown the best two cockerels. In fact, Mr. Crossland, in a letter now before me, assured me that his strain of birds and mine are the best two out, and in proof that he believes so, he wished for a cock and two pullets which I showed at Manchester, to cross with his own two birds, though, as a rule, he evidently objects to crossing. I merely mention these facts to show "WILTSHIRE RECTOR" that I am not quite a novice, that I do not write altogether at random—in short, that I know something at least about the subject I am writing on.

But to return to Mr. Crossland's statement. I contend that if

it be true, as perhaps it is, that he has bred a larger proportion of good birds from a given number of chickens than any other breeder, it may fairly be attributed to his breeding in-and-in for so many years, so that he has fixed the breed to a certain extent, and I should certainly expect from such birds to obtain a larger number of good birds than if I bred from those obtained from sources of which I knew nothing; but I will venture to say that neither Mr. Crossland, nor any other breeder in England, can always breed from Game Bantams, or any other variety of poultry, a large proportion of first-class birds among the chickens reared. I say emphatically that any man who says that he can, is making a statement which will utterly mislead those who believe it. "WILTSHIRE RECTOR" will remember that his original statement was, that Game Bantams were so largely exhibited at Birmingham, because they are so easy to breed. I, and I think every one else who read his communication, understood him to mean breed good. If he meant that, then I have said what I think as to that; but if he meant that so many eggs are fertile, and consequently so many chickens may be reared, may I ask him whether this reasoning would not equally apply to the Black and White Bantams which our favourites are fast superseding?
